ANAXAGORAS

ANAXAGORAS, according to the most probable calculations, was born about the year 500 B.C. At his native town of Clazomenæ, in Asia Minor, he had, it appears, some amount of property and prospects of political influence, both of which he surrendered, from a fear that they would interfere with his search after the knowledge of nature. In early manhood he went to Athens, which was rapidly becoming the headquarters of Greek culture; and in that city he is said to have continued for thirty years. Here Pericles learnt to love and admire him; and the poet Euripides derived from him an enthusiasm for science and humanity. His influence was due partly to his astronomical and mathematical eminence, but still more to the ascetic dignity of his nature, and his superiority to ordinary weaknesses—traits which legend has embalmed. His observations of the celestial bodies led him to form new theories of the universal order, and brought him into collision with the popular faith which found the objects of its worship in the heavens. Anaxagoras had tried to reduce eclipses to the operation of known causes: he had removed the halo of deity from the sun, and profanely turned Apollo into a mass of blazing metal, larger than Peloponnesus; and he was even reported to have brought the phenomena of meteoric stones within the limits of predictable events. The dominant polytheism, and the ignorance of the multitude, could not tolerate such explanation; and the enemies of Pericles used the superstitions of their countrymen as a means of attacking the ideas of that statesman in the person of his friend. Anaxagoras was arrested on a charge of contravening the established dogmas of religion; and it required all the eloquence of Pericles to rescue him from the persecutors. Even then Athens could no longer be the sphere of his activity. He was forced to retire to Lampsacus, where he died about 428 B.C.

It is difficult to present the cosmical theory of Anaxagoras in an intelligible scheme. All things have existed in a sort of way from the beginning. But originally they existed in infinitesimally small fragments of themselves, endless in their number, inextricably mixed throughout the spaces of the world. All things were in that mass, but in the obscurity of indistinguishableness. There were the seeds or miniatures of corn, and flesh, and gold, in the primitive mixture; but these parts, of like nature with their wholes (the ὁμοιομερῆ of Aristotle), had to be eliminated from the complex mass before they could receive a definite name and character. The existing species of things having thus been transferred, with all their specialities, to the prehistoric stage, they were multiplied endlessly in number, by reducing their size through continued subdivision, at the same time that each one thing is so indissolubly connected with every other that the keenest analysis can never completely sever them. The work of arrangement, the segregation of like from unlike, and the summation of the ὁμοιομερῆ into totals of the same name, was the work of Mind or Reason. This peculiar thing, called Mind (νοῦς), was no less illimitable than the chaotic mass, but it stood pure and independent, a thing of finer texture, alike in all its manifestations, and everywhere the same. This subtle agent, possessed of all knowledge and power, is especially seen ruling in all the forms of life. Its first appearance, and the only manifestation of it which Anaxagoras describes, is Motion. Reason originated a rotatory movement in the mass (a movement far exceeding the most rapid in this present scene), which, arising in one corner or point, gradually extended till it gave distinctness and reality to the aggregates of like parts. But even after it has done its best, the original intermixture of things is not wholly overcome. No one thing in the world is ever abruptly separated, as by the blow of an axe, from the rest of things. The name given to it merely signifies that in that congeries of fragments the particular seed is preponderant. Every *a* of this present universe is only *a* by a majority, and is also in lesser number *b*, *c*, *d*.

Anaxagoras proceeded to give some account of the stages in the process from original chaos to present arrangements. The division into cold mist and warm ether first broke the spell of confusion. With increasing cold, the former gave rise to water, earth, and stones. The seeds of life which continued floating in the air were carried down with the rains, and produced vegetation. Animals, including man, sprang from the warm and moist clay. If these things be so, then the evidence of the senses must be held in slight esteem. *We* seem to see things coming into being and passing from it; but reflection tells us that decease and growth only mean a new aggregation and disruption. Thus Anaxagoras distrusted the senses, and gave the preference to the conclusions of reflection. People even said that he maintained snow to be really black; for was it not produced from the dark water?

Anaxagoras marks a turning-point in the history of philosophy. With him speculation passed from the colonies of Greece to settle at Athens. By the theory of minute constituents of things, and his emphasis on mechanical processes in the formation of order, he paved the way for the Atomic theory. By his enunciation of the order that comes from Reason, on the other hand, he suggested the theory that nature is the work of Design. But the features of this Reason he described in a vague and analogical way. Aristotle and Plato have blamed him for basing his explanations on natural, not on final causes. These charges are scarcely fair. Anaxagoras seems to have held that the order was the work of Mind; but he needed not on that account to assume what the order was, and then employ the conception to explain why things were so and so. The order is rather the general postulate which the details have to prove, instead of themselves resting upon it. The conception of Reason in the world passed from him to Aristotle, to whom it seemed the dawn of sober thought after a night of distempered dreams. From Aristotle it descended to his commentators, and under the influence of Averroes became the engrossing topic of speculation. The fragments of Anaxagoras have been collected by Schaubach (Leipsic, 1827), and Schorn (Bonn, 1829). See also Mullach, *Fragmenta Philos. Græc.* i. 243–252. (W. W.)

ANAXARCHUS, a Grecian philosopher of the Eleatic school, was born in Abdera, and flourished about 340 B.C. He was the companion of Alexander in his expedition into Asia, and seems, from anecdotes that have been preserved, to have enjoyed his intimate friendship. He checked the vainglory of Alexander, when, elated with pride, he aspired to the honours of divinity, by pointing to his wounded finger, saying, "See the blood of a mortal, not of a god." When Alexander was tortured with remorse at having slain his friend Clitus, Anaxarchus endeavoured to soothe him by saying, that "kings, like the gods, could do no wrong." It is said that Nicocreon, tyrant of Cyprus, commanded him to be pounded in a mortar, and that he endured this torture with the greatest patience; but the story is doubtful, having no earlier authority than Cicero. Regarding his philosophical doctrines we have no information. Some have inferred from the epithet εὐδαιμονικός ("The Fortunate"), usually applied to him, that he held the end of life to be Εὐδαιμονία.

ANAXILAUS of Larissa, a physician and Pythagorean philosopher, was banished from Rome by Augustus, B.C. 28, on the charge of practising the magic art. This accusation appears to have originated in his superior skill in natural philosophy, by which he produced effects that the ignorant attributed to magic. (Euseb., *Chron. ad Olymp.* clxxxviii.; St Iren. i. 13; Plin. xix. 4, xxv. 95, xxviii. 49, xxxii. 52, xxxv. 50.)

ANAXIMANDER, the second of the physical philosophers of Ionia, belonged, like his predecessor Thales, to the city of Miletus. His biography is a blank. The computations of Apollodorus have fixed the year of his birth at 611, and of his death a short while after 547 B.C. Tradition, probably correct in its general estimate, represents him as a successful student of astronomy and geography, and as one of the pioneers of exact science among the Greeks. But it is not to his delineations of the divisions of the globe, or to his dialling, or to his enlarged acquaintance with the celestial phenomena, especially of the obliquity of the ecliptic, that we can attribute the preservation of his name to the present day. That honour he owes to the broad views of the origin of things which his glimpses of natural knowledge suggested, and which he propounded in a treatise on nature or growth (φύσις). Of that work only a few words are left. The beginning or first principle (ἀρχή, a word which, it is said, he was the first to use) was an endless, unlimited mass (ἄπειρον), subject neither to old age nor decay, and perpetually yielding fresh materials for the series of beings which issued from it. It embraced everything, and directed the movement of things, by which there grew up a host of shapes and differences. Out of the vague and limitless body there sprung a central mass,—this earth of ours, cylindrical in shape, poised equidistant from surrounding orbs of fire, which had originally clung to it like the bark round a tree, until their continuity was severed, and they parted into several wheel-shaped and fire-filled bubbles of air. Man himself and the animals had come into being by like transmutations. Mankind was supposed by Anaximander to have sprung from some other species of animals, probably aquatic. But as the measureless and endless had been the prime cause of the motion into separate existences and individual forms, so also, according to the just award of destiny, these forms would at an appointed season suffer the vengeance due to their earlier act of separation, and return into the vague immensity whence they had issued. Thus the world, and all definite existences contained in it, would lose their independence and disappear. The "indeterminate" alone is perennial and godlike, all-embracing and all-guiding. The blazing orbs, which have drawn off from the cold earth and water, are the temporary gods of the world, clustering round the earth, which, to the ancient thinker, is the central figure. (See Ritter et Preller, *Historia Phil.* §§ 17–22; Mullach, *Fragmenta Phil. Græc.* i. 237–240.) (W. W.)

ANAXIMENES of Miletus may have been a younger contemporary of Anaximander, whose pupil or friend the ordinary tradition represents him to have been. To him it seemed that the air, with all its variety of contents, its universal presence, and all the vagueness which it has for the popular fancy as the apparent source of life and growth, was what maintained the universe, even as breath, which is our life and soul, sustains us. This vital air, boundless in its kind, is the source of the world's life. Everything is air at a different degree of density. Eternal movement pervades it; and under the influence of heat, which expands, and of cold, which contracts its volume, it gives rise to the several phases of existence. The process is a gradual one, and takes place in two directions, as heat or cold predominates. In this way was formed a broad disk of earth, which floats like a leaf on the circumambient air. Similar condensations produced the sun and stars; and the flaming state of these bodies is due solely to the extreme velocity of their motions. (See Ritter et Preller, *Historia Phil.* §§ 23–27; Mullach, *Fragmenta Phil. Græc.* i. 241–243). (W. W.)

ANAXIMENES, a Greek historian and rhetorician, was born at Lampsacus, in Asia Minor, in the 4th century B.C. He accompanied Alexander, whom he is said to have instructed in rhetoric, on his expedition against Persia. He wrote a history of Philip and of Alexander, and likewise twelve books on the early history of Greece, but only a very few fragments of these exist. The treatise Ῥητορικὴ πρὸς Ἀλέξανδρον, usually included among the works of Aristotle, has been ascribed by many critics to Anaximenes, on grounds that are generally admitted to be conclusive.

ANCELOT, Jacques Arsène François Polycarpe, a French dramatist and *littérateur*, was born at Havre, 9th Feb. 1794, and died 7th Sept. 1854. He completed his studies at Paris, where he made his literary début in 1819, with *Louis IX.*, a five-act tragedy, of which three editions were speedily exhausted. It had a run of fifty representations, and brought him a pension of 2000 francs from the king, Louis XVIII. His next work *The Mayor of the*

Palace, was played in 1823 with less success; but for it he received the cross of the Legion of Honour. Five years to a day after his *Louis IX.*, he produced *Fiesque*, a clever adaptation of Schiller's *Fiesco*. In 1828 appeared *Olga, or the Russian Orphan*, the plot of which had been inspired by a voyage he made to Russia in 1826, of which he also published an account in prose. About the same period he produced in succession *Mary of Brabant*, a poem in six cantos; *The Man of the World*, a novel in four volumes, afterwards dramatised with success; and in 1829 *Elizabeth of England*, which became very popular. By the revolution of July 1830 he lost at once his royal pension and his office as librarian at Meudon; and, obliged by the cares of a wife and family to resign a life of art for one of industry, he was chiefly employed during the next ten years in writing vaudevilles and light dramas and comedies, working, as he happily remarked, *pro fame* instead of *pro famâ*. A well-conceived tragedy, *Maria Padilla*, gained him admission to the French Academy, who chose him to succeed Bonald in 1841. Ancelot was sent by the French Government in 1849 to Turin, Florence, Brussels, and other capitals, to negotiate on the subject of international copyright; and the treaties on this question, which were concluded soon after, were the result, in a great measure, of his tact and intelligence.

ANCHISES (Ἀγχίσης), in *Greek Legend*, son of Capys and grandson of Assaracus, his mother being Themis, a daughter of Ilus, the founder of Ilium or Troy, to the ruling family of which, at the time of the Trojan war, he was also, on the paternal side, related, since Assaracus had been a brother of Ilus (*Iliad*, xx. 231–239). From the Assyrian character of the name Assaracus, from the intercourse between the Phœnicians and the early inhabitants of the Troad, and from the connection of Venus, the protecting goddess of the Phœnicians, with Anchises, it has been inferred that the family of the latter had originally come from somewhere near the centre of Assyrian influence. Venus met Anchises on Mount Ida, and, enamoured of his beauty, bore him Æneas (*Iliad*, ii. 820, v. 247). He was not to mention the mother of the child on pain of being killed by a thunderbolt from Jupiter. He did mention it, however, and, by one account, was slain as foretold; but according to others, was only wounded and blinded. In the more recent legend, adopted by Virgil, he was conveyed out of Troy on the shoulders of his son Æneas, whose wanderings he followed, it is differently stated, as far only as Sicily, where he was buried on Mount Eryx, or as far as Italy. On the other hand, there was a grave on Mount Ida at Troy pointed out as his. At Segesta in Sicily he had a sanctuary He was said by some to have had prophetic power. The scenes of his life represented in works of art are his being carried on the shoulders of Æneas, which frequently occurs on engraved gems of the Roman period; and his visits from Venus, which is rendered in a beautiful bronze relief, engraved in Millingen's *Unedited Monuments*, pl. 12.

ANCHOR, in *Navigation*, from the Greek ἄγκυρα, which Vossius thinks is from ὄγκη, a crook or hook, an instrument of iron or other heavy material used for holding ships in any situation in which they may be required to lie, and preventing them from drifting by the winds or tides, by the currents of rivers, or any other cause. This is done by the anchor, after it is let down from the ship by means of the cable, fixing itself into the ground, and there holding the vessel fast. The anchor is thus obviously an implement of the first importance in navigation, and one on which too much attention cannot be bestowed in its manufacture and proper construction, seeing that on it depends the safety of the vessel in storms. The invention of so necessary an instrument is to be referred, as may be supposed, to the remotest antiquity. The most ancient anchors consisted merely of large stones, baskets full of stones, sacks filled with sand, or logs of wood loaded with lead. Of this kind were the anchors of the ancient Greeks, which, according to Apollonius Rhodius and Stephen of Byzantium, were formed of stone; and Athenæus states that they were sometimes made of wood. These sorts of anchors retained the vessel merely by their inertia, and by the friction along the bottom. Iron was afterwards introduced for the construction of anchors, and also the grand improvement of forming them with teeth or flukes to fasten themselves into the bottom; whence the words ὀδόντες and *dentes* are frequently taken for anchors in the Greek and Latin poets. The invention of the teeth is ascribed by Pliny to the Tuscans; but Pausanias gives the merit to Midas, king of Phrygia. Originally there was only one fluke or tooth, whence anchors were called ἑτερόστομοι; but shortly afterwards the second was added, according to Pliny, by Eupalamus, or, according to Strabo, by Anacharsis, the Scythian philosopher. The anchors with two teeth were called ἀμφίβολοι or ἀμφίστομοι, and from ancient monuments appear to have been much the same with those used in our days, except that the stock is wanting in them all. Every ship had several anchors, the largest of which, corresponding to our sheet-anchor, was never used but in extreme danger, and was hence peculiarly termed ἱερά or *sacra*; whence the proverb *sacram anchoram solvere*, as flying to the last refuge.

Antiquity of anchors

Modern anchors

Up to the commencement of the present century what was termed the "old plan long-shanked" anchor seems to have been generally used. It was made of wrought iron, but the appliances of the anchor smith were so crude that little dependence could be placed upon it. About this time public attention was drawn to the importance of the anchor by a clerk of Plymouth yard named Pering, who published a book, and argued, from the number of broken anchors which came to the yard for repair, that there "must be something wrong in the workmanship—undue proportion or the manner of combining the parts." Mr Pering altered the sectional form, made the arms curved instead of straight, used iron of better quality, and introduced improvements in the process of manufacture. Since 1820 about 130 patents have been taken out for anchors; and the attention thus given to the subject, with the introduction of steam hammers and furnaces, the substitution of the fan blast for the old bellows, and the better knowledge obtained of the forgeman's art, have rendered the anchor of the present day so far superior to that of fifty years ago, that we rarely hear of one being broken, the ground in which it is embedded generally giving way before the anchor.

1. 2. 3.

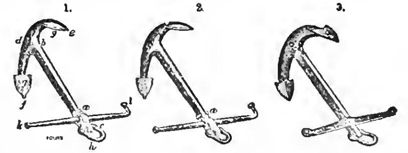

Fig. 1.—Common Anchor. Fig. 2.—Admiralty's. Fig. 3.—Rodger's

Common anchor.

Fig. 1 represents the "common" anchor. The various parts are known by the following terms:—The *shank* is the straight part, *ab*; the *square*, *ac*, is that part of the shank to which the stock and the shackle are attached; *d* is the *crown*; *de* and *df* the *arms*; *gg* the *palms* or *flukes*; the *pee* the *bill*, or the *point* is the extreme end of the arm beyond the palm; the *blade* is the part of the arm at the back of the palm; *h* is the *shackle* or *ring* to which the cable is attached, *kl* is the *stock*, placed at right angles

[1] The rules for the building and classification of iron ships provide that "their equipment is to be regulated by the *number* produced by the sum of the measurements of the half moulded breadth of the vessel amidships, her depth from the upper part of keel to the top of the upper deck beams, and the girth of her half midship section to the same height, multiplied by the vessel's length, for a one, two, and three decked vessel, and for a spar-decked steam vessel."

[2] Two of the bower anchors must not be less than the weight set forth above; in the third a reduction of 15 per cent. will be allowed.

Weight of Anchors supplied to Boats.—42 ft. Launch, 120 lb; 32 ft. Pinnace, 56 lb; 30 ft. Cutter, 40 lb; Jollyboats or Gigs, 30 lb.

to the plane of the arms and shank. The use of the stock is to "cant" the anchor. If it falls with the arms on the ground, the other end resting on the end of the stock, the pull of the cable will turn it over, so that the stock will lie upon the ground, and the weight of the crown and arms then resting upon the sharp point, will cause it to enter the soil and take fast hold.

The stock is made of iron in anchors of 60 cwt. and under, and of wood for anchors above that weight. A wooden stock (fig. 8) is made of English oak in two pieces; they are scored over the square so as to leave a space of about 2 in. clear between them at the shank and to touch at the extremities. It is made parallel for about 1/8th of its length at the centre, tapering from thence to the extremities, the side next the shackle being kept straight and the remaining three sides tapered. The section at any part is square, the dimensions being 1/10th of the length at the centre and half of this at the ends. The two pieces are fastened together by four iron bolts near the shank, six or eight treenails, and six iron hoops at the ends. The hoops are driven on tightly while hot, so that the contraction of the iron in cooling may draw the parts closely together. A projection, termed a *nut*, shown by the dotted lines at *a*, *a*, in fig. 8, is left on the square to prevent any lateral motion of the stock. An iron stock is made in one forging, so as to pass through a hole *a*, punched in the square. The stock has a shoulder *b*, which fits against the side of the shank when it is in the position for action as in fig. 1, and it is secured by a key driven tightly on the other side of the shank. The advantage of this is, that the stock can be unshipped and laid along the shank for convenience of stowing, as shown in fig. 4.

Fig. 4.—Iron stock unshipped for stowing.

The weight of the stock, whether of wood or iron, is about 1/4th that of the anchor.

The shank and each arm are forged under the steam-hammer in three pieces, and are then welded together at *m* and *n*, fig. 8. The welding is done by the "Hercules," which is a heavy iron ram placed over an anvil, so that it can be raised by steam power to a height of some 9 or 10 feet, and then let fall, being guided in its descent by three men, who hold rods attached to it. It is needless to say that the welding must be carefully done, as the whole strength of the anchor depends upon it.

Testing.

To ensure safety, every anchor should be tested at a public testing-house to 1/3d of its breaking strain. The anchor is held by a chain attached to the shackle, and the strain is applied to each arm separately at 1/3d of its length from the point. The proof of the anchor is that it must show no sign of fracture, and that if any deflection is caused by the strain, it must return very nearly to its original shape. A good anchor, after being deflected half an inch, will return to its former shape, leaving no permanent set.

Size of anchors.

The size of anchors for various ships has been determined by practice, but is based upon the theory that as the anchor is required to withstand the force brought upon the ship by the wind and tide, which would otherwise cause her to drift, its strength must be nearly proportional to her resistance. A result which will accord with sound practice may be obtained by calculating the resistance of a given ship at a speed of twelve knots, and taking this for the working load of the anchor. The working load should be half the testing strain, and consequently 1/6th of the breaking strength.

A large ironclad carries 8 anchors,—2 bower, 2 sheet, 1 stream, 1 stern, and 2 kedge. The bower anchors (fig. 7) are stowed at the bow, and are for ordinary use in a roadstead; if there is any difference in weight, the heavier is stowed on the starboard side, and is termed the best bower. The sheet anchors (fig. 8) are stowed as far forward as is convenient in the waist of the ship, and are sometimes called the waist anchors; they are only used in cases of emergency, or in the event of any accident befalling the bowers. The stream anchor is for use in a river or sheltered place, where a small anchor is sufficient to hold the ship. The stern anchor is used when it is required to moor at both head and stern, as is the case when there is not room for the ship to swing with the tide. The kedge anchors are generally of different sizes, one large and one small; they are used to warp the ship along a narrow channel, the kedge being carried out in a boat with the hempen cable attached to it, and dropped; the ship can then be hauled to the anchor. Kedge anchors are still supplied in the Royal Navy, but are very rarely used, the service for which they are intended being generally performed by the aid of a steam-tug vessel.

The tables on pp. 4 and 5 give the sizes and number of anchors and cables carried by ships of the Royal Navy, and those required by Lloyd's rules to be carried in merchant ships. The sheet and bower anchors are of the same size, and are given in the tables under the heading "Bower."

Committee of 1852. Public attention having been directed to the subject of anchors by the specimens which were exhibited at the Exhibition of 1851, a committee was appointed by the Admiralty in the succeeding year to consider and report upon the qualifications of the various kinds. The committee determined the qualities it was desirable for an anchor to possess, and assigned numerical values to each. The following tables give the result of their labours, showing the number of marks obtained by each anchor under trial :—

Table showing the relative order in which the several Anchors stand with regard to each of the properties essential to a good Anchor—the names arranged alphabetically.

ANCHORS	Strength computed from first crack.	Holding long and short scope.	Facility of stowing.	Quick holding.	Quick tripping.	Exemption from fouling.	Facility of sweeping.	Facility of transport in boats.	Fishing in a heavy seaway.	Canting.

Note.—This Table only professes to show approximate values, and has no pretensions to mathematical accuracy or precision.

The following is a recapitulation of the order in which the anchors were ranked by the committee, together with their relative percentage of inferiority or superiority to the Admiralty anchor the value of which, as given in the foregoing table (18·17), was taken as the standard or unit :—

Trotman's, . . .	1·28,	or 28 per cent. superior to Admiralty.			
Rodger's, . . .	1·26,	or 26	do.	do.	do.
Mitcheson's, . . .	1·20,	or 20	do.	do.	do.
Lenox's, ...	1·13,	or 13	do.	do.	do.
Honiball's, . . .	1·09,	or 9	do.	do.	do.
Aylen's, ...	1·09,	or 9	do.	do.	do.
Admiralty, . . .	1·	the standard.			
Isaac's, ...	·73,	or 27 per cent. inferior to Admiralty.			

The decisions of the committee have been much questioned, one of the objections being that the qualities of strength and holding on, neither of which is of any use without the other, were assigned such different values as 15 and 80; it has also been stated that the Admiralty anchor was treated unfairly, as one was taken promiscuously out of store for the trial, whereas the other competing anchors were made specially for it.

The Admiralty anchor (fig. 2) differs only from the ordinary anchor in having a *nut*, *a*, worked on the square, so that a wooden stock may be fitted temporarily if the iron stock is damaged, and that its proportions and form have been carefully considered and definitely fixed. Lenox's and Aylen's were modifications of the Admiralty anchor. Mitcheson's was of a difficult section to forge, and consequently expensive, and was withdrawn from the test of strength. Isaac's was of a peculiar construction, and may be passed over as more curious than useful.

Rodger's anchor, placed second on the list, was one of Captain Rodger's, R.N., who for the last forty years has devoted considerable pains to the improvement of anchors. Among his earlier inventions is an anchor with a *hollow shank*, to obtain greater strength with a given weight of iron; then an anchor without a palm, which he termed a "*pickaxe anchor;*" afterwards a "*small-palmed*" anchor; and by a patent taken in 1863, an "*indented small palmed anchor*" (figs. 3 and 7). The stock is of iron in large as well as small anchors, and is made with a mortice, to fit over the shank instead of passing through it. It is somewhat heavier than the stocks of other anchors; the arms are shorter than usual in proportion to the length of the shank, and are of a wedge shape, varying in sharpness from the throat to the head of the palms; the back part of the arms is parallel from palm to palm; the palm is double concave on the front, and has a small border at the edge for confining the soil through which it is dragged; it also has a large indentation on the back for the same purpose and to save weight; the shank is rectangular at its junction with the arms, and square close to the collar for the stock; the crown is made longer than usual, and has a large countersunk hole in its centre to save weight. It is claimed for this anchor that the peculiar form of the palms and arms, with the hole in the crown, give it great holding power, and that it will bury itself in the soil until the upper palm is beneath the surface, and consequently is not liable to be fouled by the cable. Rodger's anchor.

Trotman's anchor (fig. 5), which obtained the highest place in the committee's estimation, was an improved Honiball's (Porter's). The stock is of iron, similar to the Admiralty anchor; the shank is of rectangular section, somewhat larger at the centre than at the ends, and is made fork-shaped at one end to receive the arms; the arms are in one piece, and are connected to the shank by a bolt passing through their centre. The peculiarity of the anchor is that the arms pivot about this bolt, so that when it takes hold the upper fluke is brought in contact with the shank, thus reducing the height above ground, and rendering it almost impossible for the cable to get entangled round it, or, in other words, for the anchor to become foul. Trotman's anchor.

FIG. 5.—Trotman's.

Of the anchors tested by the committee, Trotman's

Rodger's, and the Admiralty find the most favour at the present time. Trotman's and the Admiralty have undergone no alteration, but Captain Rodgers has taken out two patents for improvements in his anchor since the committee reported.

Martin's anchor.

We now come to an anchor of entirely different shape from the preceding, patented by a Frenchman named Martin. The anchor is represented in fig. 6 in the position in which it lies on the ground just before taking hold. The shank is made in one forging, is of rectangular section, having a shoulder for the stock to fit against, and is increased both in thickness and area at the crown; the arms with the palms are forged in one piece, and then bent to the required shape; one of the arms is passed through a hole in the crown and is kept in position by a bolt screwed through the end of the crown, so that its point reaches a little way into an indent made for it in the round part at the back of the arms. Until very recently this securing bolt was placed in the shank in a vertical position (supposing the anchor to be lying with the palms horizontal), so as to cut into the hollow part at the front of the bent arm. A very strong shoulder is worked on the arms, so as to fit in a groove on one side of the shank, in such a manner that the arms will revolve through an angle of 30° either way. The stock is fitted over the shank as shown, and secured by a key, which fixes it tightly against the shoulder left on the shank. The advantages of Martin's anchor are as follows:—It is *self-canting;* it must fall in the position shown in the figure, and the weight of the arms, together with the pull of the cable, presses their sharp points into the soil, so that it takes hold immediately; it is impossible to foul it; it stows much more neatly than any other anchor; its holding power is very great, as both arms are in the soil at the same time, and the stock, which is flat and broad, adds materially to this quality; the strength is also very great. At an experiment made at Portsmouth dockyard in March 1867, two of the anchors were subjected to a strain of 50 per cent. over the Admiralty proof; the arms were deflected but three-tenths of an inch by this great strain, and when it was removed they regained their former shape. The anchor is made in three separate forgings without a weld. Unmasted turret ships, which have an all-round fire, are, almost without exception, fitted with Martin's anchor on account of the neatness with which it can be stowed, as the stock of any other anchor, if not unshipped, would obstruct the fire of the guns. The Admiralty allow a reduction of 25 per cent. in weight for Martin's anchor, using an 80 cwt. Martin where a 90 cwt. Admiralty or Rodger's anchor, weighing with its stock from 108 to 112 cwt., would be fitted, the weight given for Martin's anchor including the stock.

FIG. 6.—Martin's.

Stockless anchor.

Smith's patent stockless anchor has been highly spoken of. It is a modification of Martin's anchor, but without the stock.

Stowing bower anchor.

A bower anchor is stowed in H.M. service as shown in fig. 7. A, is the *cathead;* B, the *fish davit;* C, and E, *bollards;* D, the *bill-board.* The anchor is held in place by two chains, *a* and *b*, termed the *cat-stopper* and *shank painter* respectively, each of which is fitted with a long link at one end. A bolt *b*, about 5 or 6 inches long, is fixed on the side of the cathead, on a hinge at its lower end; it is held in the upright position by another bolt *c*, which passes through the cathead, and is worked by a lever *d; d* is provided with a hole at the end for a lanyard, so that two or three men can pull it. This whole arrangement is termed a *slip-stopper.* A somewhat similar combination of bolts and levers is fitted close to the bill-board D, *e* being a short bolt secured at its lower end with a hinge to the ship's side; and *f* a hooked lever which holds it in its upright position; *f* has a socket at its inboard end, to which a shifting arm, provided with a lanyard like the lever *d*, is fitted. The cat-stopper is rove through the shackle of the anchor, and the long link placed over the bolt *b;* it is then passed over a cleat *g*, on the side of the cathead, and belayed at the bollards C. The end of the shank painter is passed under the crown and over the shank; its long link is placed over the bolt *e*, and it is belayed at the bollards E. When it is desired to let go the anchor, the arm is shipped at *f*, and the lanyards at *f* and *d* are manned; then, at the word of command (given, if the ship is rolling, when she lurches towards the side on which the anchor is stowed), the men pull the lanyards, and *b* and *e* are released simultaneously, the links of the cat-stopper and shank painter drop off, and the anchor falls clear of the ship. In merchant ships it is not usual to fit the second slip-stopper, *b* and *e;* in this case it is necessary, before letting go, to "cock-bill" the anchor,—that is, to ease away the shank painter, so that the anchor hangs by the cathead alone. The next thing is to "weigh" the anchor. It is hove up by the capstan, and when it appears at the bows, the operations of "catting" and "fishing" have to be performed. A chain called the "cat pendant" is rove over the sheave *h* in the cathead, and shackled to a short piece of a similar chain attached to the anchor at one end, and stoppered to the cable at the other; the inboard end of the cat pendant is taken to a leading block on the opposite side of the ship, and a purchase tackle attached to it, so as to give the men a run right aft. When all is ready, the word is given, and the men run away with the purchase until the anchor hangs from the cathead instead of the hawse-pipe; it is then said to be "catted." A chain rove through the block at the head of the fish davit, and having a large hook at the end, is then hooked to the inner arm of the anchor, which is then raised and swung inboard (the fish davit being made to revolve), so that the fluke rests upon the bill-board D, and the anchor is "fished." The cat-stopper and shank painter are then rove, and all made ready to let go again at a moment's notice.

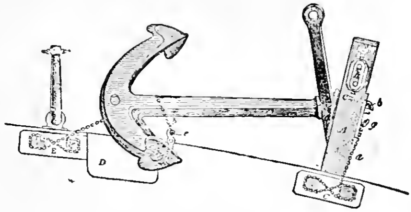

FIG. 7.—Bower Anchor, and manner of stowing.

The cathead shown in the figure is made of plates and angle irons, and is similar in shape to the old wooden catheads; it is fitted with a single sheave *h*, made to swivel so as to give a fair lead for the chain when the anchor is at the hawse-pipe. Catheads are frequently made of solid forgings, with a block hanging from the head for the cat pendant or fall. In ships designed for ramming, the cathead is made to revolve like the fish davit B, so that it can be turned inboard, and there will be no projection on the bow to foul the enemy's rigging.

Stowing sheet anchor.

Fig. 8 shows a sheet anchor as stowed in a man-of-war. The anchor rests upon stout iron rods, *a*, *a*, called tumblers; they are connected to the ship's side at the lower ends, so that they will fall outwards. *b*, *b*, are short bolts to keep the anchor in its proper position, with the tumblers slightly inclining outboard. Both *a*, *a*, and *b*, *b*, are fitted to the shank of the anchor, and so arranged that rope lashings

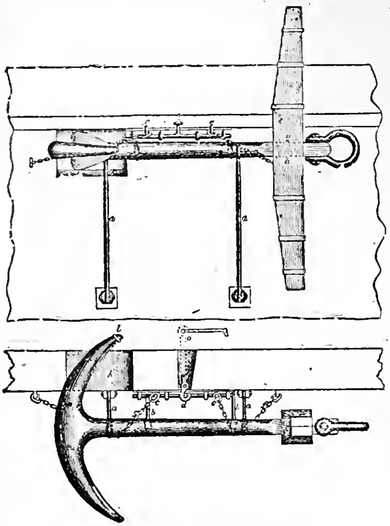

Fig. 8.—Stowing a Sheet Anchor.

passing round the shank can be secured to them. A strong bolt, fitted with three lugs, *c*, *d*, and *e*, is secured to the ship's side by eye-bolts, which allow it to revolve. Chains, *f* and *g*, fastened to the ship's side at one end, are passed round the shank of the anchor, and held by the lugs *c* and *e* at the other. A slip-stopper, *h*, clasps the lug *d*, and keeps the bolt in the position shown; the inner fluke of the anchor rests on the *bill-board k*, the point is held down by a securing chain fitted with a slip at *l*, and the upper end of the stock is secured in a similar way. When it is desired to "let go," the rope lashings on *a*, *a*, and *b*, *b*, are cut, the slips at the point and stock are knocked away, and then the stopper *h* is the only thing which holds the anchor. A shifting lever, shown by dotted lines, is fitted to a socket in *h*; when a strain is brought upon this, the lug *d* is released from the grip of the stopper *h*, and the anchor let go, the tumblers, *a*, *a*, throwing it clear of the ship.

It should be observed that whenever a slip-stopper is fitted, care must be taken, by placing a pin at the back of it, or otherwise, to prevent the anchor being let go by accident.

Stern and stream anchors are stowed at the stern of the ship in the way described for sheet anchors.

The kedge anchors are generally stowed in the main-chains.

Sheet, stream, and stern anchors being very rarely used, have to be re-stowed by the aid of the yard-arm, without any special appliances being fitted.

Mooring anchors.

Mooring anchors are those which are placed in harbours, &c., for the convenience of vessels frequenting them. A large *buoy* is attached to the end of the mooring cable, and the ship is made fast to a ring-bolt fitted on the buoy. Mooring anchors are not limited by considerations of weight, &c., as other anchors are, the only requirements being that they have sufficient holding power, and do not project above the ground, as any projection in the shallow waters in which they are usually placed would render ships liable to injury from grounding on them, and be dangerous to fishing-nets, &c. Mooring anchors may therefore be of stone, as shown in fig. 9; or of cast-iron, as in fig. 10. Mushroom anchors (fig. 11), first proposed for ships, are now only used for moorings. An old anchor which has one arm damaged is frequently used as a mooring anchor, the damaged arm being bent down close to the shank; the anchor is sunk with the bent arm uppermost, and there is no projection above the ground. In harbours where there is not much room it is usual to place two anchors, connected by a cable, in a line at right angles to the direction of the tide; a swivel is fitted at the centre of this cable, and the *buoy* chain is made fast to the swivel. With this arrangement the ship does not sweep such a large circle in swinging.

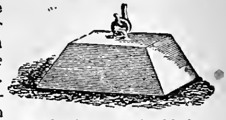

Fig. 9.—Buoy Mooring Block.

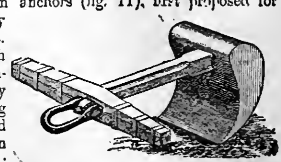

Fig. 10.—Cast-iron Mooring Anchor.

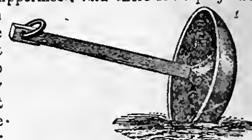

Fig. 11.—Mushroom Anchor.

The best mooring anchor which has yet been devised is shown in fig. 12. Its shank is a round bar of wrought iron, *a*, about 7 feet in length and 6 inches in diameter; it is increased at *b* to 9 inches diameter for about 1 foot of its length, and terminated at *f* similarly to the point of a gimlet; holes are made in the stout part *b*, and a screw flange of $3\frac{1}{2}$ feet diameter is cast around it; the molten metal gets into the holes and makes a good connection with the wrought-iron shank. A swivel *c*, to which a large shackle *d*, is attached, is fitted on as shown, and secured by a strong nut; the end of the shank *e* is made square. To place this anchor in about 8 fathoms of water, four iron bars, each about 17 feet in length, and provided with a socket at one end and a square head at the other, are used. As the anchor is lowered the socket of the first bar is fitted on at *e*, and the socket of the second bar in its turn fitted to the square end of the first, and so on till the anchor reaches the bottom. A drumhead, similar to a capstan, is then fitted on the last bar, and capstan bars shipped in it; by these means the anchor is turned round, and so screwed into the ground. It must be sunk through the soft mud or sand into the harder soil beneath it, and when this is done the holding power of the anchor is enormous. An anchor of the dimensions given weighs about 14 cwt., and will hold far more than a cast-iron mooring anchor of 7 tons. The only objections to it seem to be the difficulty of removing it if the moorings are required to be taken up, and that special appliances are required for putting it down.

Fig. 12.—Mooring Anchor.

Anchorage

A good anchorage is where there are from 10 to 20 fathoms of water, and the ground is not rocky or loose sand. Where there are more than about 20 fathoms the cable bears too nearly perpendicular, and is liable to trip the anchor. For anchoring in ordinary weather the length of cable veered out is about three times the depth of water. (T. M.)

ANCHOVY (*Engraulis*, Cuv.), a family of small fishes akin to the shad and the sprat, all three being of the *Clupeidæ*, or Herring tribe. There are six or seven species of anchovy found in the seas of Europe, of tropical America, and of India. Of these the most important and the largest is the common anchovy, *Engraulis encrasicholus*, so called from the bitter taste of its head, and the ancient belief that its bile was in that part. From the days of the Greeks and Romans it has been esteemed for its delicate and unique flavour; anchovy sauce is referred to under the name *garum* in *Horace*, Sat. ii. 8, 46. The common anchovy is from five to seven inches long, and resembles the sprat and sardine. Its distinguishing peculiarities are a short anal fin, the dorsal fin right over the ventral, a long sharp head with projecting upper jaw and mouth cleft behind the eyes, the colour rich bluish green on the back and silvery white on the belly, and large loose silvery scales. Anchovies are abundant on the coasts of Britain, but the markets are supplied chiefly from the Mediterranean fisheries, the best qualities coming from Gorgona, a small island near Leghorn. They leave the Atlantic depths, and come in shoals to the coasts of Spain, Portugal, France, and Italy, to deposit their spawn during the months of May, June, and July. Like herring they are caught with nets at night, being allured round the fishing-boats by fires kept burning at the stern. They are "headed," "gutted," pick'ed, and packed for exportation in barrels of five to twenty pounds, being repacked when brought to this country, and bottled up for use. Some relish them raw from the brine in which they are pickled; but they are commonly used in the shape of *sauce* or *paste*—a little vinegar, which dissolves the whole fish, including the bones, being used to produce the necessary consistence.

ANCHYLOSIS, or ANKYLOSIS (from ἀγκύλος, bent, crooked), stiffness of a joint, the result of injury or disease. The rigidity may be complete or only partial, and may be due to disease of the tendinous or muscular structures outside the joint, or to disease of the joint itself. When the structures outside the joint are affected, the term "false" anchylosis has been used in contradistinction to "true" anchylosis, in which the disease is within the joint. Anchylosis is also used as an anatomical term, bones being said to anchylose (or ankylose) when, from being originally distinct, they coalesce, or become so joined together that no motion can take place between them. The form *ankylosis* agrees best with the etymology.

ANCILLON, CHARLES, son of David Ancillon, and one of a distinguished family of French Protestants, was born 28th July 1659, at Metz, and died, 5th July 1715, at Berlin. He studied law at Marburg, Geneva, and Paris, where he was called to the bar. At the request of the Huguenots of his native place, he pleaded its cause at the court of Louis XIV., urging that it should be excepted in the revocation of the Edict of Nantes; but his efforts were so unsuccessful that he quitted the country and joined his father, who was already in Berlin. Through the influence of his father with the elector of Brandenburg, he was appointed at first judge and director of French refugees, and ultimately embassy counsel, historian to the king, and superintendent of the French school. He is known chiefly by his writings, several of which relate to the revocation of the Edict of Nantes, and other events of his time. He also wrote *Miscellaneous Literary Criticisms*, a *Life of Soliman II.*, and a *Treatise on Eunuchs*, the last of which he published under the name of *Ollincan*, an anagram of Ancillon.

ANCILLON, DAVID, an eminent French Protestant divine, father of the preceding, was born, 17th March 1617, at Metz, and died, 3d September 1692, at Berlin. At the age of sixteen he went to Geneva to complete his theological studies; and in 1641 he was appointed minister of Meaux, where he remained till 1653. At this time he accepted a call to his native town, Metz; and he continued to officiate there till 1685, when the revocation of the Edict of Nantes compelled him to retire to Frankfort. He left this for Hanau, and finally settled at Berlin, filling the office of French Protestant pastor there, much esteemed by the highest classes, till his death in 1692. He was a scholarly writer, and a man remarkable for the moral beauty of his character.

ANCILLON, JOHANN PETER FRIEDERICH, a historian and Prussian statesman, one of the family of French Protestant refugees noticed above, was born at Berlin, 30th April 1766, and died there, 19th April 1837. Descended from a family of divines, he early selected the ecclesiastical profession, and studied theology first at Berlin and then at Geneva. Shortly after finishing his course he was appointed minister to the French community at Berlin, as well as professor of history in the military academy, and he attracted attention even at court by the eloquence of his style. In 1793 he visited Switzerland and, a few years after, France, the details of his journeys and observations being published on his return. He was a frequent and able contributor to the literary journals of the period, and in 1801 appeared as the author of *Literary and Philosophical Miscellanies*, revealing a shrewd, philosophic cast of mind. Ancillon took rank among the most famous historians of his day by his next work, *A Picture of Political Revolutions in Europe since the 15th Century*, which gained him the eulogium of the Institute of France, and admission to the Royal Academy of Berlin. It is unfortunate that this work was never finished, for it is one of the ablest and most philosophical on the subject. The merits of Ancillon were not overlooked. He was appointed tutor to the prince royal of Prussia and his cousin in 1806, by Frederic William III., and received various appointments from the Government. In 1814 he accompanied the princes to Paris, and there became acquainted with Guizot, De Broglie, and other persons of eminence. After completing the term of his office as tutor, he was attached to the department of foreign affairs, and made a counsellor of state. He took an active part in many diplomatic transactions, rendering his country some signal services, and securing more and more the confidence of the court. Soon after the revolution of July 1830, he was made minister of foreign affairs, with the entire control of the whole department; and he retained the title of minister of state till his death. Besides the works already mentioned, he published, in 1817, *New Literary and Philosophical Miscellanies;* in 1819, *The Science of Politics;* in 1824, *Objects of Faith and Knowledge in Philosophy;* in 1829, *Thoughts on Man—his Relations and Interests;* and a number of other works on politics and philosophy.

ANCONA, a province of the kingdom of Italy, bounded on the N. by the Adriatic Sea and the province of Pesaro-Urbino, on the W. by Pesaro-Urbino and Umbria, on the S. by Macerata, and on the E. by the Adriatic. It forms part of the old district of the Marches, which passed from the dominion of the Pope to that of Victor Emmanuel in 1860. The Marches comprise the March of Ancona on the north and the March of Fermo on the south, although the whole territory is sometimes called the March of Ancona. The name, however, has long ceased to be the official designation of any part of Italy, and the present province of Ancona, which has an area of 740 square miles, and a population of 262,369, corresponds in extent neither to the March of Ancona, nor to the Papal delegation of the same name. There is little that is peculiar in the physical features of the province; the rivers are small and unimportant, and the hills are of no great height. Agriculture is the chief industry, and the soil, although naturally poor, yields large and profitable crops through the energy of its inhabitants. Considerable attention is also paid to the rearing of cattle and sheep, and the vine and the mulberry are grown to some extent. The cultivation of the silk-worm has not of late years been very successful, owing to the prevalence of disease in the worm. Chalk, sulphur, and raw petroleum are found in different parts of the province, but as yet little has been done to utilise those discoveries. The principal towns are Ancona, Jesi, and Osimo.

ANCONA, a city of Italy, and capital of the province of the same name, is pleasantly situated on the Adriatic, 132 miles N.E. of Rome, in a sort of amphitheatre between two hills—Monte Ciriaco and Monte Guasco or Conero. The streets are narrow and irregular, but the city contains some fine buildings, among which may be mentioned the cathedral of St Ciriaco (which is said to occupy the site of an ancient and famous temple of Venus), several of the churches, and the citadel. The harbour, one of the best on the Adriatic, is defended by several forts and protected by two moles. On the older of these moles there is a magnificent triumphal arch of Parian marble, erected in honour of the Emperor Trajan, by whom the mole was built, while the other mole possesses a second arch, of much inferior beauty, dedicated to Pope Benedict XIV. Ancona ceased to be a free port in 1869, and this circumstance, together with the gradual accumulation of mud in the harbour, and the conversion of a mercantile ship-building yard into a naval arsenal, has had a very unfavourable effect upon the commerce of the place. In 1843 the value of the imports was £1,020,770, and of the exports £428,219; in 1869 the respective amounts had decreased to £585,296, and £157,969. The chief articles imported are coal, hardware, sugar, fish, cottons, woollens, linens, lead, iron, and petroleum; while the chief exports are wheat, maize, wine, rags, liquorice, and manufactured goods; the principal manufactures of the town being silk, paper, tallow, wax, and leather. Ancona has a population of 46,000, many of whom are Jews and Greeks. The city was founded about 380 B.C. by Syracusan exiles, who fled from Sicily in order to escape the tyranny of the elder Dionysius. From its admirable position it rapidly rose in importance as a seaport, and it also became celebrated for its purple dye. The exact time of its subjection to the Romans is uncertain, but it was probably about 268 B.C., when the rest of Picenum came under the power of Rome. After the dissolution of the Western Empire, Ancona was plundered by the Goths, Lombards, and Saracens successively, but it always recovered its strength and importance, and eventually became a semi-independent republic, under the protection of the Popes. It continued in this position until 1532, when Clement VII. made himself master of it, and incorporated it with the Papal dominion. In 1797 it was taken by the French, who, in 1799, had in turn to surrender to a combined force of Austrians, Russians, and Turks, after a long and gallant defence under General Meunier. The French recovered possession of it in 1805, and soon after annexed it to their kingdom of Italy, but the Treaty of Vienna restored it to the Pope in 1815. In 1832 the French seized Ancona, in order to check the Austrians, who were then occupying Bologna and the surrounding country; and they retained possession of it until the Austrians evacuated the Papal territory in 1838. In 1860 Ancona was held by a hastily organised body of Belgians and Irishmen under the command of the French general, Lamoricière. It was here that Lamoriciere retired after his disastrous defeat at Castelfidardo by Cialdini, when Victor Emanuel determined on invading the Papal States. On the 29th of September (eleven days after Castelfidardo), Lamoricière capitulated at Ancona with his entire army. In 1861 the city of Ancona, like the rest of the province, became part of the new kingdom of Italy.

ANCUS MARCIUS, the fourth king of the Romans, succeeded Tullus Hostilius about 638 B.C., and reigned until 614. He defeated the Latins and other tribes, enlarged Rome by joining to it the Janiculum, and made the harbour of Ostia. In his reign many of the conquered Latins were incorporated with the Roman state, and not receiving the full franchise, formed, according to Niebuhr, the first elements of the Roman *plebs*.

ANCYRA. See ANGORA.

ANDALUSIA, or ANDALUCIA, an extensive region in the south of Spain, bounded on the N. by New Castile and Estremadura, on the W. by Portugal, on the S. by the Atlantic and the Mediterranean, and on the E. by the Mediterranean and Murcia. Although no longer officially recognised, yet, like the other ancient divisions of Spain, it is probably better known and oftener referred to, at least in popular language, than the modern provinces which have been formed out of it. These are eight in number—Seville, Huelva, Cadiz, Jaen, Cordova, Granada, Almeria, Malaga. It also corresponds to the "four kingdoms"—Seville, Jaen, Cordova, and Granada—into which the Moors divided the south of Spain, to the still older Roman province of *Bœtica*, and probably, in part at all events, to the Tarshish of the Bible, a famous trading emporium and district belonging to the Phœnicians, who were the earliest known inhabitants of the country. The name Andalusia is said to be a corruption of Vandalusia, from the Vandals, who overran this part of Spain after the downfall of the Roman Empire; other authorities, however, consider that the Moors, who occupied the country after the Vandals, gave it its present name from their term *Andalosh*, "land of the West." Andalusia has an area of about 33,000 square miles, and in 1867 had a population of 3,200,944. The principal river of Andalusia is the Guadalquivir, the Roman *Bœtis*, which rises in the mountains of Jaen, and flows in a south-westerly direction to the Mediterranean at San Lucar. Its chief affluents are the Jandula, the Guadiata, and the Huelba on the right, and the Xenil on the left. Among the other rivers of the province are the Tinto, the Guadalete, and the Guadaljorce. The country is very mountainous; the chief ranges are the Sierras Morena and de Arsohe in the north, the Sierra Susana in the centre, and the Sierras Nevada, de Gador, and Bermeja in the south. There are several peaks of great elevation; among the highest are Mulahacen (11,781 feet) and Picacho de la Veleta (11,597 feet), both in the Sierra Nevada. Many of the mountains abound with metals, as silver, lead, copper, iron, and with coal; while marble and quartz are also found, the former in large quantities, and of a fine quality. Though its soil and climate vary with the elevation of the land, Andalusia must be considered the finest and most delightful of all the divisions of the peninsula. Some of the higher mountains are covered with perpetual snow, a luxury which is highly prized by the inhabitants of the valleys, where the summer is usually extremely hot, and in winter the snow falls only to melt when it reaches the ground. Here the more common European plants and trees give place to the wild olive, the caper bush, the aloe, the cactus, the evergreen oak, the orange, the lemon, the palm, and other productions of a tropical climate. On the coasts of the Mediterranean, about Marbella and Malaga, the sugar-cane is successfully cultivated; and no inconsiderable quantity of silk is produced in the same region. Agriculture is in a very backward state, and the implements used are of the most primitive description; nevertheless, owing to the natural richness of the soil, large crops of wheat and other cereals are grown. There are, however, considerable tracts of land which, from want of water, are neither cultivated nor inhabited; these occur chiefly in the west of the province. The horses and bulls of Andalusia are celebrated all over Spain; sheep and swine are extensively bred, and game is abundant. The inhabitants are a lively, good-humoured, and ready-witted people, fond of pleasure, lazy, and extremely superstitious, great boasters, and, like most boasters, very cowardly and unwarlike. The men are tall, handsome, and well-made, and the women are among the most beautiful in Spain; while the dark complexion and hair of both sexes, and their peculiar dialect of Spanish, so distasteful to pure Castilians, are as evident traces of the long rule of the Moors, as are the magnificent architectural remains which adorn many of the Andalusian towns.

ANDAMAN ISLANDS. These islands lie in the Bay of Bengal, 590 geographical miles from the Hoogly mouth of the Ganges, 160 miles from Cape Negrais in British Burma, the nearest point of the mainland, and about 340 from the north extremity of Sumatra. Between the Andamans and Cape Negrais intervene two small groups, Preparis and Cocos; between the Andamans and Sumatra intervene the Nicobar Islands, all seeming to indicate a submarine range stretching in a curve, to which the meridian forms a tangent, between Cape Negrais and Sumatra, and though this curved line measures 700 miles, the widest sea-space is less than 90. Some zoological facts are held to point to the former existence of continuous land from Negrais to Achin Head. If we can accept the doubtful authority of Wilford, Hindu legends notice this remarkable chain, and ascribe it to Rama, who attempted here first to bridge the sea, an enterprise afterwards transferred to the south of India, and accomplished at the place we call Adam's Bridge.

The main part of the group is a band of four islands, so closely adjoining, end to end, but slightly overlapping, that they have long been known as one, viz., "the Great Andaman." The axis of this band, almost a meridian line, is 156 statute miles long. The four islands are (north to south)—North Andaman, 51 miles long; Middle Andaman, 59 miles; South Andaman, 49 miles, and Rutland Island, 11 miles. Of the three straits which part these four islands, the two most southerly, Macpherson's and Middle Straits, though narrow are navigable. Andaman Strait, between Middle and North islands, is at low water a fetid swampy creek, not passable by a boat.

Little Andaman, 30 miles by 17, forming the southern extreme of the group, is detached from Great Andaman by Duncan Passage, 28 miles in width. One considerable island (Interview Island) lies immediately west of Great Andaman, and many islets are scattered round. The highest point in the group is Saddle Mountain, in North Andaman, approaching 3000 feet. From this southward the hills sink in height.

People.—These islands, so near countries that have for ages attained considerable civilisation and have been the seat of great empires, and close to the track of a great commerce which has gone on at least 2000 years, continue to our day the abode of savages as low in civilisation as almost any known on earth. Our earliest notice of them is in that remarkable collection of early Arab notes on India and China which was translated by Eus. Renaudot, and again in our own time by M. Reinaud. It accurately represents the view entertained of this people by mariners down to our own time. "The inhabitants of these islands eat men alive. They are black, with woolly hair, and in their eyes and countenances there is something quite frightful. . . . . They go naked, and have no boats. If they had, they would devour all who passed near them. Sometimes ships that are windbound, and have exhausted their provision of water, touch here and apply to the natives for it, in such cases the crews sometimes fall into the hands of the latter, and most of them are massacred." The traditional charge of cannibalism has been very persistent; but it is entirely denied by themselves, and rejected by all who have taken part in our recent colony. Of their massacres of shipwrecked crews, there is no doubt; such horrors have continued to our own day on these islands, as well as on the Nicobars.

The people are *Oriental Negroes*, and idle stories were once current of their descent from wrecked cargoes of African slaves. Races of somewhat like character are found in the mountains of the Malay peninsula (*Semangs*) and in the Philippine group (*Ajitas* or *Aëtas*); there is reason to believe a similar race exists in the interior of Great Nicobar; there are recent rumours of the like in Borneo; and, strange to say, late research has shown a possibility of near connection with the Andamanners of the aboriginal race of Tasmania, recently extinct—circumstances which seem to indicate a former diffusion of this variety of mankind over a large space of the south-eastern world. But, in truth, accurate comparison of these tribes has yet scarcely been attained. The Andaman countenance has generally impressed Europeans at first as highly repulsive, and as African in character; but when we come to particulars, it has usually neither the exaggerated blubber-lip nor to a like extent the prognathous profile, of the true Negro; nor has the Andamanner the Negro's large or ill-formed feet. The ear is small and well-formed; the hair grows in short detached tufts, curled in small rings close to the head, but is declared not to be woolly. (There are tribes of a long-haired race on Interview Island, and it is also said on Rutland. These are of superior stature, and may have been modified by alien blood from shipwrecked crews.) The skin is of a lustrous black; the people, especially the men, are often robust and vigorous, though their stature is low—seldom 5 feet, and generally much less. In this respect they can look down on the Cape Boschmen alone. The general resemblance of countenance ascribed to the people in some accounts is entirely denied by those who have become familiar with them. Professor Owen, in a skull which he examined, found none of the distinctive characters of the African Negro. The people, as a rule, are absolutely devoid of clothing. The men's nearest approach to it is to twist a few fibres round the forehead or neck, or below the knee; the women sometimes make a slight attempt at decent covering with leaves or tails of plaited fibre—the last appearing to be only a modern innovation, and the result of partial contact with our settlement. Adult males are alleged to be tattooed, or rather cicatrised (though photographs do not confirm the universality of this). The process begins about the age of eight, and goes on at intervals. It used to be done with a flint; now usually with bottle-glass. Till the process is complete, the youth is ineligible for marriage. With both sexes all hair is shaven off, except a narrow strip from crown to nape, which is kept cut close. The men rarely have beard, and in general their eye-lashes are few. The people are neither long-lived nor healthy. Indeed, few are believed to pass forty. They suffer especially from fevers, colds, and lung complications; but also from bowel complaints, headache, toothache, abscesses, and rheumatism. The malarious influence of newly-cleared jungle affects them as violently as Europeans. Formerly their almost sole remedial treatment was to coat themselves in whole or part with mud and turtle-oil. This mud daubing in various forms is also used as mourning, and as a protection against musquitoes or the sun's rays. Paint made from ferruginous red earth is used as a decoration. Of late the natives round the colony appreciate quinine highly.

They have nothing whatever approaching to agriculture, nor does their rude shelter of leaves deserve the name of hut. Their chief food in the hot season consists of turtle, wild fruits, and honey, which they procure with great dexterity. In the rains the seeds of an *Artocarpus* are a staple, and in the intermediate season the wild hog; when the hog becomes scarce, fish and turtle. They have large appetites: a man will consume 6 lb of fish at a sitting, and soon be ready to begin again. At their haunts *kitchen-middens* are formed from bones and shells till the stench becomes unbearable; then they shift quarters. Col. Man mentions a kitchen-midden at Hope Town 15 feet high and nearly 50 in diameter, almost exclusively composed of shells. They seem kindly among themselves, and capable of strong attachments; and though irritable, they are not vindictive. They are very fearless, and are formidable archers, shooting strongly and truly with a bow between 5 and 6 feet long, of tough wood, hard to bend. They shoot and harpoon fish with skill, and catch it also by hand; and have hand-nets, and stake-nets for turtle.

Monogamy seems the rule. A young man proclaims himself a candidate for marriage by eating a special kind of fish (a species of ray), whilst marriageable girls wear certain flowers. The young man, if a pig-hunter, abstains from pork for a year; if a turtle-hunter, from turtle; and during the probationary year honey is forbidden. The wife provides shelter and mats to lie on, does the cooking (*all* food is cooked), procures water and shell-fish, carries loads, shaves and paints her husband, and tends him when sick. The husband protects his wife, makes canoes, weapons, &c., and sometimes goes in search of food; but this generally devolves on the unmarried. They pet their children, but many perish. A family of three living children is rare. If an adult dies, he is quickly buried, and the tribe migrates 8 or 10 miles for about a month. Some months later the bones, as they dry, are taken up, and these, the skull especially, are carried about by the kinsfolk—for how long we are not told. Mourning is shown by a daily daubing of olive mud, particularly a thick coat on the head. It lasts a month. During their sorrow they are silent, refrain from red paint and decoration, and from much food, especially from pork and honey; but have daily to throw a piece of honey-comb into the fire.

A notable eccentricity with these people is *crying*, as an utterance of emotion. It is an expression of reconciliation with enemies, and of joy at meeting friends after long separation. Something similar is known in New Zealand, and, it would seem, among the Patagonians. When two Andaman tribes meet under such circumstances, the new-comers begin the process, the women weeping first; their men then take up the lugubrious function; finally, the tribe on whose ground the scene occurs reciprocate, commencing with their women. This doleful antistrophé is continued long—"sometimes through several days"—and then they take to dancing!

They are said to have no idea of a God or future state, though Colonel Symes in his narrative gives a different account, and perhaps information on this point is still too imperfect. We find reference made to their belief that evil spirits cause disease, and to their dread of the ghosts of the dead.

They were always very hostile to strangers, repulsing all approaches with treachery, or with violence and showers of arrows. This may have originated in ancient liability to slave raids. Not till five years after the establishment of Port Blair colony did they begin to abate hostility. Robberies were frequent, and the murder of persons straying into the woods. The Government established *homes* for the aborigines in the environs of the settlement—viz., sheds for shelter, with some aid in rations, &c., and this conduced to a better state of things. An orphanage also has now been established under European matrons.

They are perfect swimmers and divers, and expert in managing canoes. These are neatly formed, and, according to Mouat, some are fitted with outriggers, which enable them to go seaward for considerable distances.[1] Two centuries ago, according to Captain A. Hamilton, they used to make hostile descents on the Nicobars, and this is confirmed by a Nicobar tradition mentioned in the *Asiatic Researches*.[2] But there is apparently no later evidence of such expeditions, and they were probably confined to March and April, when the sea is generally like a pond.

The number of aborigines is unknown, and conjecture has varied from 3000 up to 10,000, or even 15,000. Dr Mouat, in 1857, whilst steaming rapidly round the islands, everywhere saw natives in considerable numbers, and was induced to believe that the older and lower estimates had been much under the truth; but there is reason to believe that the population is on the coast only. They are divided into tribes or groups, not usually containing more than thirty individuals; and among these the country is partitioned in some fashion, for we are told that trespasses are a common ground of war between tribes. Each tribe has a depôt, or headquarters, where the sick are tended and surplus stores are kept.

The name *Mincopie* is applied to the Andaman race in books originating with a vocabulary given by Lieutenant Colebrooke.[3] One suspects some misunderstanding about this. Of the language we have as yet little information. It is said to be very deficient in words, and there is the tendency usual in the circumstances to strong dialectic differences. Thus the people of Little Andaman are said not to understand those of South Andaman. Those near the settlement begin to incorporate English and Hindustani words. It is stated positively that they have *no numerals*. It was once believed that they had no proper names, but this proves erroneous. The child is named before birth; hence names seem of common gender, and as they are few—some twenty in all—a special epithet is prefixed to each, personal or local in origin.

Climate.—This is very moist, as might be expected. The islands are exposed to the full force of the south-west monsoon of summer, and also in some seasons share that rainy effect of the north-east monsoon of the late autumn which characterises the Coromandel coast in the same latitude. Hence Colonel Kyd, who was chief of the settlement abandoned in 1796, says only four months' fair weather could be counted on, and a later explorer uses nearly the same phrase. The natives divide the year into three seasons—(1.) The dry, literally "the northern sun," February to May; (2.) The rainy, June to September; (3.) The moderate season, October to January. There is, however, rather a remarkable want of uniformity in the seasons. The rainfall at Port Blair for four years is reported as follows:—

1869,	155·7 inches.
1870,	119·9 "
1871,	100·09 "
1872,	103·02 "

The annual mean temperature, reduced to sea-level, is about 81° Fahr.

Geology, &c.—The islands appear from the sea as a series of low hills. These being covered with dense and lofty forest, we have as yet little information on the geology. The surface is excessively irregular, and the islands are too narrow to have rivers. There has been no alluvial deposit, and in many places the rocky formation is bare. Near our settlement in South Andaman the principal rocks are grey tertiary sandstones, identical with those prevailing in Aracan. This sandstone affords excellent building material. Traces of coal have been found, but only small pockets in the sandstone, without seam. Serpentine rock occurs on the east coast south of Port Blair, and on Rutland. A broad strip of indurated chloritic rock extends from Port Blair north-north-east to the east coast of Middle Andaman. Coral reef barriers gird the islands on all sides. The general dip of the rocks is to the westward, and thus the depth of sea on the east is much greater. On the west the corals are continuous and very extensive, forming patches of reef even 20 or 25 miles from shore. Agate flakes have been found on the site of an old encampment. It is curious that Captain A. Hamilton speaks of an adventurer known to him who made money by *quicksilver* obtained from these islands, but no confirmation of this has been reported. No fossils have yet been got.

Vegetation.—On the east the prevailing character is of forest trees with straight stems of 100 feet in mean height, often entirely covered with climbing plants. On the west vegetation is not so lofty. Deciduous trees are everywhere sporadic, and large tracts of them occur, robbing the landscape in the hot season of its tropical richness by their grey sterile aspect. These trees are generally of little utility. *Bombax malabaricum* is abundant among them. The immense buttressing of the stems of many of the trees is notable. Extensive tracts are also occupied by bamboo jungle, 30 to 35 feet high, almost entirely of *Bambusa andamanica*, from which lofty forest trees stand out, very far apart. The bamboo seems to attach especially to the indurated chloritic rock. Mangrove swamps fringe the little bays and straits, with many orchids. Behind the swamps are palms, *Phœnix paludosa* and *Licuala paludosa;* also *Barringtonia* and *Excœcaria Agallocha*, recognised by their red decaying leaves in June and July, and *Lagerstrœmia* and *Pterocarpus* by their rich lilac or yellow blossoms. Arborescent euphorbias, screw-pines, and a *Cycas* of considerable height, give a remarkable aspect to the coast vegetation in many places. Above these are the coast forests, on the slopes of hills, and valleys influenced by the sea. *Mimusops indica*, believed to be a very valuable wood, forms whole forests; sometimes in equal proportions with *Hemicyclia andam.* Around these are tropical mixed forests, through which it is hard to force a way from the multitude of climbers. *Dipterocarpus lævis* is the typical tree here. Palms are numerous—*e.g.*, *Licuala peltata* and *Areca triandra.* On one small island (Termooklee) there is a gigantic *Corypha* with leaves 30 feet long, but stemless. The high forests of the interior are little known. The quantity of intricate climbers is less, and the uniformity of vegetation greater. Treeless spots are confined to craggy islands completely exposed to wind and weather. The general character of the vegetation is *Burmese*, altered by some unfavourable circumstances, principally the scarcity of running water. But there are also a number of Malayan types not found on the adjacent continent. There are no tree ferns, apparently. There

[1] The native boats near Port Blair have no outrigger.
[2] ii. 344.
[3] *As. Res.*, iv. 392.

are a considerable number of edible wild fruits. No indigenous coco-palms exist, though these are so plentiful on the adjoining Cocos and Nicobars. Much of the scenery of the islands is very beautiful.

Animal Life.—This is greatly deficient throughout the whole group, especially as regards Mammalia, of which the species are very few. There is a small pig (*S. andamanensis*), important to the food of the people—perhaps that found on the Nicobars; a *Paradoxurus;* a rat with spiny hairs (*M. andam.*); a small frugivorous bat (*Cynepterus marginatus*). A "wild cat" is alleged, but there seems doubt about it. No Quadrumana have been seen. Of birds several species seem peculiar to this group, or to the Nicobars, or to the two together; and some of the Andaman species are considered by Mr Blyth to accord better with corresponding species at a distance than with those on the adjoining part of the contineut. Thus, *Artamus* and *Oriolus* of the Andamans seem identical with those of Java, not with those of India or Burma; and a shrike of these islands agrees better with a species of China and the Philippines than with the nearest species in Bengal, Aracan, and the Malay peninsula. Caves on the coast are frequented by the swift, which forms the edible nest of the China market. Pigeons, kingfishers, and woodpeckers are numerous. Reptiles are pretty numerous, both as regards species (15 to 20) and individuals, including eight *Ophidia* and several *Geckoes,* of which four or five are peculiar. Among these is one (*Phelsuma andam.*) the immediate kindred of which is known only in Madagascar and the adjoining islands. The Indian toad is common. Turtle are abundant, and now supply Calcutta. The species of fish are very numerous, and many are peculiar. They have been especially studied by Dr F. Day. It is much to be desired that these islands should have a thorough scientific exploration whilst the type of their productions is still substantially uninfluenced by foreign agency.

History.—It is uncertain whether any of the names of the islands given by Ptolemy ought to be attached to the Andamans; yet it is probable that this name itself is traceable in the Alexandrian geographer. Andaman first appears distinctly in the Arab notices of the 9th century, already quoted. But it seems possible that the tradition of marine nomenclature had never perished; that the Ἀγαθοῦ δαίμονος νῆσος was really a misunderstanding of some form like *Agdamán,* while Νῆσοι Βαρούσσαι survived as Lanka *Bálús,* the name applied by the Arabs to the Nicobars. The islands are briefly noticed by Marco Polo, who probably saw without visiting them, under the name *Angamanain,* seemingly an Arabic dual, "The two Angamans," with the exaggerated but not unnatural picture of the natives, long current, as dog-faced Anthropophagi. Another notice occurs in the story of Nicolo Conti (*circa* 1440), who explains the name to mean "Island of Gold," and speaks of a lake with peculiar virtues as existing in it (the natives do report the existence of a fresh-water lake on the Great Andaman). Later travellers repeat the stories, too well founded, of the ferocious hostility of the people; of whom we may instance Cesare Federici (1569), whose narrative e given in *Ramusio,* vol. iii. (only in the later editions), and in Purchas. A good deal is also told of them in the vulgar and gossipping, but useful work of Captain Hamilton (1727). In 1788–89 the Government of Bengal sought to establish in the Andamans a penal colony, associated with a harbour of refuge. Two able officers, Colebrooke of the Bengal Engineers, and Blair of the sea-service, were sent to survey and report. In the sequel the settlement was established by Captain Blair, in September 1789, on Chatham Island, in the S.E. bay of the Great Andaman, now called Port Blair, but then Port Cornwallis. There was much sickness, and after two years, urged by Admiral Cornwallis, the Government transferred the colony to the N.E. part of Great Andaman, where a naval arsenal was to be established. With the colony the name also of Port Cornwallis was transferred to this new locality. The scheme did ill; and in 1796 the Government put an end to it, owing to the great mortality and the embarrassments of maintenance. The settlers were finally removed in May 1796. In 1824 Port Cornwallis was the rendezvous of the fleet carrying the army to the first Burmese war. In 1839, Dr Helfer, a German savant employed by the Indian Government, having landed in the islands, was attacked and killed. In 1844 two troop-ships, "Briton" and "Runnymede," were driven ashore here, almost close together. The natives showed their usual hostility, killing all stragglers. Outrages on shipwrecked crews continued so rife that the question of occupation had to be taken up again; and in 1855 a project was formed for such a settlement, embracing a convict establishment. This was interrupted by the great mutiny of 1857, but as soon as the neck of that revolt was broken, it became more urgent than ever to provide such a resource, on account of the great number of prisoners daily falling into our hands. Lord Canning, therefore, in November 1857, sent a commission, headed by Dr F. Mouat, to examine and report. The commission reported favourably, selecting as a site Blair's *original* Port Cornwallis, but pointing out and avoiding the vicinity of a salt swamp which seemed to have been pernicious to the old colony. To avoid confusion, the name of *Port Blair* was given to the new settlement, which was established in the beginning of 1858. At the end of 1871 the number of convicts in the colony was 7603. For some time sickness and mortality were excessively large, but the reclamation of swamp and clearance of jungle on an extensive scale by Colonel Henry Man when in charge (1868–1870), had a most beneficial effect, and the health of the settlement has since been notable. Of late years the European detachment of 120 men has sometimes been without a man in hospital.[1] Cattle have been introduced in considerable numbers; extensive gardens have been planted, embracing many thousands of valuable fruit and timber trees. Mangoes, oranges, pommeloes, pine-apples, and jack-fruit are grown with especial success. The Andaman colony obtained a tragical notoriety from the murder of the viceroy, the Earl of Mayo, by a Mohammedan convict, when on a visit to the settlement, 8th February 1872. Recently the two groups, Andaman and Nicobar, the occupation of the latter also having been forced on the British Government (in 1869) by the continuance of outrage upon vessels, have been united under a chief commissioner residing at Port Blair. Steamers run from Calcutta to both groups monthly.

(See, among other works, Lieut. Colebrooke in *Asiatic Researches,* vol. iv.; *New Acc. of the E. Indies,* by Capt. A. Hamilton; *Adventures and Researches,* by Dr Mouat; Papers in the *Journal* and *Proceedings* of the As. Soc. Bengal; Kurz, *Report on the Vegetation of the Andaman Islands;* and other official documents.)

(H. Y.)

ANDELYS (Les), a town in the department of Eure, France, formed by the union of *Le Grand* and *Le Petit* Andely, which are situated, the latter on the eastern bank of the Seine, and the former nearly half a mile from the river, at a distance of about 20 miles north-east of Evreux. Grand Andely, the older of the two, dates from the 6th century, and contains a collegiate church, whose stained-glass windows are remarkably beautiful. Petit Andely sprang up around the château Gaillard, which was built by Richard Cœur de Lion in 1195, and was formerly one of the strongest fortresses in France. The chief manufactures at Les Andelys are cloth, thread, and leather, and there is a considerable trade in grain and wool. Population (1872), 5379.

ANDENNE, a town of Belgium, in the province of Namur, situated on the right bank of the Meuse, 10 miles east of Namur. It contains no buildings of note, but is a place of considerable manufacturing activity. The principal productions are porcelain, tobacco-pipes, and paper, and in the neighbourhood are beds of pipe-clay and marble quarries. Population, 6370.

ANDERNACH, a small town of Rhenish Prussia, situated on the left bank of the Rhine, 10 miles north-west of Coblenz. It is the *Antunnacum* of the Romans, and in the Middle Ages was a fortified town of considerable importance, but at the present day the walls only add to its picturesque appearance. Among the objects of interest are a lofty watch tower, the Coblenz gate, and the fine parish church, built in the beginning of the 13th century. Andernach has a trade in leather, corn, and wine; but its most noted articles of commerce are millstones, made of lava and of tufa-stone, which when pounded and mixed with lime, possesses the property of hardening under water, and has been much used by the Dutch as a cement in the construction of their dykes. Populatiou about 4000.

[1] In 1867 the mortality among convicts was 10·16 per cent., and in only one previous year had it been below that figure, often in excess. 1868 gave 3·9 per cent.; 1869 2 per cent.; 1870, 1·07 per cent.; 1871, about the same.

ANDERSON, ADAM, a Scottish economist, was born in 1692, and died in London on the 10th January 1765. He was a clerk for forty years in the South Sea House, where he published a work entitled *Historical and Chronological Deduction of the Origin of Commerce, containing a History of the Great Commercial Interests of the British Empire* (1762, 2 vols. fol.) A third edition appeared in 1797–9, in four vols. 4to, the last volume being an appendix and continuation by the editor, Mr Walton.

ANDERSON, ALEXANDER, an eminent mathematician, was born at Aberdeen about 1582. In his youth he went to the Continent, and settled as a private teacher or professor of mathematics at Paris, where he published or edited, between the years 1612 and 1619, various geometrical and algebraical tracts, which are conspicuous for their ingenuity and elegance. He was selected by the executors of the celebrated Vieta to revise and edit his manuscript works, a task which he discharged with great ability. He afterwards produced a specimen of the application of geometrical analysis, which is distinguished by its clearness and classic elegance. The works of Anderson amount to six thin 4to volumes, which are now very scarce. As the last of them was published in 1619, it is probable that the author died soon after that year, but the precise date is unknown.

ANDERSON, SIR EDMUND, a younger son of an ancient Scottish family settled in Lincolnshire, was born at Broughton or Flixborough about 1540, and died in 1605. He was some time a student of Lincoln College, Oxford, and removed from thence to the Inner Temple, where he applied himself diligently to the study of the law, and became a barrister. In 1582 he was made lord chief-justice of the common pleas, and in the year following was knighted. He was one of the commissioners appointed to try Queen Mary of Scotland in 1586. His works are—1. *Reports of many principal Cases argued and adjudged in the time of Queen Elizabeth in the Common Bench*, Lond. 1644, fol.; 2. *Resolutions and Judgments on all the Cases and Matters agitated in all Courts of Westminster in the latter end of the reign of Queen Elizabeth*, Lond. 1655, 4to.

ANDERSON, JAMES, LL.D., was born at the village of Hermiston, in the county of Edinburgh, in the year 1739. At an early age he lost his parents, who were in humble life, but this did not interrupt his education, and being desirous to obtain an acquaintance with chemistry as a means of professional success, he attended the lectures of Dr Cullen. Enlarging the sphere of his employments, Anderson forsook the farm in Mid-Lothian which his family had occupied for several generations, and rented in Aberdeenshire a farm of 1300 acres of unimproved land. But previous to this he had become known to men of letters by some essays on planting, which, under the signature "Agricola," he published in the *Edinburgh Weekly Magazine*, in 1771. After withdrawing from his northern farm, where he resided above twenty years, he settled in the vicinity of Edinburgh, and continued to interest himself in agricultural questions. In 1791 he projected a periodical publication called *The Bee*, consisting of miscellaneous original matter, which attained the extent of eighteen octavo volumes. It was published weekly, and a large proportion of it came from his own pen. From this period till 1803 he issued a number of publications chiefly on agricultural subjects, which had no small influence in advancing national improvements. Dr Anderson, after a gradual decline, partly occasioned by excessive mental exertion, died in 1808.

ANDERSON, JAMES, a learned and industrious antiquary of Edinburgh, was born there August 5, 1662, and educated to the legal profession, in which he became a writer to the Signet. His reputation as a historian stood so high, that just before the Union the Scottish parliament commissioned him to prepare for publication what remained of the public records of the kingdom, and in their last session voted a sum of £1940 sterling to defray his expenses. At this work he laboured for several years with great judgment and perseverance; but it was not completed at his death in 1728. The book was published posthumously in 1739, edited by Thomas Ruddiman, under the title *Selectus Diplomatum et Numismatum Scotiæ Thesaurus.* The preparation of this great national work involved the author in considerable pecuniary loss; and soon after his death, the numerous plates, engraved by Sturt, were sold for £530. These plates are now lost, and the book has become exceedingly scarce. After the union of the crowns, Anderson was appointed in 1715 postmaster-general for Scotland, as some compensation for his valuable labours; but in the political struggles of 1717 he was deprived of this office, and never again obtained any reward for his important services to his country.

ANDERSON, JOHN, natural philosopher, was born at Roseneath in Dumbartonshire in 1726. In 1756 he became professor of Oriental languages in the University of Glasgow, where he had finished his education; but in 1760 he was appointed to the chair of natural philosophy, a subject more suited to his tastes and acquirements. In this department he laboured assiduously to apply scientific knowledge to the improvement of the mechanical arts, studying industrial processes in the various workshops of the city, and thus qualifying himself to be the scientific instructor of the artizan. He opened a class for the instruction of mechanics in the principles of their arts, in which his familiar extempore discourses were illustrated by appropriate experiments. He is thus to be regarded as the father of those Mechanics' Institutions which have since become so common. His anxiety for the improvement of artizans was not confined to his personal exertions. Shortly before his death in 1796, he bequeathed the whole of his property to 81 trustees, for the purpose of founding an institution for educational purposes in Glasgow. He had seemingly intended it as a sort of rival to the university in which he was himself a professor; for his will mentions the founding of four halls or colleges with nine professors in each, for the faculties of arts, medicine, law, and theology. But the trustees found the funds entrusted to them utterly inadequate to so gigantic a scheme; and they contented themselves with founding what is now called, in its official calendar, *Anderson's University.* This institution was opened in 1797, by the appointment of Dr Thomas Garnett as professor of natural philosophy, who commenced with a popular course of lectures, which was attended by a considerable audience of both sexes. In 1798 a professor of mathematics and geography was appointed; and the institution has since had the aid of many able teachers. In 1799 Dr Garnett was succeeded by Dr Birkbeck, who had the merit of introducing in the institution a system of gratuitous scientific instruction, given annually to 500 operative mechanics. On the removal of Dr Birkbeck to the London Royal Institution, he was succeeded by Dr Andrew Ure in 1804; and Dr Ure by Dr William Gregory. In recent years the institution has received several munificent endowments from private persons, and its staff of teachers has been consequently greatly strengthened. It now possesses a complete medical school, whose certificates are recognised by the various examining bodies both in England and Scotland. In 1872–3 there were 460 medical students, and 2508 persons in all attended the various classes of the institution.

ANDERSON, ROBERT, an author and critic of considerable note in his own day, was born at Carnwath, Lanarkshire, on the 7th January 1750. He was at first destined for the church, and was sent to the University of Edinburgh in 1767. After a few sessions, however, he quitted the divinity classes in order to study medicine. He was for a short time employed as surgeon to the dispensary at Bamborough Castle in Northumberland. Returning to Scotland he took the degree of M.D. at St Andrews, on the 20th of May 1778. He now began to practise as a physician at Alnwick; but his general habits were rather those of speculation than exertion, and a moderate provision, acquired by his marriage with the daughter of Mr John Gray, of Alnwick, had emancipated him from the necessity of professional labour. In 1784 he finally returned to Edinburgh, where he continued to reside till the close of his life. For several years his attention was occupied with his edition of *The Works of the British Poets, with Prefaces Biographical and Critical* (14 vols. 8vo, Edin. 1792–1807). His other publications were, *The Miscellaneous Works of Tobias Smollett, M.D., with Memoirs of his Life and Writings* (Edin. 1796); *Life of Samuel Johnson, LL.D., with Critical Observations on his Works* (Edin. 1815); *The Works of John Moore, M.D., with Memoirs of his Life and Writings* (Edin. 1820); and *The Grave and other Poems, by Robert Blair; to which are prefixed some Account of his Life and Observations on his Writings* (Edin. 1826). Dr Anderson died on the 20th Feb. 1830.

ANDES. The Andes form a mountain chain second only to the Himalayas in the vastness of its proportions, and possessing many remarkable peculiarities. The origin of the name appears to be unknown, although numerous meanings have been authoritatively assigned to it. It has been variously supposed to be derived from the Peruvian words *Anta*, or tapir; *Anti*, meaning metal or copper; and *Antis*, the name of a tribe resident in the mountains; or from the Spanish *Andenes*, applied to the gardens on the terraces which occur on the western slopes of the Andes in Chili. Humboldt believes its meaning has been lost. In connection with this may be noticed the curious fact mentioned by Colonel Tod, that the Hindoos of North India called the Himalayas by the name Andes.

The Andes form a continuous belt of mountainous highland along the western margin of South America, and have been considered by many writers as the southern continuation of the Rocky Mountains, which form a similar belt along the west side of North America. There are many objections against this view, and in favour of that which makes the Andes and Rocky Mountains two distinct ranges. In New Granada, or Columbia, as it is now called, the eastern range of the Andes terminates on the western side of the Gulf of Maracaybo, near 72° W. long. South of the gulf a branch range is thrown off, which traverses Venezuela. The central range dies out in the low lands south of the junction of the Cauca and Magdalena rivers. The western range also lowers and spreads in breadth in advancing northwards, and is lost in the low flats along the south margin of the Gulf of Darien. At the neck of the Panama isthmus, the Naipi and Cupica valleys stretch from the Atlantic to the Pacific Ocean, and are nowhere more than a few hundred feet above the level of the sea. North of the Atrato a serpentine ridge of mountains occurs, which terminates in Cape Tiburon. It is crossed by a pass called Tanela, which is about 5 miles in length, and 130 feet above the sea. Most of the isthmus between 8° and 9° N. lat. is below the level of this pass. Here the Isthmus of Panama curves round westwardly; and west of Panama there is another broad low tract stretching right across. This district cannot be regarded as belonging in any way to the Andes. In Central America the mountains form numerous isolated ranges. In Mexico there are two high sierras. The eastern sierra does not reach the Rio Branco. The western sierra terminates at its north end in the Sierra Madre de Durango, which dies out in the northern part of Chihuahua and in Sonora, without being in any way connected with the Rocky Mountains.

The Rocky Mountains commence in about 100° W. long. at their south end, and terminate in about 145° W. at the north end, and have a general north-westerly direction. The Andes, on the other hand, commence near 54° S. lat. and 70° W. long. The southern portion forms a gentle curve, bending round to 73° W. in Patagonia, and reaching 70° again in the south of Chili. It continues on this line to Coquimbo, where it bends easterly, and after a slight double curve it cuts the meridian of 70° again south of Lake Titicaca. There is then a sharp bend, corresponding to that in the coast, which carries the range nearly to 80° W. in Ecuador, beyond which it again has an easterly bend, so as to cause it to terminate between 72° W. and 76° W. The north and south ends are consequently nearly in the same meridian. There are other dissimilarities between the Andes and the Rocky Mountains.

The formation of the Andes is due to several causes operating at distinct intervals of time. They consist mainly of stratified material which has been more or less altered. This material was deposited at the bottom of a sea, so that at some former time the highest portions were submerged, probably in consequence, to a certain extent, of subsidence of the sea bottom. Since the latest deposits there has been upheaval and denudation. The range, then, has resulted from the accumulation of sediment on a subsiding area; from the subsequent upheaval of such deposits, which have been increased in height by the ejection of volcanic products, and from the operation of denuding agents.

As far as our present knowledge goes, it appears to be probable that the Andes mark an area on which sedimentary deposits have been accumulated to a greater thickness than on any other portion of South America. It is further demonstrable that these deposits belong to several geological periods, the elevation having occurred at different periods, while their axes extend in different directions. Hence it is a complex range of mountains formed by the combination of several distinct systems of ridges. The width of the range varies from about 60 to 300 or more miles, but, as compared with other mountains, the Andes are for the most part narrow relatively to their height. Where their special features are most characteristically developed, they consist of a massive embankment-like foundation, rising with a rapid slope from the low country on either side, and having its margins surmounted by lofty ridges of ragged or dome-like summits. These Cordilleras, as they are usually termed, flank longitudinal valleys, or plain-like depressions which form the highest levels of the central portion of the gigantic embankment, and which vary in width from 20 to 60 miles. At intervals the longitudinal depression is broken up, either by ridges connecting the Cordilleras, or by lofty plateau-like uplands. In several cases these transverse ridges and belts of high ground form the main watershed of the country. They are rarely cut across by the river systems, whereas both the marginal Cordilleras are intersected at numerous points, and more especially by the rivers draining the eastern slope of the country. In no case do these eastern rivers originate to the west of the western Cordilleras. A few of the central valleys, or plain-like depressions, have no connection either with the western or eastern river system. Roughly speaking, the height of the central plains or valleys is from 6000 to 11,000 feet above the sea; of the passes and knots, from 10,000 to 15,000 feet; and of the highest peaks, from 18,000 to 23,290 feet—the last being the altitude of Aconcagua in Chili, which is generally considered to be the highest peak in America. Judging from these estimates, we may regard the bulk of the Andes as somewhere about that of a mass 4400 miles long, 100 miles wide, and 13,000 feet high, which is equivalent to 5,349,801,600,000,000 cubic feet. On this basis we find that the Mississippi would carry down an equivalent mass of matter in 785,000 years. The rate of denudation in certain river basins varies from one foot in 700 years, to one foot in 12,000 years. Assuming that similar rates would apply to the Andes, they would be denuded away in from 9 to 156 million years. In all probability, much less than 9 million years would suffice. On the other hand, the Andes would be swept away in 135,000 years, supposing the denuding powers of the globe were concentrated on them alone. From the above data, and assuming the average specific gravity of the matter forming the Andes to be 2·5, the weight of the portion above the sea may be estimated at 368,951,834,482,750 tons, giving an average of about 1000 tons on each square foot at the level of the sea. Under Aconcagua the pressure would be about 1780 tons per square foot at the same level, provided, of course, it were not, as it no doubt is, more or less modified by lateral pressure. These figures afford some, though at best a vague, conception of the mighty grandeur of this range of mountains, and of the scope there is for the exertion of enormous pressure. How vast, then, must be those forces which have counteracted such pressures, and upheaved the ocean-spread sediments of the continent, until the Andes, that—

> "giant of the Western Star,
> Looks from his throne of clouds
> O'er half the world !"

But, however vast the Andes may seem to us, it should be remembered that they form but an insignificant portion of the globe itself. Aconcagua is about $\frac{1}{2000}$th of the earth's diameter, which is relatively not more than a pimple $\frac{1}{30}$th of an inch high on the skin of a tall man.

The range may be considered as commencing on the south with Cape Horn, although for several degrees it is much broken up by arms and straits of the sea. The first portion of any extent commences between Cape Good Success and Cape San Paulo, and stretches across Tierra del Fuego, by Mount Darwin and Mount Sarmiento, and the range of hills on either side of Admiralty Sound. The mountains named are from 6600 to 6800 feet high. The Strait of Magellan also cuts through and across the range, isolating the mountainous islands of Clarence and Santa Ines. Otway Water cuts through the range, and penetrates to the plain of Patagonia. North of this are several snowy eminences, and in some places glaciers descend almost to the sea-level. At Last Hope Inlet, or a little north of 52° S., we have the commencement of the Andes as a continuous range, Disappointment Bay being the most northern place where the Pacific reaches the plains to the east of the Andes. South of this, and for several degrees to the north, the islands which fringe the coast have a mountainous character, and appear to belong essentially to the Andes range, with which there is reason to believe they were once connected. Along this space the Andes encroach upon the ocean, and have no western slope proper. Many of the sea channels are very narrow and ravine-like in character; they appear to represent a valley between two ridges of mountains,—a feature which is most conspicuous farther north. The highest part or crest of the range is close to the sea, and consequently the streams which fall into the Pacific are all small. Towards the south the width is about 20 miles; and in the latitude of Mount Stokes, which is 6400 feet high, it is 40 miles. North of this the range is in places more than 40 miles across. From 46° to 42° S., the mountains become somewhat higher, the loftier peaks ranging from 4000 to 8000 feet. Among the more conspicuous are Mount Yanteles, 8030 feet; Mount Melimoyu, 7500 feet; Mount Corcovado, 7510 feet; and Mount Minchinmadiva, 7406 feet above the sea-level. The Eyre Sound glaciers descend to the sea-level. At about 41°30′ S. lat. there is a low pass across the Andes; and to the north of this the slope is more or less distant from the sea, except, perhaps, at one part where the desert of Atacama terminates in lofty cliffs on the shore. In Chili the Andes increase in height and width, and between about 38° and 28° S. run approximately north and south; and nowhere do they recede so far from the sea as in the southern part of Chili. At this part, or in about the latitude of Antuco (36° 50′ S.), the lower land on the west is more than 100 miles broad, and the width of the range itself is probably more than 100 miles. Here the Andes consist of two ranges, the crests of which are from 60 to 80 miles apart, enclosing a longitudinal valley. Across these ranges there is a pass, which, with the exception of those near the mountains Osorno and Villarica, is the most southern in Chili. The summit of this pass is not more than 12,000 feet above the sea. The pass of Planchon lies north of Mount Descabezado; and to the south of Peteroa is the pass of Las Damas, which is probably not more than 11,000 feet at its highest point. At the head of the Maypu valley a pass traverses the two ranges of the Andes as well as the included valley of Tunuyan. That through the western range is called Peuquenes Pass, and rises to 13,210 feet above the sea-level; while that through the eastern range is called Portillo, and rises to 14,365 feet above the sea. Near 32° 38′ S., Aconcagua rises to 23,290 feet, and is, so far as known, the highest peak in America, and the highest volcano in the world. A little to the south of it is the Cumbre or Uspallata Pass. In the western range it rises to 12,454 feet above the sea; and on its north flank is the pass of Los Patos. At about 30° S. the mountainous system becomes more complicated, owing to the appearance of several ranges which rise out of the plains towards the north-west corner of the Argentine Confederation, some of which run north and join the lofty highlands of the Bolivian Andes. It is doubtful whether all strictly belong to the Andes. Thus, in the latitude of Coquimbo, where both the mountains and the coast line trend somewhat to the east of north, there are three parallel mountain ranges. The western is called the Andes, the central range is known as the Sierra Famatina, and the eastern as the Sierra Velasco. The two latter ranges are quite isolated from the first-mentioned range, terminating abruptly on the north and south. North of 28° S., however, a number of sierras which rise from the Argentine plain form an extensive mass of mountains. These are continuous into the Cordilleras de los Valles, de Despoblado, and Abra de Cortaderas, which form the eastern margin of the lofty mountain plains of Bolivia. These plains slope down from the eastern side of the Andes, just as the Atacama desert seems to form part of the western slope. At about 22° S, the Andes begin to trend somewhat to the west of north. At about 20° S. the eastern and western ranges are connected by a lofty transverse chain about 60 miles broad, and similar to the mountain knots of Peru. North of this the ranges bend more to the west, and enclose the extensive valley of the Desaguadero river and Lake Titicaca, which is shut in on the north by the transverse chain of the Vilcañota Mountains. The width of the range is in this part from 200 to 250 miles; or if the offset running eastward to Santa Cruz be included, the width is between 500 and 600 miles. One special feature about this part of the range is, that the Desaguadero valley (13,000 feet above the sea) is the largest in the Andes which has no connection with the river systems on the outer flanks, whether to the east or to the west. There are one or two small ones of a similar kind in the north-west part of the Argentine Confederation. The highlands which surround this great valley (which might be appropriately called the navel of South America) form a continuous re-entering watershed, separating respectively the numerous small rivers flowing into the Pacific, the Amazon system, which drains a large portion of the northern part of South America, and the La Plata system, which drains most of the southern part of the same area. In this region, too, more especially in the eastern Cordillera, it was for a time believed, on the authority of Mr Pentland, that the highest peaks of the Andes were situated; his first estimates were, however, ascertained by himself and others to have been too great. The highest peak is the Nevado de Sorata, close to Lake Titicaca, and estimated at 21,286 feet high; next to it comes the twin peaked Illimani, a little further south, which rises to 21,181 feet. The passes crossing the valley have summits averaging 14,000 feet, but the one which skirts the Nevado de Sorata rises nearly to 16,000 feet above the sea. From about 18° the Andes, like the coast, runs north-west, so that whereas in about 18° S. the crest of the western Cordillera is in 70° W. long., at 14° S. it has reached a little beyond 75°. Here there is another change of direction, this portion of the western Cordillera stretching from about 14° S. to 6° S., the south end being near 75° W., and the north near 80° W., the westing being rather more than half a degree per degree of latitude. From 6° S. to the equator the direction is very slightly to the east of north; beyond this the trend is still more east, so that the termination of the west Cordillera lies between 76° and 78° W. long. in between 7° and 8° N. lat. The northern end of the eastern Cordillera is near 72° W. Returning again to the Peruvian Andes, we find some lofty peaks which rival, and it may be surpass, those of Bolivia. Thus Sehama is reputed to be 22,000 feet; Chungara somewhat less; Chipicani, 18,898 feet; Arequipa, 18,373; Chuquibamba, 21,000 feet. There are numerous passes over the Andes in Peru, such as those of Gnalillos, of the Altos de los Huescos, and of the Altos de Toledo—the first mentioned of which rise to 17,820 feet above the sea. North of the Vilcañota Mountains the eastern portion of the Andes is much cut up by the numerous feeders of the Ucayali and Madeira rivers, most of which originate on the flanks of the western Cordillera. At Pasco there is a lofty mountain knot or table-land, which connects the Cordilleras, and at the same time forms the watershed between the upper portions of the basins of the rivers Ucayali, Huallaga, and the Marañon, or Upper Amazon. From this table-land three Cordilleras extend northward, of which the eastern dies out between the Ucayali and Huallaga rivers; the central between the Huallaga and the Upper Amazon; while the western Cordillera is continuous into the mountain knot of Loja, which forms the southern portion of the Andes of Ecuador, and which is estimated to be 11,650 square miles in extent. From this knot two lofty Cordilleras, abounding in volcanoes, both active and extinct, run nearly parallel. They are separated at intervals by transverse ridges into three vast mountain valley plains, of which the two southernmost drain into the Amazon basin, and the northernmost into the basin of the Esmeraldas river. The two Cordilleras are again united in the north by the mountain knot of Los Pastos, on the borders of Ecuador and Columbia. The valley plains are about 40 miles wide. On the south is the valley of Cuenca, which is about 50 miles long, and about 7800 feet above the sea. From it the way into the central valley plain, that of Ambato, is across the transverse ridge by the pass of Assuay, which rises to 15,520 feet. It is about 130 miles long, and about 8000 feet above the sea. The mountain fringe comprises several important volcanoes, viz., Sangay, Tunguragua, and Cotopaxi in the eastern Cordillera; and the volcano Carguirazo in the western Cordillera, which also includes the lofty Chimborazo, estimated to reach 21,424 feet above the sea. Then crossing over the low transverse ridge of the Alto de Chisinche, we descend into the valley-plain of Quito, which is bordered by one of the most intensely volcanic areas on the globe. To the east are Sinchulagua, Antisana, and Cayambe; the last is now extinct, stands on the equator, and is 19,534 feet above the sea. It is the highest point on the equator in the globe, and is the only one along that line where perpetual snow exists. In the western Cordillera the prominent eminences are Pichincha and Imbabura. The valley-plain is about 9500 feet above the sea. Taking Cotopaxi as a centre, Orton observes that the other peaks may be arranged in concentric orbits thus. Ruminaqui and Sinchulagua are 10 miles distant; Iliniza, Corazon, Atacatzo, and Antisana are 25 miles; Quirotoa, Pichincha, and Guamani are 30 miles; Llanganati is 40 miles; Tunguragua, Carguirazo, Cayambi, are 50 miles; Chimborazo, Imbabura, and Cotocachi, are 60 miles; Altar is 65 miles; Sangay is 75 miles; lastly, Chiles and Assuay are 100 miles. Chimborazo is the most conspicuous feature in this part of the Andes, and from one point its outline resembles that of a lion at rest. Cotopaxi is the most symmetrical active volcano on the globe. Its apical angle is 122° 30′; and the slope is a little over 30° on the south, west, and east sides, and nearly 27° on the north side. Its summit was attained for the first time on November 27, 1872, by Drs Reiss and Stübel. The height was found to be about 19,500 feet. Beyond the mountain knot of Los Pastos two Cordilleras run in a north-easterly direction to about 2° N. The western Cordillera is broken by the valley of the Patia, which has its source on the slopes of the valley between the mountain knot of Los Pastos and the transverse ridge south of Popayan. The eastern Cordillera is continued into the Paramo de Guanacas, from which basis the Andes spread out fan-like into three Cordilleras. This paramo, like the cross range between Iliniza and Cotopaxi, forms part of the main watershed between the rivers draining into the Atlantic and Pacific Oceans. North of the paramo this watershed runs along the western Cordillera for some distance, and then crosses several minor ranges of hills with their intervening valleys. The low watersheds at the head of the Atrato basin coincide with it; and north of Cupica Bay it suddenly bends, passing from within a few miles of the Pacific to within a few miles of the Atlantic Ocean. Having commenced this general account of the Andes with a notice of the mountain ranges of Columbia, and of the lowlands of the Isthmus of Panama, we thus come round to our starting-point. In the article AMERICA there is a brief account of the chain from a geological point of view, as well as of the transverse chains of South America; and under the heads of the various countries through which these pass further particulars are given.

The following references will assist the reader who wishes to enter more minutely into this subject:—Humboldt's works on South America; his papers in the *Journal de Physique*, vol. liii. p. 30 (1801); another in Gilbert's *Annalen*, vol. xvi. pp. 394, 450 (1804); Pentland's papers in *Phil. Mag.*, vol. ix. p. 115 (1828), and in the *Journal of the Roy. Geog. Soc.*, vol. v. p. 30 (1835); papers by Pissis in *Comptes Rendus*, vol. xl. p. 764 (1855), and vol. lii. p. 1147 (1861), as also in *Annales des Mines*, fifth series, vol. ix. p. 81 (1856); D. Forbes, "On the Geology of Bolivia and South Peru," in *Q. Jour. Geol. Soc.*, vol. xvii.

ANDOCIDES, a Greek orator and diplomatist, was born at Athens in 467, and died about 391 B.C. After holding a command for a time in the Athenian fleet, he was engaged in various embassies to foreign states. In 415 he was implicated with Alcibiades in the charge of mutilating the busts of Hermes, suspicion being specially roused against him from a large bust near his house having been almost the only one that was left entire. On the information he gave against others, they were put to death; and Andocides himself was deprived of his rights of citizenship, and went into exile. He returned to Athens on three different occasions, and though he was as many times driven again into banishment, he appears to have held a position of trust and influence in the city from 403 to 393. Three orations of his—*De Reditis*, *De Mysteriis*, and *De Pace*—are extant, which are of great historical value. The authority of a fourth, *Contra Alcibiadem*, which has been attributed to him, is disputed on what appear to be good grounds. Andocides was one of the ten Attic orators, whose lives were written by Plutarch.

ANDORRE, or ANDORRA, a small semi-independent state on the south side of the Pyrenees, between the Spanish province of Lerida and the French department of Ariège. It is surrounded by mountains, and consists of one main valley, which is watered by the Balira, a tributary of the Segre, which itself flows into the Ebro, and of several smaller valleys, the most important of which are those of the Ordino and the Os. It has an area of about 150 square miles, and is divided into six parishes, Andorra la Viéja (the capital), San Julian de Loria, Canillo, Encamp, Ordino, Massana. The population is under 7000. The territory was once densely wooded, whence probably its name, from the Arabic *Aldarra*, "a place thick with trees;" but the forests have been almost entirely destroyed for fuel. The pasturage is extensive and excellent; the mountains contain iron and lead mines; rye, potatoes, fruits, and tobacco, are grown on the lower grounds; game and trout are abundant. The population is rather pastoral than agricultural; but smuggling, together with the manufacture of tobacco, occasions some traffic. The Andorrans are a robust and well-proportioned race, of an independent spirit, simple and severe in their manners, but mostly ignorant and ill-educated, although they receive instruction gratuitously at the parish schools; they speak the Catalan dialect of Spanish, and are all Roman Catholics. This remarkable little state is a surviving specimen of the independence possessed in mediæval times by the warlike inhabitants of many Pyrenean valleys. Its privileges have remained intact, because the *suzeraineté* of the district became equally and indivisibly shared, in 1278, between the bishops of Urgel and the counts of Foix; the divided *suzeraineté* being now inherited by the French crown and the present bishop of Urgel, and the two powers having mutually checked innovations, while the insignificant territory has not been worth a dispute. Thus Andorra is not a republic, but is designated in official documents as the "Vallées et Suzeraineté." Before 1278 it was under the *suzeraineté* of the neighbouring counts of Castelbo, to whom it had been ceded, in 1170, by the counts of Urgel. A marriage between the heiress of Castelbo and Roger Bernard, count of Foix, carried the rights of the above-named Spanish counts into the house of Foix, and hence, subsequently, to the crown of France, when the heritage of the feudal system was absorbed by the sovereign; but the bishops of Urgel claimed certain rights, which, after long dispute, were satisfied by the "Act of Division" executed in 1278. The claims of the bishopric dated from Carlovingian times, and the independence of Andorra, like most other Pyrenean anomalies, has been traditionally ascribed to Charlemagne. Preserved from innovations by the mutual jealousy of rival potentates, as well as by the conservative temper of a pastoral population, Andorra has kept its mediæval usages and institutions almost unchanged. In each parish two *consuls*, assisted by a local council, decide matters relating to roads, police, slight taxes, the division of pastures, the right to collect wood, &c. Such matters, as well as the general internal administration of the territory, are finally regulated by a *conseil général* of 24 members (4 to each parish), elected, since 1866, by the suffrages of all heads of families, but previously confined to an aristocracy composed of the richest and oldest families, whose supremacy had been preserved by the principle of primogeniture. A general syndic, with two inferior syndics, chosen by the *conseil général*, constitutes the supreme executive of the state. Two *viguiers*—one nominated by France, and the other by the bishop of Urgel—command the militia, which consists of about 600 men, although all capable of bearing arms are liable to be called out. This force is exempt from all foreign service, and the chief office of the *viguiers* is the administration of criminal justice, in which their decisions, given simply according to their judgment and conscience, there being no written laws, are final. Civil cases, on the other hand, are tried in the first instance before one of the two *aldermen*, who act as deputies of the *viguiers*; the judgment of this court may be set aside by the civil judge of appeal, an officer nominated by France and the bishop of Urgel alternately; the final appeal is either to the Court of Cassation at Paris, or to the Episcopal College at Urgel. A tribute of 960 francs is paid annually to France, in return for which the Andorrans are permitted to import certain articles free of duty; the bishop of Urgel receives a tribute of almost the same amount. The expenses of government are defrayed by a species of rent paid by owners of flocks to the community for the use of the pasture land.

ANDOVER, an ancient market-town in the north-west of Hampshire, situated near the left bank of the river Anton, 63 miles from London, and 12 from Winchester. It is well built, and contains a large parish church—erected about forty years ago on the site of the old one, which existed in the time of William the Conqueror—several dissenting places of worship, various elementary schools, and a spacious town hall. It returns one member to parliament; and its corporation, which is said to date from the reign of King John, consists of a mayor, four aldermen, and twelve councillors. Andover is the centre of a large agricultural district; its weekly markets and its fairs, held three times a year, are well attended, while at Weyhill, a village about 3 miles to the west, a fair is held every October, which was formerly one of the most celebrated in England. Malting is largely carried on, and there is an extensive iron foundry near the town; but the silk manufactures, once so prosperous, are now almost extinct. The Romans had a station at Andover, and the remains of their encampment are still to be seen in the neighbourhood. Population in 1871, 5501.

Seal and Arms.

ANDOVER, a post township of Essex county, Massachusetts, U.S., pleasantly situated on the southern bank of the Merrimack river, 21 miles north of Boston. Its first settlers came from Andover in England in 1643, and purchased a part of the Indian domain known as Cochichewick from the natives for $26.64 and a cloth coat. The streams in the vicinity afford water power, which is employed to some extent in manufactures of flannels, linen, and shoe thread; but the town is chiefly known by its academic institutions. The Punchard High School has a high local reputation. Phillips Academy is one of the most popular schools in New England. It was endowed by the Phillips family in 1778 with $85.000 (£17,000) and considerable landed estates, and has always been well sustained. It has a principal and eight instructors, and the number of pupils in 1873 was 252. The Andover Theological Seminary was founded in 1807, under the auspices of the Congregationalists, but is open to Protestants of all denominations. It has five professors and generally more than 100 students. Tuition and room rent are free to all, and additional aid is given to indigent students. The Abbot Female Academy, for the education of female teachers (founded in 1829), is also a flourishing institution. Andover has a bank, four churches, and two hotels. Its population in 1870 was 4873.

ANDRADA, Diego Payva d' (born at Coimbra in 1528, died 1575), a learned Portuguese theologian, who distinguished himself at the Council of Trent, to which he was sent by king Sebastian. He wrote seven volumes of sermons, besides several other works, one of which, *De Conciliorum Auctoritate*, was much esteemed at Rome for the great extension of authority it accorded to the Pope. His *Defensio Tridentinæ Fidei*, a rare and curious work, in which he discusses, among other subjects, immaculate conception, was published posthumously (1578).

ANDRADA E SYLVA, Bonifacio Jozé d', a distinguished Brazilian statesman and naturalist, was born at Villa de Santos, near Rio Janeiro, 1765, and died at Nictheroy, 1838. In 1800 he was appointed professor of geology at Coimbra, where he had studied, and soon after inspector-general of the Portuguese mines; and, in 1812, he was made perpetual secretary of the Academy of Lisbon. Returning to Brazil in 1819, he urged Dom Pedro to resist the recall of the Lisbon court, and was appointed one of his ministers in 1821. When the independence of Brazil was declared, Andrada was made minister of the interior and of foreign affairs; and when it was established, he was again elected by the constituent Assembly, but his democratic principles resulted in his dismissal from office, July 1823. On the dissolution of the Assembly in November, he was arrested and banished to France, where he lived in exile near Bordeaux till, in 1829, he was permitted to return to Brazil. But being again arrested, in 1833, and tried for intriguing on behalf of Dom Pedro I., he passed the rest of his days in retirement. He has left no single work of any length, but a multitude of memoirs, chiefly on mines.

ANDRÉ, John, an accomplished soldier, who has gained a place in history by his unfortunate end, was born in London, in 1751, of Genevese parents. Accident brought him in 1769 to Lichfield, where, in the literary circle of Miss Anna Seward, he met Miss Honora Sneyd. A strong attachment sprung up between the two; but their marriage was disapproved of by Miss Sneyd's family, and Andre was sent to cool his love in his father's counting-house in London. Business was, however, too tame an occupation for his ambitious spirit, and in March 1771 he obtained a commission in a regiment destined for America, the theatre at that time of the war of independence. Here his conduct and acquirements gained him rapid promotion, and he became in a few years aide-de-camp to the commander-in-chief of the British forces, Sir Henry Clinton, who had so high an opinion of him, that in 1780 he raised him to the post of major and adjutant-general of the forces. While Andre was in this situation, the American general, Arnold, who had displayed much energy in the cause of the colonies, conceiving himself injuriously treated by his colleagues, made a proposition to the British to betray to them the important fortress of West-Point, on the Hudson River, the key of the American position. This seemed a favourable opportunity of concluding the war, and Major André was appointed to negotiate with Arnold. For this purpose he landed from a vessel bearing a flag of truce, and had an interview with Arnold; but before the negotiations were finished, an American fort had fired on the vessel, and forced her to drop down the river. André, therefore, could not return by the way he came, and it was necessary to pass the night within the American lines at the house of his guide, Smith, and set out next day by land for New York. Both were provided by Arnold with passports, and succeeded in passing the American outposts undetected. Next day, however, just when all danger seemed to be over, and Smith had left André in sight of the English lines, André was stopped by three militiamen of the enemy, and carried back a prisoner. Washington sent him before a court-martial, and notwithstanding a spirited defence, and the remonstrances of the British general, who did all he could to save him, Major Andre was executed at Tappan as a spy on the 2d October 1780—a sentence perhaps justified by the extreme rigour of martial law, as he had been in disguise within the lines of the enemy; but the traitor Arnold, through the address of poor Andre, escaped by timely flight the punishment he justly merited. Besides courage, and distinguished military talents, Major Andre possessed a well-cultivated mind. He was a proficient in drawing and in music, and showed considerable poetic talent in his humorous *Cow-chase*, a kind of parody on *Chevy-chase*, which appeared in three successive parts at New York, the last on the very day of his capture. One of his last letters gives an affecting incident relating to his first love. When stripped of everything by those who seized him, he contrived to retain the portrait of Miss Sneyd, which he always carried on his person, by concealing it in his mouth. He was not aware that this lady had breathed her last some months before. His unhappy fate excited universal sympathy both in America and all over Europe, and the whole British army went into mourning for him. A mural sculptured monument to the memory of Major André was erected in Westminster Abbey by the British Government, when his remains were brought over and interred there in 1821.

ANDREA, Giovanni, the most famous Italian canonist of the 14th century, was born at Mugello, near Florence, about 1275. He studied canon law at Bologna, where he distinguished himself in this subject so much that he obtained a professorship of law, first at Padua, then at Pisa, and lastly at Bologna, rapidly acquiring a high reputation for his learning and his moral character. Little is positively known of his history, though many curious stories are told regarding him—*e.g.*, that, by way of self-mortification, he lay every night for twenty years on the bare ground with only a bear's skin for a covering; that, in an audience he had with Pope Boniface VIII., his extraordinary shortness of stature led the Pope to believe he was kneeling, and to ask him three times to rise, to the immense merriment of the cardinals; and that he had a daughter, Novella, so accomplished in law as to be able to read her father's lectures in his absence, and so beautiful, that she had to read behind a curtain lest her face should distract the attention of the students. He is said to have died at Bologna of the plague in 1348, after having been a professor for forty-five years. He was buried in the church of the Dominicans, and the public estimation of his character is testified by his epitaph, in which he is styled *Rabbi Doctorum. Lux, Censor, Normaque Morum.* Andrea wrote the following works: *Gloss on the Sixth Book of the Decretals; Glosses on the Clementines; Commentary on the Rules of Sextus.* His additions to the *Speculum* of Durando are a mere adaptation from the *Consilia* of Oldradus, as is also the book *De Sponsalibus et Matrimonio*, from J. Anguisciola.

ANDREANI, Andrea, a celebrated engraver on wood, in chiaroscuro, was born at Mantua about 1540, and died at Rome in 1623. His engravings are scarce and valuable, and are chiefly copies of Mantegna, Dürer, and Titian. The most remarkable of his works are "Mercury and Ignorance," the "Deluge," "Pharaoh's host drowned in the Red Sea" (after Titian), the "Triumph of Cæsar" (after Mantegna), and "Christ retiring from the judgment-seat of Pilate."

ANDREASBERG, a town of Prussia, in the former kingdom of Hanover, situated in the Hartz mountains, at an elevation of nearly 2000 feet above the level of the sea, and at a distance of about 10 miles S.E. from Clausthal. It contains 3321 inhabitants, many of whom are employed in the manufacture of lace, thread, or matches. In the vicinity there are valuable mines of silver, iron, lead, cobalt, arsenic, and copper.

ANDREEVA, or Enderi, a town of Russia, in the district of the Caucasus, situated on the Aktash, 45 miles south of Kizliar. It once had a large trade in slaves. Population, 12,000.

ANDREOSSI, Antoine-Francois, Comte d', a very distinguished French officer, was born at Castelnaudary in Languedoc, 6th March 1761, and died at Montauban, September 1828. He was of Italian extraction, and his grandfather, Francois Andreossi, had taken part with Riquet in the construction of the Languedoc canal in 1669. At the age of twenty he became a lieutenant of artillery, and he early joined the republican party. He accompanied Bonaparte to Egypt as a *chef de brigade*, serving with great distinction, and was selected as one of Napoleon's companions on his unexpected return to Europe. Andreossi filled with honour many important offices of command during subsequent campaigns, and was appointed ambassador to London after the treaty of Amiens. When Napoleon assumed the title of Emperor, Andreossi was advanced to be inspector-general of artillery, and made a count of the empire. He was sent as ambassador to Austria, where he remained till the rupture with France in 1809; and when the fatal battle of Wagram prostrated Austria, he held the post of governor of Vienna as long as that capital was occupied by the French. He was afterwards sent by Napoleon as ambassador to Constantinople, where he conciliated the friendship of both Franks and Mahometans. In 1814 he was recalled by Louis XVIII., who sent him, however, the cross of St Louis. Andreossi now retired into private life, till the escape of his former master from Elba once again called him forth. After the battle of Waterloo he finally quitted the scene of political life, relieving the tedium of retirement by writing several scientific memoirs. He was a man of solid and extensive acquirements. While in Egypt he had contributed to the Institute of Cairo memoirs on the *Valley of Lake Natron*, and on *Lake Menzaleh*. Subsequently he published an account of the *Campaign on the Main and the Rednitz;* a memoir on the *Flow of the Black Sea into the Mediterranean;* a history of the *Canal du Midi*, known previously as the *Canal de Languedoc*, the chief share in the construction of which he claimed for his ancestor; and a memoir on the *Constantinople Water-works System.*

ANDRES, Juan (1740–1817), an erudite Jesuit, born in Valencia, and some time professor of literature in the university of Gandia. He is the author of a great number of treatises on science, music, the art of teaching the deaf and dumb, &c. But his chief work, the labour of fully twenty years, is one in 7 vols. 4to., entitled *Dell' Origine, dei Progressi, e dello Stato attuale d'ogni Letteratura*, where a great deal of information is accumulated. (See Hallam's *Lit. of Eur.* and Sismondi's *Lit. of S. Europe*, vol. i.)

ANDREW, St, the apostle, born at Bethsaida in Galilee, brother to Simon Peter. He had been a disciple of John the Baptist, and followed Jesus upon the testimony given of Him by the Baptist (John i. 35, 40, &c.) Andrew introduced his brother Simon, and they passed a day with Jesus, after which they went to the marriage in Cana (*ibid.* ii.), and then returned to their ordinary occupation. Some months after, Jesus meeting them while they were both fishing together, called them to him, and promised to make them fishers of men. Immediately they left their nets and followed him (Matt. iv. 19). Tradition assigns Scythia, Greece, and Thrace, as the scenes of St Andrew's ministry: he is said to have suffered crucifixion at Patræ in Achaia, on a cross of the form called *Crux decussata* (×), and commonly known as "St Andrew's cross." His relics, it is said, were afterwards removed from Patræ to Constantinople. An apocryphal book, bearing the title of *The Acts of Andrew*, is mentioned by Eusebius, Epiphanius, and others. It is now completely lost, and seems never to have been received except by some heretical sects, as the Encratites, Origenians, &c. This book, as well as a *Gospel of St Andrew*, was declared apocryphal by a decree of Pope Gelasius (Jones *On the Canon*, vol. i. p. 179, *et seq.*)

ANDREWES, Lancelot, D.D., Bishop of Winchester, one of the most illustrious of the prelates of England, was born in 1555 in Thames Street, Allhallows, Barking, London. His father Thomas was of the ancient family of the Suffolk Andrewes; in his later years he became master of Trinity House. Lancelot was sent while a mere child to the Coopers' Free School, Ratcliff, in the parish of Stepney. From this the youth passed to Merchant Taylors' School, then under the celebrated Richard Mulcaster. In 1571 he was entered at Pembroke College, Cambridge. He was here one of the first four scholars upon the foundation of Dr Thomas Watts, successor of the venerable Nowell. Contemporaneously he was appointed to a scholarship in Jesus College, Oxford, at the request of the founder (Dr Price), by Queen Elizabeth. In 1574–5, he took his degree of B.A.; in 1576 he was chosen to a fellowship at his college; in 1578 he proceeded M.A.; in 1580 he was ordained, and in the same year his name appears as junior treasurer: in 1581 he was senior treasurer, and on July 11, was incorporated M.A. at Oxford. On passing M.A., he was appointed catechist in his college, and read lectures upon the Decalogue, afterwards published, causing a *furor* of interest far and near, as his first quaint biographer Isaacson tells. The notes of these lectures printed in 1642 authenticate themselves; later editions have been suspiciously enlarged, and otherwise altered for the worse. The notes are historically valuable and important, inasmuch as with Bishops Jewell and Bilson, he teaches in them, that Christ is offered in a sacrament, that is, his offering is represented and a memory of his passion celebrated. Nothing can be more definite or emphatic than Andrewes' repudiation of a real external sacrifice in the bread and wine. From the university Andrewes went into the North, on the invitation of Henry Hastings, earl of Huntingdon, lord president of the North. In 1585 he is again found at Cambridge taking his degree of B.D. In 1588 he succeeded Crowley in the vicarage of St Giles, Cripplegate. Here he delivered his most penetrative and striking sermons on the *Temptation in the Wilderness*, and the *Lord's Prayer*—the former published in 1592, the latter in 1611. In a great sermon on April 10, in Easter week 1588, he most effectively, and with burning eloquence, vindicated the Protestantism of the Church of England against the Romanists. It sounds oddly to have "Mr Calvin" adduced herein and elsewhere as a new writer, with lavish praise and affection. Passing other ecclesiastical advancements, Andrewes was preferred by Grindal, at the suit of Walsingham, to the prebendal stall of St Pancras in St Paul's, London, in 1589. The prebendary had "the courage of his opinions," for Sir John Harington records that Sir Francis Walsingham, his patron, having laboured to get him to maintain certain points of ultra-Puritanism, he refused, having, as the garrulous Knight, in his *State of the Church of England* (pp. 143, 144), punningly remarks, "too much of the ἀνδρος in him to be scared with a councillor's frown, or blown aside with his breath," and accordingly answered him plainly, that "they were not only against his learning, but his conscience." On September 6, 1589, he succeeded Fulke as master of his own college of Pembroke, being at the time one of the chaplains of Archbishop Whitgift. His mastership of Pembroke was a success in every way. In 1589–90, as one of the twelve chaplains of the queen, he preached before her majesty a singularly outspoken sermon (March 4, 1590). In this year, on October 13, he preached his introductory lecture at St Paul's, upon undertaking to comment upon the first four chapters of Genesis. These form part of the *Orphan Lectures*, of the folio of 1657, than which there is no richer contribution to the theological literature of England, notwithstanding the imperfection of the notes in some cases. He was an incessant worker as well as preacher. He delighted to move among the people, and yet found time to meet with a society of antiquaries, whereof Raleigh, Sidney, Burleigh, Arundel, the Herberts, Saville, Stow, and Camden, were members. What by his often preaching, testifies Isaacson, at St Giles's, and his no less often reading in St Paul's, he became so infirm that his friends despaired of his life. His charities were lavish, and yet discriminative. The dearth of 1594 exhibits him as another Joseph in his care for the afflicted and poor of "the Israel of God." In 1595 appeared *The Lambeth Articles*, a landmark in our national church history. Andrewes adopted the doctrine of St Augustine as modified by Aquinas. Philosophically, as well as theologically, his interpretations of these deep things remain a permanent advance in theological-metaphysical thought. In 1598 he declined offers of the two bishoprics of Ely and Salisbury, his "nolo episcopari" resting on an intended alienation of the lands attached to these sees. On November 23, 1600, was preached at Whitehall his memorable sermon on Justification, around which surged a controversy that is even now unspent. The preacher maintained the evangelical view as opposed to the sacerdotal. On July 4, 1601, he was appointed dean of Westminster, and his sedulousness over the renowned school is magnified by Bishop Hacket in his *Life of Archbishop Williams*. On July 25, 1603, Andrewes assisted at the coronation of James I. In 1604 he took part in the Hampton Court Conference, and, better service, was one of the committee to whom we owe our authorised version of Holy Scripture. The dean frequently preached before the king, and his majesty's own learning, given him by George Buchanan, made him a sympathetic hearer. Many of these state sermons are memorable from their results and place in our ecclesiastical history. In 1605 he was appointed, after a third declinature, bishop of Chichester. In 1609 he published his *Tortura Torti*, in answer to Bellarmine's *Matthæus Tortus*. This work is one of many born of the gunpowder plot and related controversies. It is packed full of learning, and yet the argument moves freely. Nowhere does Andrewes' scholarship cumber him. It is as a coat of mail, strong but mobile. In this same year he was transferred from Chichester to Ely. His studiousness here was as intent as before. He again assailed Bellarmine in his *Responsio ad Apologiam*, a treatise never answered. From 1611 to 1618, Andrewes is to be traced as preacher and controversialist in season and out of season. In 1617 he attended the king to Scotland. In 1618 he was translated to the see of Winchester. In this year he proceeded to the Synod of Dort. Upon his return he became in word and deed a model bishop, while in every prominent ecclesiastical event of the period he is seen in the front, but ever walking in all beauty of modesty and benignity. His benefactions were unprecedented. His learning made him the equal and the friend of Grotius, and of the foremost contemporary scholars. His preaching was unique for its combined rhetorical splendour and scholarly richness, and yet we feel that the printed page poorly represents the preaching. His piety was that of an ancient saint, semi-ascetic and unearthly in its self-denial, but rooted in a deep and glowing love for his Lord. No shadow rests on his beautiful and holy life. He died 25th September 1626, and the leaders in church and state mourned for him as for a father. Two generations later, Richard Crashaw caught up the universal sentiment, when in his lines *Upon Bishop Andrewes' Picture before his Sermons*, he exclaims:—

> "This reverend shadow cast that setting sun,
> Whose glorious course through our horizon run,
> Left the dimme face of this dull hemisphere,
> All one great eye, all drown'd in one great teare."

It is to be regretted that the works of Bishop Andrewes have been only fragmentarily and uncritically collected and edited; but the edition of the Anglo-Catholic Series suffices to place him in the front rank of the theologians of England. (Works, as originally published, and as collected *ut supra*; Isaacson's Life in Fuller's *Abel Redivivus*; Buckeridge's *Sermon*; Russell's *Memoirs of the Life and Works* (1860), a medley of materials and discursive notes; British Museum Harleian MSS.) (A. B. G.)

ANDREWS, James Pettit, an English historian and miscellaneous writer, was the younger son of Joseph Andrews, of Shaw-house, near Newbury, Berks, where he was born in 1737. He was educated privately, and early discovered a taste for literature and the fine arts. Andrews was the author of several miscellaneous works, but his most extensive undertaking was his *History of Great Britain, connected with the Chronology of Europe, with Notes*, &c., of which, however, he lived to complete but two volumes. The first, which was published in 1794, in 4to, commences with Cæsar's invasion, and ends with the deposition and death of Richard II.; and the second, which appeared in 1795, continues the history to the accession of Edward VI. The plan of this work was new, and in some respects singular; a portion of the history of England is given on one page, and a general sketch of the contemporaneous history of Europe on the page opposite. He appears to have left off this work to prepare a continuation of Henry's *History of Britain*, which he published in 1796 in one volume 4to, and two volumes 8vo. He died at Brompton 6th August 1797.

ANDRIA, a town of Italy, in the province of Terra di Bari, situated in a plain 31 miles west of Bari. The town, which is said to derive its name from the caverns (*antra*) in the vicinity, is well built, and possesses a fine cathedral, founded in 1046 by Petro Normano, count of Trani. It has no manufactures of importance, but there is an extensive trade in almonds, which are imported in large quantities from the surrounding country. Andria was burned in 1799 by General Broussier, and in 1861 it became part of the new kingdom of Italy. Population, 34,000.

ANDRIEU, Bertrand, a celebrated engraver of medals, born, 24th November 1761, at Bordeaux. He is considered as the restorer of the art in France, which had declined after the time of Louis XIV.; and was so highly esteemed, that during the last twenty years of his life he was entrusted by the French Government with the execution of every work of importance. Many of his medals are figured in the *Medallic History of Napoleon.* He died at Paris 6th December 1822.

ANDRISCUS, a man of mean extraction, who, pretending to be the natural son of Perseus, last king of Macedonia, assumed the name of *Philip*, for which reason he was called *Pseudo-Philippus*, the False Philip. Escaping from Rome, where he was imprisoned for his pretensions, he found a sufficient number of partisans in Thrace to encourage him to assert his claim to the throne of Macedonia, and enable him to defeat the Roman prætor Juventius, who had been sent against him. His brief reign was marked by great cruelty and extortion. In 148 B.C. he was completely defeated, and was carried captive to Rome by Q. Cæcilius Metellus, for whom this triumph gained the name of Macedonicus. The victory placed Macedonia once more in the hands of the Romans, though at a cost of 25,000 men. Andriscus was put to death by order of the senate.

ANDROCLUS, a Roman slave who used to lead about the streets a lion that had forborne to injure him when turned loose upon him in the circus. The story is related, on the authority of an eye-witness, by Aulus Gellius (*Noct. Att.*, v. 14), who states that Androclus, having taken refuge from the severities of his master in a cave in Africa, a lion entered the cave and presented to him his swollen paw, from which Androclus extracted a large thorn.

ANDROMACHE, in Greek legend, was the wife of Hector (*Iliad*, vi. 395), and daughter of Eëtion, prince of Thebe in Mysia. Her father and seven brothers had fallen by the hands of Achilles, when their town was taken by him. Her mother, ransomed at a high price, was slain by Diana (*Iliad*, vi. 428). To Hector Andromache bore a son, Scamandrius or Astyanax, whose death by the Greeks she was forced to look on; and when, her husband also slain by them and Troy taken, the captives were apportioned, she fell to Neoptolemus, the son of Achilles, with whom she went to Phthia, or, as it is also said, to Epirus, and there bore him the sons Molossus, Pielus, and Pergamus. Neoptolemus having been slain by Orestes, left her to the Trojan seer Helenus, who had followed him, and who now married her, and governed the kingdom of Molossia for her sons. After the death of Helenus, Andromache returned to Asia Minor with her youngest son Pergamus, who there founded a town named after himself. The tragic poets found a favourite subject in the events of her life, and in her faithful and affectionate character as the wife of Hector. In works of art the death of Astyanax, and the farewell scene between Andromache and Hector (*Iliad*, vi. 323) were represented,—the latter, it is said, in a painting which drew tears from Portia the wife of Brutus (Plutarch, *Brut.* 23).

ANDROMEDA, in Greek legend, the daughter of Cepheus and Cassiopea, or Cassiepea, king and queen of the Æthiopians. Cassiepea having boasted herself equal in beauty to the Nereids, drew down the vengeance of Neptune, the sea god, who sent an inundation on the land, and a sea monster which destroyed man and beast. The oracle of Ammon announced that no relief would be found until the king exposed his daughter Andromeda to the monster, and accordingly she was fastened to a rock on the shore. Perseus, returning from having slain the Gorgon, found her in this position, slew the monster, set her free, and married her against the opposition of Phineus, to whom she had before been engaged. Before leaving Æthiopia she bore a son, Perses, from whom the Persian kings traced their descent, as did also the kings of Pontus and Cappadocia, who had a portrait of Perseus on their coins. Returning with her husband first to Seriphus, and finally to Argos, Andromeda bore him Alcæus, Sthenelus, and Electryon, and thus founded the dynasty of the Persides. After her death Andromeda was translated by Minerva to a constellation in the northern sky, near Perseus and Cassiopea. The tragic poets used the legend of her life, and in works of art the slaying of the monster by Perseus was represented.

ANDRONICUS I. (Comnenus), Emperor of Constantinople, son of Isaac, and grandson of Alexis I. Comnenus, was born about the beginning of the 12th century. He was endowed by nature with the most remarkable gifts both of mind and body. He was handsome and eloquent, but licentious; and at the same time active, hardy, courageous, and an excellent soldier. His early years were spent in alternate pleasure and military service. In 1141 he was taken captive by the Turks-Seljuks, and remained in their hands for a year. On being ransomed, he went to Constantinople, where was held the court of his cousin, the emperor Manuel, with whom he was a great favourite. Here the charms of his niece, the princess Eudoxia, attracted him. She became his mistress, while her sister Theodora stood in a similar relation to the emperor Manuel. In 1152, accompanied by Eudoxia, he set out for an important command in Cilicia. Failing in his principal enterprise, an attack upon Mopsuestia, he returned, but was again appointed to the command of a province. This second post he seems also to have left after a short interval, for he appeared again in Constantinople, and narrowly escaped death at the hands of the brothers of Eudoxia. About this time (1153) a conspiracy against the emperor, in which Andronicus participated, was discovered, and he was thrown into prison. There he remained for about twelve years, during which time he made repeated but unsuccessful attempts to escape. At last, in 1165, he was successful; and, after passing through many dangers, reached the court of Jaroslav, grand duke of Russia, at Kiev. While under the protection of the grand duke, Andronicus brought about an alliance between him and the emperor Manuel, and so restored himself to the emperor's favour. With a Russian army he joined Manuel in the invasion of Hungary, and assisted at the siege of Semlin. After a successful campaign, they returned together to Constantinople; but a year after (1167), Andronicus refused to take the oath of allegiance to the prince of Hungary, whom Manuel desired to become his successor. He was removed from court, but received the province of Cilicia. Being still under the displeasure of the emperor, Andronicus fled to the court of Raymond, prince of Antioch. While residing here he captivated and seduced the beautiful daughter of the prince, Philippa, sister of the empress Maria. The anger of the emperor was again roused by this dishonour, and Andronicus was compelled to fly. He took refuge with Amaury, king of Jerusalem, whose favour he gained, and who invested him with the town of Berytus, now Beirout. In Jerusalem he saw Theodora, the beautiful widow of the late king Baldwin, and niece of the emperor Manuel. Although Andronicus was at that time fifty-six years old, age had not diminished his charms, and Theodora became the next victim of his artful seduction. To avoid the vengeance of the emperor, she fled with him to the court of the sultan of Damascus; but not deeming themselves safe there, they continued their perilous journey through Persia and Turkestan, round the Caspian Sea and across Mount Caucasus, until at length they settled among the Turks on the borders of Trebizond. Into that province Andronicus, with a body of adventurers, made frequent and successful incursions. While he was absent upon one of them, his castle was surprised by the governor of Trebizond, and Theodora with her two children were captured and sent to Constantinople. To obtain their release Andronicus made abject submission to the emperor; and, appearing in chains before him, implored pardon. This he obtained, and was allowed to retire with Theodora into banishment in the little town of Œnoe, on the shores of the Black Sea. In 1180 the emperor Manuel died, and was succeeded by his son Alexis II., a youth of twelve or fourteen years, who was under the guardianship of the empress Maria. Her conduct excited popular indignation; and the consequent disorders, amounting almost to civil war, gave an opportunity to the ambition of Andronicus. He left his retirement, secured the support of the army, and marched upon Constantinople. Alexis was compelled to acknowlege him as colleague in the empire. The empress was put to death, and her son soon shared the same fate. His dead body is said to have been insulted by Andronicus, but the authorities for this and similar stories are in all probability prejudiced. Andronicus, now (1183) sole emperor, married Agnes, widow of Alexis II., a child eleven years of age. His short reign was characterised by strong and wise measures. He resolved to check many abuses, but, above all things, to limit the power of the nobles. The people, who felt the severity of his laws, at the same time acknowledged their justice, and found themselves protected from the rapacity of their superiors. The aristocrats, however, were infuriated against him, and summoned to their aid William of Sicily. This prince landed in Epirus with a strong force, and marched as far as Thessalonica, which he took and destroyed; but he was shortly afterwards defeated, and compelled to return to Sicily. Andronicus seems then to have resolved to exterminate the aristocracy, and his plans were nearly crowned with success. But in 1185, during his absence from the capital, his lieutenant ordered the arrest and execution of Isaac Angelus, a descendant of the first Alexis. Isaac escaped, and took refuge in the church of St Sophia. He appealed to the populace, and a tumult arose which spread rapidly over the whole city. When Andronicus arrived he found that his power was overthrown, and that Isaac had been proclaimed emperor. His offers of a general pardon, and even of abdication in favour of his son, were rejected; and, after an unsuccessful attempt at escape, he was seized and dragged before the new emperor. Isaac delivered him over to his enemies, and for three days he was exposed to their fury and resentment. At last they hung him up by the feet between two pillars. His dying agonies were shortened by an Italian soldier, who mercifully plunged a sword into his body. He died on the 12th September 1185.

ANDRONICUS II. (Palæologus), Emperor, was born 1260. He was the elder son of Michael Palæologus, whom he succeeded in 1283. During his reign the Turks under Osman conquered nearly the whole of Bithynia; and to resist them the emperor called in the aid of Roger de Flor, who commanded a body of adventurers. The Turks were defeated, but Roger was found to be nearly as formidable an enemy to the imperial power. He was assassinated in 1308. His adventurers declared war upon Andronicus, and after devastating Thrace and Macedonia, settled in the southern part of Greece. From 1320 onwards the emperor was engaged in war with his grandson, Andronicus, in whose favour he was compelled to abdicate, 1328. He retired to a convent, and died about 1334.

ANDRONICUS III., grandson of the preceding, was born about 1296. His conduct during youth was so violent, that his grandfather resolved to deprive him of his right to the crown. Andronicus rebelled, and in 1328 compelled his grandfather to abdicate in his favour. During his reign he was engaged in constant war, chiefly with the Turks, who greatly extended their conquests. He died in 1341.

ANDRONICUS of Cyrrhus, a Greek astronomer, about B.C. 100, built at Athens an octagon tower, with figures carved on each side, representing the eight principal winds. A brazen Triton at the summit, with a rod in his hand, turned round by the wind, pointed to the quarter from which it blew. From this model is derived the custom of placing weathercocks on steeples. A considerable portion of this tower still exists; and, instead of "tower of the winds," it should be called *horologium*, the name by which it is designated by Varro.

ANDRONICUS of Rhodes, the eleventh scholarch of the Peripatetics, lived about B.C. 70. His chief work was the arrangement of the writings of Aristotle, the materials for which had been supplied to him by Tyrannion. Besides arranging the works, he seems to have written paraphrases and commentaries, none of which have come down to us. Two writings under the name Andronicus are sometimes erroneously attributed to him, one on the Emotions, the other a commentary on Aristotle's *Ethics*.

ANDROS, or Andro, the ancient *Andros*, an island of the Grecian Archipelago, the most northerly of the Cyclades, lying 6 miles S.W of Eubœa, and about 2 N. of Tenos. It is nearly 25 miles long, and its greatest breadth is 10 miles. Its surface is for the most part mountainous, with many fruitful and well-watered valleys, which produce vines, grain, olives, pomegranates, lemons, figs, and oranges, and supply food for cattle, silk-worms, and bees. At Andros, the capital, a town on the east coast, containing about 5000 inhabitants, there are silk and carpet manufactures, the former of which gives rise to a considerable export trade; but the harbour does not afford accommodation except for vessels of small size, and is much inferior to that of Gaurio (*Gaurium*) on the west coast, near the ruins of an older Andros, the ancient capital of the island. This Andros, which was situated on the brow of a hill that commands the whole coast, contained a famous temple, dedicated to Bacchus, and a spring that was said to flow with wine during the feast of the god. The island is supposed to contain about 15,000 inhabitants, the bulk of whom belong to the Greek Church. According to the ordinary account, Andros, which is said to derive its name either from Andreus, a general of Rhadamanthus, or from a seer called Andrus, was colonised by the Ionians about 1000 B.C., and soon became a place of some importance. In 480, after the battle of Salamis, Themistocles made an attempt to take the capital, wishing to punish the inhabitants for their readiness to assist the Persians in their invasion of Greece; and, although he failed in this enterprise, the island afterwards became for a time subject to the Athenians. In 333 it was added to the Macedonian empire; and after the death of Alexander the Great, became part of Ptolemy's kingdom. In 200 it was taken by the Romans, who handed it over to Attalus I., king of Pergamos; and in 133 it reverted to the Romans, in accordance with the will of Attalus III. On the dissolution of the empire of the East, Andros came under the rule of the Turks; but now, along with the island of Tenos, it forms a government of the modern kingdom of Greece.

ANDUJAR, a town of Spain, in the province of Jaen, Andalusia, situated near the Guadalquivir, 20 miles N.W. of Jaen. It is a dull, unhealthy place, possessing few buildings of any architectural beauty; but there is a road leading to an old bridge over the Guadalquivir which is lined with fine trees. The town has an inconsiderable trade in cattle, grain, oil, and fruit. It is most widely known for its porous earthenware jars, called *alcarrazas*, which possess the property of keeping water cool in the hottest weather, and which are manufactured in great numbers from a whitish clay found in the neighbourhood. The Convention of Baylen was signed at Andujar in 1808; and the decree of the duke of Angoulême, by which all Spanish authorities were subordinated to the French, was published in the same town in 1823. Population, 14,096.

ANDUZE, a town of France, in the department of Gard, situated on the Gardon d'Anduze, about 6 miles S.W. of Alais. It possesses considerable manufactures of serges, stockings, hats, silk, and leather, and has 5303 inhabitants, many of whom are Protestants.

ANECDOTE, a word derived from α privative and ἐκδίδωμι, to give out or publish, means originally something not published. It has two distinct significations. First, the primary one is something not published, in which sense it has been used to denote either secret histories,—Procopius, *e.g.*, gives this as one of the titles of his secret history of Justinian's court,—or portions of ancient writers which have remained long in manuscript and are edited for the first time. Of such *anecdota* there are many collections; the earliest was probably Muratori's, in 1709. Besides it, there are *anecdota* by Bekker, Bachmann, Cramer, Boissonade, Matranga, Miller, Wolff, Villoisin, Amaduci, Tischendorf, and, the most recent, Val. Rose, 1864–71. There are also *anecdota* of more modern writers; some of these are given by Martene and Durand, *Thesaurus Novus Anecdotorum* (1717), and Pez, *Thesaurus Anecdotorum Novissimus* (1721). Second, in the popular acceptation of the word, which is to be traced to their being, in the first instance, colloquial, anecdotes are relations of detached interesting particulars. Of such anecdotes the collections are almost infinite; the best in many respects is that compiled by Byerley and Clinton Robertson, known as the *Percy Anecdotes* (1820–23).

ANEL, Dominique, an eminent French surgeon, born at Toulouse in 1679. He is celebrated for his successful treatment of aneurism and *fistula lachrymalis*, and was the inventor of the probe and syringe still known by his name. He wrote several medical works, published at Amsterdam 1707, Turin 1713, and Paris 1822. He died about 1730.

ANEMOMETER, or *wind-measurer* (from ἄνεμος, wind, and μέτρον, a measure), a contrivance for indicating the rate and direction of the wind. Ever since the birth of true experimental science, it has been recognised as a matter of great importance and interest to man that he should know something of the laws according to which the atmospheric currents and changes are produced. Among meteorological phenomena, none deserve more attention than the elements of the wind; and none have received more. Yet anemometry has been all along the least successful department of meteorology, partly owing, of course, to the nature of the agent to be dealt with, which is the very type of fluctuation, and partly to a mistaken path of observation that was too long followed. The error which, from the days of Hooke, in the middle of the 17th century, to within a comparatively recent period, misdirected the efforts of inventors, was the idea that the elements to be determined in the case of the wind are its direction and *pressure*, whereas practically they are its direction and *velocity*. If the currents of air were anything like uniform, it would be a comparatively simple matter to deduce the velocity from the pressure; but their variability is so very great, that the relations between the velocity and the pressure become unworkably complex. We know, from the elementary principles of dynamics, that the pressure at any instant will vary as the square of the velocity. Obviously, therefore, the relative variations of the pressure will be *twice as great* as those of the velocity; and the latter are too great, as we find them, to encourage us to double them artificially. It must also be remembered that, from the inertia of the indicating apparatus, errors will in every case arise; and these also will be doubled if we take the pressure instead of the velocity variations. From all this it will appear that comparatively little importance is to be attached to the earlier and to all statical modes of anemometry.

The essentials of every anemometer are two: (1), a *wind-vane*, to show changes of direction; and (2), a *wind-gauge*, to show changes of velocity, or of force. There is also a distinction which we may have in every kind of meter. They may be either *non-recording*, as merely exhibiting the variations to the eye; or *recording*, or marking them permanently on paper.

The wind-vane, or weather-cock, is simply a flat sheet of thin metal, or two sheets in the shape of a thin wedge, at the end of a metal rod, the whole turning freely on a vertical axle. Besides serving to show the direction of the wind itself, the vane is often used to turn the gauge, so as to present the pressure-surface with its face always direct to the wind.

Of all the gauges that have been invented or proposed it would be impossible to give even the names. The primitive statical forms of anemometer—that is, such as set against the force of the wind a gradually increasing resistance, with some means of indicating the point of balance—have been divided by Dr Robinson (*Trans. Roy. Irish Acad.*, vol. xxii. p. 150) into three classes:—First, vertical windmills, kept facing the wind by a vane, and acting by winding on their axle a string against some form of graduated resistance. Of this nature were Dr Hooke's anemometer (which is generally considered the first practical attempt in wind-measuring), and those of Wolfius and Martin. The second class consists of those in which the wind acts on a flat plate, usually a foot square, pressing it against the elasticity either of a metallic spring or of a mass of confined air, a previous graduation of the elastic force having been made for each instrument. The first gauge of this type was invented by the celebrated Bouguer about the middle of last century; and since his time there have been many attempts at improvement of this principle, the apparent simplicity of the spring-measure being its recommendation. Modified forms of Bouguer's wind-pressure gauge are in use even at the present day; and about a quarter of a century ago a self-registering adaptation of it was constructed by Osler, and very generally employed. The third class measures the wind-force by the difference of level it is capable of producing in an inverted syphon, or U tube, containing water or some other liquid. Lind's anemometer, invented in 1775, is the best known of this type, and is still in common use. It is simply a U tube, with one leg bent at right angles towards the upper end, and attached to a vane, so as to have its mouth constantly facing the wind. It is about half-filled with water, and a scale graduated to hundredths of an inch is attached. The difference of level in the legs of the syphon indicates the force of the wind; but it is only by experiment that the pressures corresponding to these differences can be laid down. Thus each instrument requires a carefully-constructed reference table of pressures and velocities corresponding to its readings. According to Lind, a difference of level of 1 inch indicates a pressure of 5·2 lb on the square foot, and that corresponds to a velocity of about 32½ miles an hour, which is in common language a *high wind*. A difference of 3 inches would indicate a *storm*, and one of 6 inches a *hurricane.* Rivalling this in simplicity is a fourth class, that may be added to Dr Robinson's, viz., *pendulum anemometers*, where the pressure-plate is swung as a pendulum, and indicates the wind-force by its deviation from the vertical. The first of this form was invented by the Marquis Poleni, and gained the prize of the French Academy in 1733. They are still employed as simple rough-and-ready indicators to the eye of the strength of the wind.

Several other anemometers have been contrived, which, from being essentially non-recording, may be mentioned as more curious than valuable. Among these are—(1.) A *musical anemometer*, suggested by Dr Hooke, and constructed by Delamanon, in which the wind was caused to sound automatically, in a set of pipes, a particular note corresponding to its velocity; (2.) *Leslie's anemometer*, or rather anemometric principle, which deduces the velocity of the wind from its effect in cooling a thermometer, it being supposed that the rate of cooling is proportional to the velocity of the wind; (3.) *Brewster's evaporation anemometer*, by which the velocity may be deduced from the amount of water evaporated in a given time from a rough open surface, such as sponge or flannel, the two being in proportion.

Osler's anemometer, the last of the pressure-gauges we shall mention, being one of the most trustworthy and most common registering anemometers in this country, merits a more particular description. It traces with pencils on a sheet of paper (which is moved along, either in a vertical or a horizontal position, at a constant rate by means of clock-work) lines which indicate changes of the wind, both in direction and in pressure. Its general principle will be readily understood without a diagram. Changes of *direction* are recorded in this way. The axle that carries the vane, and turns with it, has keyed on its lower end a pinion which, working in a horizontal rack, moves it backwards or forwards as the axle turns one way or the other; and a pencil fixed to the rack traces its movements on the register-sheet. Changes of *pressure*, or *wind-force*, are measured by means of springs. A square foot of a light metal plate, placed vertically and turning with the vane-rod, receives the impulse of the wind, and is forced against three springs, so arranged that one, two, or all of them may be pressed on according to the violence of the wind. The extent of compression against the springs is transmitted through the hollow vane-axle, by means of chains and pulleys, to a light spring, which presses a pencil gently against the paper. Variations of motion of the upper plate thus correspond to definite lateral deviations of this second spring pencil, and a wavy line is traced on the paper as it moves along. The register-sheet is ruled across its length into twenty-four equal parts, one of which passes the pencil points each hour; and lengthways it is ruled—first, with lines corresponding to the cardinal points, under the direction-pencil; and secondly, on the field of the other pencil, with lines spaced by actual experiment so as to correspond to gradations of 5, 10, 15, 20, &c. lb of wind-pressure on the square foot. Thus the pressure-curve, in the same way as on the indicator of a steam-engine, includes between it and the horizontal line of zero-pressure a space proportional to the amount of *work done* by the wind on the upper pressure-plate. Of course, so long as the wind blows in one direction, the direction-pencil traces a horizontal line; and if there be no wind at all, both pencils trace the zero horizontal lines.

We have not space to enter particularly into the history of the direct velocity-measuring anemometers. As long ago as 1783, one was contrived on this principle by Mr Edgeworth for the measurement of air-currents; but to Dr Whewell belongs the credit of first appreciating at its true value the velocity as opposed to the pressure measure. In the *Cam. Trans.*, vol. vi., he describes an instrument of his own devising, which was afterwards extensively used. Sir W. Snow Harris recommended it strongly to the British Association in 1844, exhibiting results of his own observations with it during three previous years. Owing, however, to some practical defects, such as the great frictional resistance of toothed wheels and endless screws, which have more effect on the indications of a gentle wind than of a high one, and to the want of an arrangement for indicating the *times* of the variations, Dr Whewell's instrument has now fallen into disuse. A description of it may be found in Drew's *Practical Meteorology*. One of the most valuable contributions to this science was made by Dr Robinson, of Armagh, who between the years 1843 and 1846 conducted a number of experiments and calculations on the proper form to be given to the revolving vanes. He found radical defects in the principle of all the vanes previously employed; either their moving power was not sufficiently great to make the frictional correction inconsiderable, or their velocity, in place of being less, was often three or four times greater than that of the wind, requiring greater complicacy of machinery to reduce the speed of the tracing point; or, lastly, their results were not identical, though constructed after the same type. The form adopted by Robinson to remedy these defects is that shown in the figure. Though it had been suggested to him by Edgeworth, it deservedly bears the name of *Robinson's Cups* (fig. 1), as he was the first to show experimentally and analytically its advantages. The arrangement consisted of four light metal hemispheres C, of as large a diameter as convenient, extended at the ends of light and strong metal radii, so that they shall be as far from the axis of motion as possible, and so reduce the effect of friction to a minimum. They require no vane to keep them facing the wind, that represented by F, F, in the figure having a movement quite independent of the cups, as will be explained presently. He found that the cups move at almost exactly one-third of the rate of the wind—a happy simplicity of ratio—and this for all instruments made after one type. Experiments were made with sets of two, three, four, and six cups; but the velocity ratio between the cups and the wind was simplest and most constant with four, the number now universally employed. In the paper already quoted (*Trans. Roy. Irish Acad.*, vol. xxii.), Dr Robinson describes a self-registering apparatus, to which he had fitted the horizontal cups. But we shall describe instead one of the more modern and simple registers, which seems to leave little further to be desired in the way of compactness and accuracy. It is the invention of Mr Beckley, of the Kew Observatory, and is described in full in the *Report of the British Association*, 1858, p. 306. The outside, or wind-receiving parts are represented in the above figure, and consist of Robinson's cups C, for the wind-velocity, and a double fan F, or windmill governor, for wind-direction. The fans serve as a vane, turning so as to keep their axes constantly at right angles to the wind, and are more steady than the ordinary vane. They are connected with the outer brass tube B, and carry it round with them on any change of wind-direction. The second figure shows the manner in which the motions of the fans and cups are recorded. R is a cylinder, which carries the register-sheet, on which the

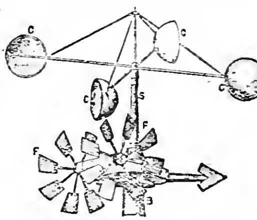

FIG. 1.—Cups and Vane of Anemometer.

two pencils P, Q, press lightly. It is turned round at a uniform rate by clock-work in K, making a complete revolution in twenty-four hours, or moving through half an inch per hour. Horizontal lines divide the sheet into hour spaces, marked 1, 2, 3, &c., in the figure. The fan, or direction-axle B (fig. 1), communicates its motions to a mitre wheel M (fig. 2), which, gearing into the bevel wheel T, moves the cylinder D, with its brass pencil P. By a change of the wind from north to south, the pencil would trace a line along the cylinder between the vertical lines N and S. In like manner the velocity of the cups is communicated by a shaft passing through the direction-axle to a mitre wheel W, which moves the bevel wheel N, the cylinder L, and its pencil Q. Vertical lines are drawn on the paper, so that the pencil moves over one space, while the wind travels 10 miles, or the cups

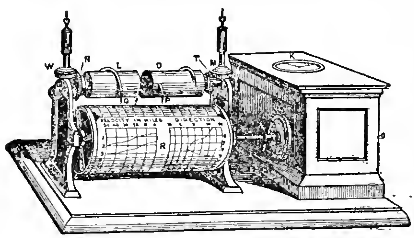

Fig. 2.—Recording Apparatus.

one-third of that distance. The velocity range does not extend beyond 50 miles, that being sufficiently high above the *average* rate of the winds. The sheet requires to be renewed, and the clock-work rewound every twenty-four hours, a matter of only a minute or two. The figure shows a simple brass spiral pencil; but the pencil devised by Beckley for the Kew Observatory consists of a strip of brass fixed spirally on edge, so that for equal increments of rotation of its cylinder its point of contact with the register-sheet shifts along by equal increments horizontally.

Anemometry now forms a most important feature in all meteorological observations, and many important and remarkable results have appeared since the invention of self-recording apparatus. See Meteorology.

ANET, a town of France, in the department of Eure-et-Loir, situated between the rivers Eure and Vègre, 9 miles N.E. of Dreux. It contains the ruins of a magnificent castle, built by Henry II. for Diana of Poitiers, and near it is the plain of Ivry, where Henry IV. defeated the armies of the League in 1590. It has 1418 inhabitants, who carry on a small trade in corn, wood, and fodder.

ANEURISM (from ἀνεύρυσμα, a dilatation), a cavity, which contains blood, either fluid or coagulated, and which communicates with an artery; the walls of the cavity are formed either of the dilated artery or of the tissues around the vessel. This affection, a malady of middle life and old age, may arise in consequence of injury or disease of the blood-vessels.

ANGARA, Upper and Lower, two rivers of Asiatic Russia, in the government of Irkutsk. The former rises in the mountains to the east of Lake Baikal, and falls into the head of the lake after a course of nearly 300 miles. The latter, which is sometimes called the Upper Tungonska, flows out of Lake Baikal, near its southern extremity, and passing the town of Irkutsk, falls into the Yenisei, after a course of about 1100 miles. The current of the river is very strong, forming several rapids in its progress. The scenery on its banks is frequently extremely beautiful.

ANGARIA (ἀγγαρεία), a sort of government postal system adopted by the Romans under the empire, borrowed from the ancient Persians, among whom, according to Xenophon, it was established by Cyrus. Couriers (*angari*, ἄγγαροι) on horseback were posted (*positi*), at certain stages along the chief roads of the empire, for the transmission of royal despatches by night and day in all weathers. The supply of horses and their maintenance were compulsory, constituting under the Romans a burden from which the emperor alone could grant exemption. Hence the word came to mean generally compulsory service in the despatch of royal messages.

ANGEL is a transcription of the Greek ἄγγελος, *a messenger*, but in signification corresponds to the special theological sense which the latter word assumed among the Hellenistic Jews (and hence in the New Testament and in Christian writings), by being adopted as the translation of the Hebrew *Mal'akh.* Thus both name and notion of angel go back to the Old Testament.

The Old Testament belief in angels has two sides, being, on the one hand, a particular development of the belief in special manifestations of God to man; and on the other hand, a belief in the existence of superhuman beings standing in a peculiar relation of nearness to God. These two sides of the doctrine are historically associated and co-operate in the later developments of Biblical angelology, but are not in all parts of the Old Testament fused into perfect unity of thought.

The first side of the belief in angels is expressed in the word *Mal'akh*, a messenger or ambassador,—more fully, *messenger of Jehovah* [*E. V.*, angel of the Lord], *messenger of God.* The whole Old Testament revelation moves in the paradox that God is invisible and inaccessible to man, and yet approaches man in unmistakable self-manifestation. This manifestation takes place in various ways,—in the priestly oracle, in prophecy, in the glory of God within the sanctuary [shekhina]. But in particular the early history represents God as manifesting himself by his *messenger.* In special crises "the messenger of Jehovah" calls from heaven to Hagar or to Abraham (Gen. xxi., xxii.) Or if God seeks to commune more fully with a man, his messenger appears and speaks to him. The narratives of such angelophanies vary in detail. Generally there is but one angel, but Abraham is visited by three (Gen. xviii.) Sometimes the dignity of the heavenly visitor is detected while he is present, at other times he is mistaken for a prophet, and recognised only by something supernatural in his disappearance (Judges vi. 21, *f.*, xiii. 20). Jacob wrestles all night with a "man," who at length with a touch dislocates his thigh (Gen. xxxii. 24, *ff.*) At other times no human form is seen. It is the angel of Jehovah who speaks to Moses in the burning bush, and leads the Israelites in the pillar of cloud and smoke (Exod. iii. 2, xiv. 19).

In all this there is perfect indifference to the personality of the angel, who displays no individuality of character, refuses to give a name (Gen. xxxii.; Judges xiii.), acts simply as the mouthpiece of God. This is carried so far that in his mouth the pronoun *I* indicates Jehovah himself; while the narrative passes, without change of sense, from the statement, "the angel of Jehovah appeared; spoke," &c., to "Jehovah appeared, spoke." (*Cf.*, for example, Exod. iii. ver. 2 with ver. 4; xiii. 21, with xiv. 19.) Those who see the angel say they have seen God (Judges xiii. 22; Gen. xxxii. 30). The angelophany is a theophany as direct as is possible to man. The idea of a full representation of God to man, in all his revealed character, by means of an angel, comes out most clearly for the angel that leads Israel in the very old passage, Exod. xxiii. 20, *ff.* This angel is sent before the people to keep them in the way and bring them to Canaan. He speaks with divine authority, and enforces his commands by divine sanctions, "for my name [*i.e.*, the compass of my revealed qualities] is in him." The question naturally arises, how the angel who possesses these high predicates stands related to angels who elsewhere appear not representing the whole self-manifestation of God to his people, but discharging isolated commissions. The Biblical data for the solution of this question are very scanty. An essential distinction between the "angel of the Lord," who speaks in all things with full divine authority, and subordinate angels, is sought mainly in Gen. xviii. and in Exod. xxxii. 30, *ff.*, xxxiii. compared with Isaiah lxiii. 9. In the former case, though two of the three angels leave Abraham, Jehovah goes his way only on the departure of the third. Yet the two angels when they come to Lot are apparently as direct a manifestation of God to him as the third was to Abraham (xix. 18, *ff.*) And in the other passage it has not been clearly made out that there is really a distinction drawn between an angel who represents God's presence and an angel of a lower kind who does not do so. The notion (long current in dogmatic theology, and which goes back to the earliest controversies between Jews and Christians) that "the angel of the Lord," as contradistinguished from created angels, is the Logos—the second person of the Trinity—has found defenders down to the present day (Hengstenberg, Keil, &c.), but certainly does not express the sense of the Old Testament writers. And it seems equally unprofitable to base on such passages as we have cited, a controversy whether "the angel of Jehovah" is one special angel charged throughout history with special functions towards the covenant people, or is any angel who from time to time has a special commission, or is to be viewed, at least in some cases, not as a hypostatic being, but simply as a momentary sinking of the invisible God into the sphere of visibility. The *function* of the angel so entirely overshadows his *personality*, that the Old Testament does not ask who or what this angel is, but what he does. And the answer to this last question is, that he represents God to man so directly and fully, that when he speaks or acts God himself is felt to speak or act. The strongest passage perhaps is Gen. xlviii. 15, *f.*

The disposition to look away from the personality of the angels and concentrate attention on their ministry, runs more or less through the whole Old Testament angelology. It is indeed certain,—to pass to the second side of the doctrine,—that the angelic figures of the Bible narrative are not mere allegories of divine providence, but were regarded as possessing a certain superhuman reality. But this reality is matter of assumption rather than of direct teaching. Nowhere do we find a clear statement as to the creation of the angels [Gen. ii. 1 is ambiguous, and it is scarcely legitimate in Psalm cxlviii. to connect ver. 2 with ver. 5]. That they are endowed with special goodness and insight, analogous to human qualities, appears as a popular assumption, not as a doctrine of revelation (1 Sam. xxix. 9; 2 Sam. xiv. 17, xix. 27). Most characteristic for the nature of the angels is the poetical title "sons of God" (*Bnê Elohim*, or, with a slight modification, *Bnê Elim*, in English version incorrectly "mighty," "sons of the mighty," Ps. xxix. 1, lxxxix. 6), which, in accordance with the idiomatic force of the word *sons*, may be paraphrased, "Beings who in a subordinate way share something of divine majesty." Perhaps in Psalm lxxxii. the name Elohim itself varies with the more usual "sons of Elohim."

Taken collectively, the angels form the hosts of Jehovah (Ps. ciii. 21, &c.), or the host of heaven (1 Kings xxii. 19), names correlative to the new title of God which springs up at the close of the period of the Judges, "Jehovah [God of] hosts." The notion of angels as divine armies is not like that of the individual "messenger" closely connected with the theophanic history (yet compare Gen. xxxii. 1, 2; Joshua v. 13, *sqq.*), but belongs rather to the delineation of the majesty of God in poetry and prophecy. As the whole conception of the heavenly palace and throne is obviously symbolical, we must allow for conscious poetic art when the angels are represented surrounding God's throne in the form of an *assembly* or *privy council* of holy ones (consecrated servants), praising his name, or receiving his commands, and reporting their execution (Ps. xxix., lxxxix. 6–8; 1 Kings xxii. 19, *ff.*; Job i.) Similarly much must be allowed for the free play of fancy when in the last judgment against the enemies of his people, Jehovah descends to battle with his *heroes* (Joel iv. 11), his *holy ones* (Zech. xiv. 5), or when he triumphantly enters Zion amidst myriads of heavenly war chariots (Ps. lxviii. 17). Compare Isa. lxvi. 15, Hab. iii., which show how closely such imagery is connected with the physical phenomena of the thunderstorm.

With the development of the idea of countless hosts of divine ministers is naturally associated, in place of the old angelic theophany, the conception of an invisible agency of angels, who are henceforth seen only in vision or to eyes specially opened (Num. xxii. 31; 2 Kings vi. 17). To the guidance of Israel by the angel of Jehovah succeeds the belief in angelic guidance of individuals (Ps. xxxiv. 7), more or less poetically worked out (Ps. xci. 11). Conversely, pestilence and other judgments are angelic visitations (2 Sam. xxiv.; 2 Kings xix. 35; Ps. lxxviii. 49, where the "evil angels" of the English version are not wicked angels, but angels of evil). At length this is carried so far that all natural forces that serve God are viewed as his messengers, Ps. civ. 4: "He makes winds his messengers, flaming fire his ministers." This passage clearly shows the elasticity of the whole conception. Similar is the way in which the stars, which share with the angels the name "host of heaven," appear associated with the latter (Job xxxviii. 7). Hence the later elemental angels.

Angelic interpretation between God and man reappears in Job xxxiii. 23 (*cf.* iv. 13, *ff.*), and converse with angels forms a large part of the visionary setting of the later prophetical books (Ezekiel, Zechariah). But these visions, to which the prophets do not ascribe objective reality, illustrate rather the religious imagination than the theology of the period.

The idea of ranks and classes of angels, though naturally suggested by the conception of a host (*cf.* Joshua v. 13, *sqq.*), was up to this time undeveloped; for neither the purely symbolical cherubim, nor the unique and obscure seraphim of Isaiah vi., have in the Old Testament the meaning later conferred on them of distinct classes of angels. But the angels of Zechariah present something of a systematic scheme, though it seems unsafe, with Ewald and others, to see in the seven eyes of Jehovah (iii. 9, iv. 10) a developed doctrine of seven chief angels (as in Tobit xii. 15; Rev. viii. 2), parallel to and influenced by the *Amesha-çpentas* of the Eranian mythology. The book of Daniel shows a much fuller development in a similar line. Israel, Persia, &c., have special angels (princes), whose contests represent those of human history (chaps. x., xii., *cf.* Isa. xxiv. 21, *f.*) "The great prince who presides over" Israel is named Michael (who is like God?), and the *angelus interpres* is called Gabriel (man of God). The analogy of these notions to those of Zarathustrism is less decided than has often been supposed; but the freedom which Old Testament writers allow themselves in matters of imaginative representation, to which these conceptions mainly belong, is such as to render foreign influence quite credible.

The ranks, classes, and names of angels are a favourite topic of post-canonical, and especially of Apocalyptic literature. In the book of Enoch, cherubim, seraphim, and even the wheels of Ezekiel's vision, become distinct classes of angels; and Rafael (*cf.* Tobit xii. 5), Phanuel, Uriel, &c., are added to the names of individual archangels. Specially celebrated is the interpretation which this book gives of Gen. vi. 2, where the sons of God are understood as angels. This interpretation seems to have influenced Jude, ver. 6 (*cf.* 2 Pet. ii. 4), was current in the early church as well as in Judaism, and (though the narrative so understood is quite unique in the circle of Biblical ideas) is defended on philological grounds by the best recent scholars, the occurrence being viewed as history or as myth according as the interpreter is theosophically or critically inclined. Of other passages in later Jewish literature it may suffice to refer to the full account of the creation of angels of various functions, presiding over various powers of nature, in the *Book of Jubilees* (*cf.* Rœnsch, *Das Buch der Jubiläen*, p. 259).

The angelology of the New Testament attaches closely to the notions already developed. The ministry of angels is, as in the Old Testament, specially connected with the work of salvation (Heb. i. 14), and with the person of Christ (John i. 51), to whom after the temptation (and at Gethsemane?) angels minister, and who can at will command their aid (Mat. xxvi. 53). As in the later Old Testament books, revelations by angels are given in vision or dream, but even waking eyes see the angel or angels who minister at the resurrection. So an angel delivers Peter (Acts xii.), &c. As in the Old Testament, the figure of angels is human, their raiment white, and their aspect luminous. A multitude of angels appear singing praises at the nativity (Luke ii. 13), and in general they sympathise with the repentance of sinners and the progress of the divine kingdom (Luke xv. 10; 1 Pet. i. 12). Gabriel reappears in Luke i. The belief in special guardian angels of individuals appears as current (Acts xii. 15), but the words of Jesus (Mat. xviii. 10) hardly go farther than the statements of the Psalms. The angelic hosts of the prophetic eschatology are naturally transferred to the second coming (Parusia) of our Lord. The saints after the resurrection are like the angels (Mat. xxii. 30; Luke xx. 36). In the Apocalypse angels play a great part. Notable features, in addition to the seven highest angels (viii. 2), are the angels of the seven churches (who, however, are by many taken as human figures, church officers), and the association of special angels with cosmical forces, *e.g.*, angels of fire and water (xvi. 5, xiv. 18). The same idea appears even more sharply expressed in the writings of Paul, if, as Ritschl has rendered plausible, the elements (elemental powers) of the world (Col. ii.; Gal. iv. 3) are the angels, and specially the angels of the law. This view is connected with the characteristic position of Paul and the Epistle to the Hebrews, that the inferiority of the old covenant is stamped by the fact that the law was given and enforced by angels (Gal. iii., iv.; Heb. ii.; *cf.* Acts vii. 53), an idea partly based on Exod. xxiii. 20, *f.*, and partly on a transference to Sinai of the usual poetico-prophetic imagery of a theophany—a transference suggested by Ps. lxviii. 17, Deut. xxxiii. 2, and actually carried out in the LXX. translation of the latter text, and in the current Jewish theology of the period. Angel worship is condemned in Col. ii. (probably with reference to Essene doctrine); *cf.* Rev. xix. 10. In Heb. ii., and 1 Cor. vi. 3, Christians are superior to angels.

Theological reflection on the doctrine of angels already begins among the Alexandrian Jews; and Philo, who calls them "a chorus of unembodied souls" occupying the air, places them in close parallelism to his speculations on the divine *ideas* or *powers*. From this association the transition is easy to Gnostic speculations, where the ranks of angels appear as produced by successive emanation, and thus serve to fill up the interval which Gnosticism puts between God and the world. In this connection we find also a doctrine of creation by angels (Basilides), and dualistic views of good and evil angels. Against these heresies the early church emphasises the creation of angels and the fall of the evil angels, but Origen tells us that up to his time the ecclesiastical doctrine did not define "quando isti creati sint vel quales aut quomodo sint." On these topics, however, many subtle questions arose, *e.g.*, whether angels have bodies of an ethereal kind, whether they were created before the world or along with the light, &c. Gradually angel-worship sprung up, and in spite of the opposition of the best fathers (Theodoret, Augustin, &c.), became firmly established, and is still acknowledged in the Roman catechism. An elaborate theory of the angelic hierarchy, based on Neoplatonic doctrines, is laid down in the work of Pseudo-Dionysius, *De Hierarchia Celesti* (5th century), and exercised much influence on mediæval theology, which accepted the work as a genuine product of the apostolic age. The schoolmen treat of angels under the doctrine of creation, dividing rational creatures into angels, who are pure spirits, and men (*Sent. Lib.* ii., dist. i., *sqq.*), and the nature and powers of angels form the most notorious problems of the misdirected subtlety of the schools (*cf. e.g.*, Duns on the *Second Book of Sentences*). Protestant theologians have always felt less interest in the subject, and generally reduce the doctrine of angels to a mere appendix to the doctrine of creation or of God's works. Recent writers often go much farther. Thus, Schleiermacher sums up the whole doctrine of angels by saying, that the possible existence of angels should not influence conduct, and that revelations of their being are no more to be looked for. A reaction, partly rooted on the later philosophy of Schelling, has led several German theologians (Hofmann, &c.) to lay more weight on the doctrine.

The Biblical doctrine of angels must be studied with the aid of the best books on Biblical theology (Schulz, Oehler, Ewald, Weiss, &c.), and of the commentaries on special passages. The book of Enoch is accessible in Dillmann's translation, and other Jewish notions may be found in Eisenmenger. The literature of the subject, theological and theosophic, is immense. (W. R. S.)

ANGEL, a gold coin, first used in France in 1340, and introduced into England by Edward IV. in 1465. It varied in value between that period and the time of Charles I. from 6s. 8d. to 10s. The name was derived from the representation it bore of St Michael and the dragon.

ANGELICA, a genus of plants of the natural order of the Umbelliferæ. The name Angelica is popularly given to a plant of an allied genus, *Archangelica officinalis*, the tender shoots of which are used in making certain kinds of aromatic sweetmeats.

ANGELO, MICHEL. See MICHEL ANGELO BUONARROTI.

ANGELUS SILESIUS, a German philosophical poet, was born in 1624 at Breslau or Glatz, and died at Breslau in 1677. His family name was Johann Scheffler, but he is generally known under the assumed name which marks the country of his birth. Brought up a Protestant, and at first physician to the duke of Würtemberg, he embraced, in 1653, the Roman Catholic religion, and took orders as a priest. His peculiar religious faith, founded on his early study of the works of Tauler and Böhme, as expressed in his hymns (*Cherubinischer Wandersmann*), is a mystical pantheism founded on sentiment. The essence of God he held to be love: God, he said, can love nothing inferior to himself: but he cannot be an object of love to himself without going out, so to speak, of himself, without manifesting his infinity in a finite form; in other words, by becoming man. God and man are therefore essentially one. A selection of his hymns, which are very popular in Germany, was published in 1820 by Varnhagen Von Ense.

ANGERMANN, a river of Sweden, which rises about lat. 65° N. and long. 15° E., among the mountains that separate Sweden from Norway, and flows in a south-easterly direction through Westerbotten and Westnorrland, entering the Gulf of Bothnia near Hernosand, after a course of about 250 miles, during which it passes through several lakes. It is navigable for upwards of 50 miles from the sea, and the scenery on its banks is sometimes very beautiful.

ANGERMÜNDE, a town of Prussia, capital of a circle of the same name in the province of Brandenburg, situated on Lake Münde, 43 miles from Berlin, by the Berlin-Stettin railway. It contains about 6400 inhabitants, who are chiefly employed in the manufacture of woollen and linen goods.

ANGERS, an ancient city of France, capital of the department of Maine-et-Loire, and formerly of the old province of Anjou, situated on the Maine, about 4 miles from its junction with the Loire, and 161 miles S.W. of Paris. The streets of the upper and older quarter of the city, which occupies the slope of a rising ground on the left bank of the river, are narrow and often very steep, and the houses have a sombre, although somewhat picturesque appearance, from the quantity of slate that is used in their construction. Many of these buildings, however, have given place to others of a more modern style, particularly near the site of the old ramparts, now occupied by beautiful boulevards, while on the opposite side of the river a new quarter has sprung up, which is regularly and tastefully built. Among the principal buildings in Angers are the castle, situated on a rock commanding the city, once a place of great strength, but now used as a prison, barrack, and powder magazine; the fine cathedral of St Maurice, rebuilt in 1225, and remarkable for its beautiful stained glass windows; the Hôtel Dieu, built by Henry II. of England; and several of the parish churches. Angers is the seat of a bishop, and possesses schools of different grades, various learned societies, a library of about 40,000 volumes, and a gallery containing a good collection of pictures and statues, including some fine works by the sculptor David of Angers. There was once a university in the town, as well as a military college, at which the Earl of Chatham and the Duke of Wellington received part of their education; but the former has been abolished, while the latter has been removed to Saumur. The chief manufactures at Angers are sail-cloths, ropes, linen goods, hosiery, sugar, leather, wax, and oil; there is also a considerable trade in corn, wine, and fruits, and in the neighbourhood there are extensive slate quarries, which give employment to about 3000 workmen. Population, 58,464. Angers is the ancient *Juliomagus*, or, as it was latterly called, *Andecava*, whence the city is said to derive its present name. It was captured by Odoacer in 464 A.D., and by Clovis in 486; it suffered severely from the invasions of the Northmen in 845 and the succeeding years, and of the English in the 12th and 15th centuries; the Huguenots took it in 1585, and the Vendean royalists were repulsed near it in 1793.

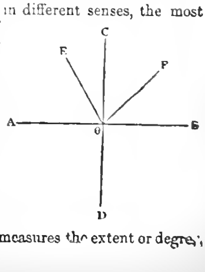
ANGERSTEIN, John Julius, an opulent London merchant, and a distinguished patron of the fine arts, was born at St Petersburg in 1735, and settled in London about 1749. His collection of paintings, consisting of about forty of the most exquisite specimens of the art, purchased by the English Government, on his death in 1822, for £60,000, formed the nucleus of the National Gallery.

ANGHIARI, a small town of Italy, in the province of Arezzo, situated 10 miles N.E. of Arezzo, not far from the Sovara, a tributary of the Tiber. The Milanese, under Niccolo Piccinino, were here defeated by the Florentines in 1440. Population of the commune, 6,000.

ANGILBERT, St, the most distinguished poet of his age, was the secretary and friend of Charlemagne. After filling the highest offices under that monarch, and receiving the hand of his daughter Bertha in marriage, he retired in 790 to the monastery of Centule, or Saint Riquier, of which in 794 he was made abbot. He left this retreat from time to time when the king required his services, and in 800 assisted at Rome at his coronation. He died in 814. Angilbert was called by Charlemagne the *Homer* of his time.

ANGINA PECTORIS, a term applied to a violent paroxysm of painful sensations in the chest, arising for the most part in connection with some form of heart disease. An attack of angina pectoris usually comes on with a sudden seizure of pain, felt at first over the region of the heart, but radiating through the chest in various directions, and frequently extending down the left arm. A feeling of constriction and of suffocation accompanies the pain, although there is seldom actual difficulty in breathing. When the attack comes on, as it often does, in the course of some bodily exertion, the sufferer is at once brought to rest, and during the continuance of the paroxysm experiences the most intense agony. The countenance becomes pale, the surface of the body cold, the pulse feeble, and death appears to be imminent, when suddenly the attack subsides, and complete relief is obtained. The duration of a paroxysm rarely exceeds two or three minutes, but it may last for a longer period. The attacks are apt to recur on slight exertion, and even in aggravated cases without any such exciting cause. Occasionally the first seizure proves fatal; but more commonly death takes place as the result of repeated attacks. Angina pectoris is generally held to be a *neurosis*, or nervous affection of the heart, but its causation is still a matter of uncertainty. It seems occasionally to manifest itself where no organic heart disease is discoverable, either in life or after death, but in the great majority of cases some morbid condition of the heart's structure is undoubtedly present. A diseased state of the coronary arteries, the nutrient blood-vessels of the heart, has been found in a large proportion of the cases examined *post mortem*; but, on the other hand, these arteries may be found diseased where no paroxysm of angina had ever occurred; and further, it is well known that various other forms of heart disease may have angina pectoris associated with them as a prominent symptom. Angina pectoris is extremely rare under middle life, and is much more common in males than in females. It must always be regarded as a disorder of a very serious nature. In the treatment of the paroxysm much relief is obtained by opiates, and by the inhalation, under proper precautions, of anæsthetic vapours, such as ether, chloroform, and nitrite of amyl. To prevent the recurrence of the attacks, something may be done by scrupulous attention to the state of the general health, and by the avoidance of mental or physical strain, for it is certain that attacks in those who are the subjects of the disorder are often precipitated by errors in living, and by undue exertion or excitement.

ANGLE, a term employed in different senses, the most common and simplest use of it—to which all the rest may be referred, and by which they may be explained—being to indicate the inclination of two straight lines to each other. Suppose O F in the figure to turn about O from the position O B towards O C, like the opening out of the legs of a pair of compasses, the angle formed by O B and O F, which is distinguished as the angle B O F, measures the extent or degree



of the turning or opening, being of course entirely independent of the length of the lines. The ordinary method of measuring angles is based on the division of the circumference of a circle into 360 equal parts, called degrees, the angles formed by lines radiating from the centre being proportional to the arcs of the circumference which the lines intercept. If O C makes equal angles with the straight line A O B, each of them is a right angle, or an angle of 90°. In the figure A O E is an angle of 60°, and C O F and F O B are each 45°; whence E O F is 75°, E O B 120°, &c. By the angle curved lines make with each other is meant the rectilineal angle contained by the tangents to the curves. See GEOMETRY and TRIGONOMETRY.

ANGLES. According to the usual account, which rests on the authority of Bede, the Angles were one of three tribes who passed over from the Continent in the 5th and 6th centuries, and taking possession of different parts of England, formed the main and dominant element in its subsequent population. The Saxons, he tells us, and he is followed by the authors of the Saxon chronicles, were situated in what is now Holstein; the Angles occupied the district to the north, probably extending across the peninsula, and beyond the Angles were the Jutes, in (approximately) the modern Jutland. Hypothetically they are identified with the *Angli* of Tacitus, who were seated on the Lower Elbe; and certainly they belonged to the Low German race. Some historians, as Professor Henry Morley, regard the distinction between Saxon and Angle as a mere accidental difference of name; the people themselves employing the name of Angles, while Saxon was a foreign designation applied to them by the Romans and Celts; and this view might be supported by the fact that, while the boys admired by Gregory, according to the well-known tale, were "Angles," his missionaries were sent to the Jutish kingdom of Kent. It must be admitted, however, that whatever the origin of the words Angle and Saxon may be, they expressed, from the time of the invasions downwards, a difference that was, if not radical and of long continuance, at least real and obvious. The Angles were a strong and vigorous people, and not only founded three kingdoms in England,—Northumbria, East Anglia, and Mercia (which all, and especially the first, exercised a great influence on our early history),—but also spread through a large part of the Lowlands of Scotland. Their language was soon brought under literary culture, and supplied a groundwork for the later and richer developments of the southern Saxons; and it is still to be distinguished in the Northumbrian dialect and the Lowland Scotch. They have left us, though in the form of a *rifacimento*, one of the most remarkable literary legacies we possess—the poem of Beowulf, and claim the honour of producing Cædmon and the venerable Bede. See Thorpe's Lappenberg; and Morley, *Writers before Chaucer.*

ANGLESEA or ANGLESEY (*i.e.*, the Angle's Island), the *Mona* of Tacitus, an insular county of North Wales, separated from the mainland of England by the Menai Strait, over which Mr Telford's magnificent suspension bridge was thrown in 1826, followed by the renowned tubular railway iron bridge in 1850. The island contains 193,511 acres. The surface is for the most part flat, and the soil but moderately fertile. The exports consist of barley, oats, cattle, sheep, and hogs; and a considerable trade is carried on in butter, cheese, hides, tallow, wax, and honey. It contains valuable minerals, and furnishes (though not so abundantly as formerly) copper, lead, silver, marble, asbestos, limestone, marl, and coal. The chief copper mines are at Parys, and were first worked in 1768; and those of coal are at Maltraeth and Tredfaeth. The stones for the towers of the tubular bridge were quarried at Penmore, 4 miles north of Beaumaris. There are no manufactures of importance. The herring fishery in some years gives employment to a part of the inhabitants; and other kinds of sea-fish are abundant. Anglesea was anciently famous as the seat of the Druidical pontiff, and a Druidical college; and a number of (so-called) Druidical remains—such as the cromlechs at Plas Newydd—are still to be seen. In 61 A.D. Suetonius Paulinus attacked the Druids in this their safest retreat, and they were utterly subdued by Agricola in 78. About 450 Caswallon, prince of Cambria, chose this island for his seat of government, and it continued to be the residence of the princes of North Wales till the final subjugation in 1277. At present the northern form of Welsh is spoken by the peasantry, but in the towns English is very generally understood. The county is divided into 6 "hundreds," and 76 parishes. The number of inhabitants in 1861 was 38,157; and in 1871, 35,127. This decrease is ascribed to emigration, occasioned by the depressed state of the mining trades and lack of agricultural employment. The county returns one member to parliament, and one is also returned by the boroughs of Beaumaris, Holyhead, Amlwch, and Llangefni.

ANGLESEA, ARTHUR ANNESLEY, EARL OF, lord privy seal in the reign of King Charles II., the son of Sir Francis Annesley, Lord Mount-Norris, and Viscount Valentia, in Ireland, was born at Dublin 10th July 1614. He was for some time at the university of Oxford, and afterwards studied law at Lincoln's Inn. In the beginning of the civil war he sat in the parliament held at Oxford; but afterwards became reconciled to the opposite party, and was sent commissioner to Ulster in 1645, to oppose the designs of the rebel Owen Roe O'Neal. He was president of the council of state after the death of Cromwell, and was principally concerned in bringing about the Restoration. He succeeded to his father's titles in 1660, and in 1661 was enrolled in the English peerage as Lord Annesley of Newport-Pagnell, Bucks, and Earl of Anglesea. During Charles's reign he was employed in various important affairs, was made treasurer of the navy, and for some time held the office of lord privy seal. Annesley was a person of great abilities and of very extensive learning, and was well acquainted with the constitution and laws of England. In his lifetime he published several works, chiefly of a polemical and political character. He died in April 1686.

ANGLESEY, HENRY WILLIAM PAGET, FIRST MARQUIS OF, one of the most distinguished British generals of the 19th century, was born on the 17th of May 1768. He was the eldest son of Henry Lord Paget, first Earl of Uxbridge, of whose family of twelve sons and daughters he was the last survivor. He received his early education at Westminster school, and passed thence to Christchurch, Oxford, where he took the degree of M.A. Quitting the university in 1790, he entered parliament the same year as member for the Carnarvon group of boroughs, for which he sat six years. But to his high-spirited and impetuous nature the soldier's life was most attractive; and during the excitement which was occasioned by the outbreak of the wars of the French Revolution, Lord Paget raised on his father's estate the regiment known at first as the Staffordshire Volunteers, and afterwards as the 80th Foot in the regular army. Of this regiment he was named lieutenant-colonel. Having entered the army, and passed rapidly through the subordinate grades, he obtained his commission as lieutenant-colonel on the 12th September 1793. In the following year he commenced his career of active service in the campaign of Flanders, under the Duke of York. So greatly did he distinguish himself, especially during the retreat which followed the repulse of Turcoing, that notwithstanding his youthful years, he was appointed, in the temporary absence of Lord Cathcart, to the command of his brigade. Transferred soon after his return to England to a cavalry regiment, 16th Light Dragoons, he was thenceforth attached to that branch of the service which he was to raise to the highest degree of efficiency, and in connection with which he was to achieve his greatest triumphs. About the same time (July 1795), Lord Paget married Lady Caroline Elizabeth Villiers, daughter of the Earl of Jersey. Promoted colonel in 1796, he was transferred in April 1797 to the command of the 7th Light Dragoons, and then began to apply himself strenuously to the improvement of discipline, and the introduction of a new system of cavalry evolutions. In 1799 he took part in the campaign, brief and disastrous, of the Duke of York in Holland. In the general attack (Oct. 2) he distinguished himself by a dashing and successful charge on a superior body of the enemy's cavalry. On him devolved the arduous task of guarding the rear in the retreat, and while thus engaged, he routed a much larger body of French cavalry under General Simon, recovering some captured cannon, and taking five of the enemy's guns. Devoting himself through the following eight years, with zeal equal to his abilities, to the discharge of his regimental duties, and to the perfecting of the reforms which he had previously introduced, he attained the rank of major-general in April 1802, and that of lieutenant-general in April 1808. At the close of this year the great war with the French in the Peninsula began, and Lord Paget was sent, with two brigades of cavalry, to join the division of the army under Sir David Baird, who was then marching to join Sir John Moore in his advance on Salamanca. He landed at Coruña, and in the face of very great difficulties succeeded in effecting the junction. It was during this march that the first conflict with the French in Spain took place,—a small party of French posted at Rueda being surprised and cut off by Lord Paget. In the retreat ordered by Sir John Moore, after the fall of Madrid, Lord Paget was charged with the protection of the rear, and, notwithstanding the frequent harassing attacks of the enemy, the losses of the British were trifling. He especially distinguished himself by brilliant and successful encounters with the French at Sahagun, Mayorga, and Benevente. His spirited repulse of the advanced guard of the French at Benevente, where he also captured the commander of the imperial guard, General Lefebvre Desnouelles, especially contributed to the safe arrival of the British at Coruña. At the battle of Coruña, fought on tha 16th January 1809, and mournfully memorable for the fall of the brave Sir John Moore, Lord Paget had the command of the reserve; and while the dying commander was being carried from the field, his lordship, by a swift, courageous movement, repulsed a superior force of the enemy, thus deciding the fate of the day and securing the safe embarkation of the British army. With this action his services in the Peninsular war terminated, and in the autumn he returned to England, where he applied himself to his parliamentary duties as member for Milbourne Port. He sat for that borough six years (1806 to 1812). In 1810 he obtained a divorce from his wife, by whom he had had eight children, but with whom he had not lived a happy life. The same year he married Lady Cowley, who had about the same time been divorced from Lord Cowley. Lady Paget was soon after married to the Duke of Argyle. In 1812 he succeeded his father and took his seat in the House of Lords as Earl of Uxbridge. Three years later his services as general were called for on a grander field, and his reputation was raised to the highest pitch. In the spring of 1815 all Europe was startled by the news of the escape of Napoleon I. from his island prison, Elba, of his reappearance in France at the head of an army, and of his reassumption of the imperial dignity. Without delay the armies of the allies were sent again into the field, the English under the Duke of Wellington as commander-in-chief, and the English cavalry under the command of the Earl of Uxbridge. At the decisive battle of Waterloo (18th June), after twice leading the guards to the charge, he placed himself at the head of the heavy brigade, and, by a third rapid and terrific charge, completely overwhelmed the trusted French guards, led by Count D'Erlon, making 3000 prisoners, and killing most of the rest. Other brilliant feats followed, which won for the Earl of Uxbridge on that day a place of honour second only to that of the great duke himself. In the confusion which followed, Napoleon, from a low rising ground, directed the fire of four guns, and by one of their discharges, almost the last shot that was fired, the earl was struck on the knee, and amputation of the limb was found to be necessary. This was effected in a private house at Waterloo, and the limb was buried in the garden. Visitors are shown the chair in which the earl sat during the operation, the boot taken from the amputated leg, and the monument over its burial-place. A pension of £1200 a year was voted to him on account of the loss of his limb, but he generously declined to accept it. Five days after the battle the services of the earl were rewarded by the dignity of Marquis of Anglesey, conferred on him by the Prince Regent; and he was soon after nominated Knight Grand Cross of the Bath. Similar honours were bestowed on him by the emperors of Austria and Russia and the king of Hanover. In 1818 he was elected Knight of the Garter. He attained the full rank of general in the following year. His support of the proceedings against Queen Caroline made him for a time unpopular, and when he was on one occasion beset by a crowd, who compelled him to shout "The Queen," he added the wish, "May all your wives be like her." At the coronation of George IV. the Marquis of Anglesey filled the post of lord high steward of England. At the close of April 1827 he became a member of the Canning administration, taking the post of master-general of the ordnance, previously held by Wellington. He was at the same time sworn a member of the privy council. Under the Wellington administration he accepted the appointment of lord-lieutenant of Ireland (March 1828), and in the discharge of his important duties he greatly endeared himself to the Irish people. The spirit in which he acted, and the aims which he steadily set before himself, contributed to the allaying of party animosities, to the promotion of a willing submission to the laws, to the prosperity of trade, and to the extension and improvement of education. On the great question of the time his views were opposed to those of the Government. He saw clearly that the time was come when the relief of the Catholics from the penal legislation of the past was an indispensable measure, and in December 1828 he addressed a letter to the Roman Catholic primate of Ireland distinctly announcing his view. This led to his recall by the Government, a step sincerely lamented by the Irish. He pleaded for Catholic emancipation in parliament, and on the formation of Earl Grey's administration, in November 1830, he again became viceroy of Ireland. The times were changed; the great act of emancipation had been accomplished, and the task of the viceroy in his second tenure of office was to resist the agitation commenced and carried on by O'Connell. He felt it his duty now to demand Coercion Acts for the security of the public peace; his popularity was diminished, differences appeared in the cabinet on the difficult subject, and in July 1833 the ministry resigned, the viceroy retiring at the same time. To the Marquis of Anglesey Ireland is indebted for the Board of Education, the origination of which may perhaps be reckoned as the most memorable act of his viceroyalty. For thirteen years after his retirement he remained out of office, and took little part in the affairs of government. He joined the Russell administration in July 1846 as master-general of the ordnance, finally retiring with his chief in March 1852. His promotion in the army was continued by his appointment to the command of the horse guards in 1842, and completed by his advancement to the rank of field-marshal in 1846. A life of brave service and faithful devotion to duty was closed by a peaceful death on the 29th April 1854. The character of the Marquis of Anglesey, appreciated and admired by all classes and parties, was sketched by a contemporary journalist in the following terms:—"Seldom have bravery, gentleness, and generosity been combined in such noble proportions. In his character there was not a fold, it was all open as the day. His politics were thoroughly liberal, and with more far-sighted and sound statesmanship in them than the world has perhaps given him credit for. . . . He had a sound, shrewd understanding, a judgment seldom at fault, often acting like an instinct, and accompanied with a moral courage not inferior to his brilliant physical bravery in the field of battle." He strenuously supported every measure of reform in church and state, and, with sagacious forecast anticipating public opinion, earnestly advocated in their days of unpopularity the great measures of Catholic emancipation, parliamentary reform, and free trade. The marquis had a large family by each of his two wives,—two sons and six daughters by the first, and six sons and four daughters by the second. His eldest son, Henry, succeeded him in the marquisate. (W. L. R. C.)

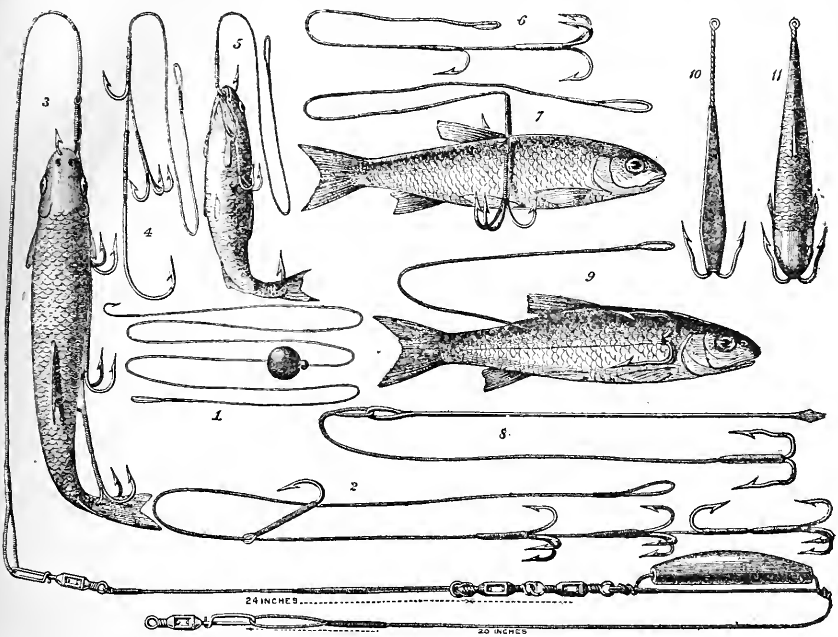
ANGLING

THE art of angling, or of catching fish by a rod and line, is of very ancient derivation. The earliest writer upon it in our country was the Dame Juliana Berners, who wrote a treatise on it in the *Book of St Albans*, printed by Wynkyn de Worde in 1496. Between that time and the present there have been nearly a thousand books, or parts of books, written and published upon this subject.

The practice of angling may be arranged under three heads, viz., top or surface, mid-water, and bottom angling. Surface angling includes fishing with an artificial fly, or daping with a live fly or other insect; mid-water fishing includes spinning or trolling with a dead bait and fishing with a live bait; bottom fishing includes angling with worms and other baits, either resting on or travelling with the stream along the bottom. The last is usually the first practised by the angler, and we will therefore take it first.

Bottom Fishing.

The school-boy who comes home for the midsummer holidays, usually commences his apprenticeship to the art of angling by fishing for some of the carp tribe in some pond or river near his residence. For this purpose he provides himself with a rod usually of from 12 to 14 feet long, and generally made of bamboo-cane, which is the best for the purpose. A small reel, with 30 or 40 yards of silk line, a light quill float, a yard or two of fine silk-worm gut, and a hook tied on at the end of it, which for general work should be either Nos. 6, 7, 8, or 9 in size, and a few split shots pinched on the line for sinkers. He then plumbs the depth of the water by the aid of a plummet, and fixes his float on the line at such a depth that the hook barely or just touches the bottom. His chief baits are worms and gentles or maggots. The worm (the reddest are the best) is stuck on the hook by being threaded from head nearly to the tail. The gentles, to the number of two or three, being stuck on as may be convenient. For gentles the smaller hooks are used; and the hook being baited, is cast into the water and hangs suspended by the float. When there is a bite the float bobs under, and the angler jerks the rod up or strikes, hooks his fish, and, if a big one, plays it,—that is, allows it to swim violently about until tired,—when he draws it ashore and lands it. In still-water fishing for carp, tench, roach, &c., the angler uses now and then a handful of what is termed ground-bait to draw the fish round his hook. There are many substances used for this,—worms, gentles, grains, boiled barley or wheat, &c., &c.,—but the best and most general is a mixture of bran, soaked bread, and a little boiled rice worked up together; if with this is mixed a few handfuls of carrion gentles, usually obtained from horse slaughter-yards, there is no better bait. To ensure sport it is often necessary to bait a spot, or pitch, as it is termed, one or two evenings previously. In still-water fishing this is all that has to be done. In bottom fishing in running water the same preliminaries are observed in taking the depth of the water, baiting, &c.; but when the tackle is dropped into the water the stream carries it along, and the angler, keeping the top of his rod over his float, follows it down his swim, as it is called, until he reaches the end, or as far as he desires to fish, when he pulls his tackle out, and returns to the head of the swim, and recommences striking at every bob or dip of his float. In stream fishing he must either cast his ground-bait in so far up stream that it will find bottom in his swim, or he must knead it into balls with a stone in the middle or mixed with clay, so as to sink it to the bottom at once. In choosing a swim on the banks of a river, if the angler cannot see a good stock of fish anywhere, he should choose some spot which fish may be supposed to haunt,—a spreading root, or bough, or overhanging bank with a hole under it, a deep hole near banks of weeds, or a deep eddy off some sharp stream. Here the bottom should be pretty level and free from obstructions, and the stream not too swift nor too slow, so that the float may travel steadily and evenly without hinderance throughout. If he cannot decide on any spot, let him look along the bank for places worn by the angler's feet, or where *debris* of bran, &c., points out that some angler has previously fished and baited the stream. Having baited a pitch one day, it should never be neglected on the next, as the fish will have had time to find out the bait, and will perhaps be collected together there. Of course the choice of a pitch will be guided very much by the species of fish the angler desires to fish for. The places they frequent are noted hereafter. When the angler has hooked a big fish which he cannot lift out without danger to tackle, he uses a landing-net, that is, a bag-net on an iron ring fastened to the end of a pole, which he slips under the tired fish and lifts securely to the bank. When fishing on a river bank the last words in Walton's *Complete Angler* are to be strictly observed, viz., "Study to be quiet," for violent disturbance or motion is fatal to sport. Having deliberately chosen a pitch and baited it, the angler should not desert it hastily, or if he leaves it for a time for another, he should return to it and give it another trial. In angling from a punt or boat a shorter rod is used than from the bank, from 10 to 12 feet being the limit. In the Thames plan the punt or flat-bottomed boat is fixed directly across the stream by means of two iron-shod poles which are driven into the bottom. The depth being taken, and the ground-bait thrown in, the angler, sitting with his face down stream, drops his tackle in close to the boat, and allows it to float down stream unchecked as far as the line, which is generally a yard or two longer than the rod, will permit, when he strikes, pulls up the tackle, drops it again in close to the punt, and repeats the operation time after time. In the middle of these punts there is generally a well, so that the fish when caught are kept alive in the well until the day's fishing is over. On the Trent the method adopted is different. The punt or boat, if used at all, is fixed diagonally and not directly across the stream. A very fine and light silk line is employed, which will float easily and does not sink much at any time. A very easy-going reel or winch is used, which turning on an oiled spindle lets off the line very rapidly, and is set running with the lightest touch of the finger. The rod being held at an angle of 90°, the line is allowed to run freely, until the float and bait go sometimes as far as 50 or 60 yards down the stream,—a plan which has many advantages, as much more ground is covered than in the restricted swim of the Thames method, and the fish are less shy in biting so far from the boat. The ground-bait is usually thrown in loosely above the punt, and generally consists of chopped worms or greaves (tallow-melters' refuse), and as the swim is so long an one the ground-bait is certain to fetch the bottom somewhere within it. In Norfolk a different plan still is adopted. The punt is anchored lengthwise straight up and down, and the anglers fish on either side of it; but the water being usually very deep the rods are longer and the tackle heavier, and besides the moving float they have another rod, the tackle to which is so heavily weighted that the baited hook rests on the bottom, and is not to be moved by the stream—the fish picking up the bait at leisure, and the float showing the bite. This is termed "tight corking." These are the chief methods employed in float fishing at the bottom. But other methods of fishing with a stationary bait without a float are often



adopted. The ledger is the chief of these (see fig. 1 in the cut). This consists of a gut line a yard or two long, which runs through a bullet or a lump of lead pierced with a round hole. On the hook side of the line an obstruction is fastened so that the lead cannot slip down to the hook, but the line is free on the rod side of the lead. The hook being baited, the lead is dropped into the water and rests on the bottom, a tight line between the rod top and the lead being kept. The instant a fish bites at the hook, the line being free in that direction, it is felt at the rod top, and the angler, yielding a little line to let the fish get the bait and hook well in his mouth, strikes, lifting the lead, and so hooks the fish. Another method, called the clay-ball, is to tie a bit of stick across the line a little above the hook, which is baited with gentles and greaves, and then to weld a lump of clay and ground-bait on the line round about the bit of stick. This is dropped to the bottom, and the fish, attracted by the ball of bait, come up to devour, and in time find the baited hook and take it most unsuspectingly. Sometimes the baited hook is buried in the ball of bait, and the fish are allowed to dig it out. Sometimes a float is used in conjunction with a small clay ball to show the bites. Another plan of bait fishing at the bottom is with a free line, with only a very light sinker of a split shot or two on the line. The hook is baited with a worm, and allowed to travel along the bottom, the bite being felt or seen in the action of the line on the water or the rod top. This is chiefly employed in trout fishing.

Mid-Water Fishing.

Spinning is the first branch of this kind of fishing, and is used chiefly for pike and trout, though salmon and other fish occasionally are fished for and taken thus. It consists in drawing along through mid-water a bait so disposed on a series of hooks as to revolve rapidly, thus showing its silvery sides constantly to the fish of prey, and attracting them to run after it and capture it, when the hooks which are about it in turn capture them. A small fish—a little trout, dace, gudgeon, or bleak principally, as these are the best fish for the purpose—is hung on a range of hooks called a flight. This flight generally or mostly consists of three triangles, or three hooks welded back to back, tied upon gut or gimp at intervals of half an inch or so, a reversed hook near the tail to keep it bent, and above them a sliding hook working in an eye, called the lip hook (see fig. 2 in cut). A fish is then chosen suitable to the length of the flight, the lowest triangle is stuck on the middle of the side of the tail, the reversed hook just above it is then stuck into the fish a little below the vent, so as to keep the tail of the fish bent or crooked. The other two triangles are then stuck into the side of the bait in a straight line towards the fish's mouth. The line is then twisted two or three times round the shank of the lip hook, so as to bring it just to the bait's mouth and to keep it firmly there. The hook is then passed through both lips of the bait, and the bait is ready for use (see fig. 3 in cut); then it is hung on to a tackle called the trace. This consists of a yard or two of gut, single or twisted, or gimp, as may be desired; and at intervals of 18 or 20 inches or so, one or more swivels are placed to permit the bait to revolve freely without also turning the line, which would cause the whole running line to snarl and tangle, and a lead or sinker, so disposed as to promote the same object, is put on just above the swivels, aud the trace is complete. (The upper part of the tackle in fig. 3 from swivel to swivel shows the trace). The whole apparatus then being looped on to the main or reel-line, is dropped into the water, and being drawn rapidly through it, if the bait be properly arranged on the hooks, spins with wonderful swiftness, often like one long line of flashing silver. If it does not spin well, but "wobbles," as it is termed, the hooks are not properly fastened into the bait, and either do not lie straight and even along the side, or the head or tail of the bait is too slack or too tight. This must be amended as the bait cannot spin too well. The object of its spinning well is not only to attract the fish, but to conceal the hooks. The arrangement of the hooks on the flight given above is the one most commonly adopted by Thames spinners, who are the best hands in this branch of fishing, but there are many other arrangements which are sold by tackle-makers, of which the Francis and Pennell tackles are perhaps the chief. The reel-line used in spinning is usually made of plaited silk, dressed with a composition to stiffen it and to prevent tangling; and the line is heavier or lighter according as the bait and tackle to be used is heavier or lighter. In working a spinning-bait, the angler first tries all the nearer water to the spot where he stands, and gradually lengthens his line, allowing it to lie loose on the ground, or in the boat or punt's bottom, in coils at his feet Then with about half as much line as the length of rod hanging down from the rod point, he gently waves the bait backwards to the left or right, according to the side he wishes to cast to, and then suddenly urging the rod forward with a sweep, releases the running line which he has held fast against the rod, and the impetus the bait has acquired by the swing sends it forward from 20 to 40 yards towards the point the angler desires to cast to; then lowering the point of the rod to allow the bait to sink to mid-water, he holds the rod in the right hand, and draws the line home through the rings with the left hand, allowing it to fall at his feet as before, and raising and dipping the rod at every draw, makes the bait spin and shoot, and rise and fall, as it comes towards him, in a most attractive manner. The line being all drawn in, lies at his feet as before, and lifting the bait out of the water again, he repeats his cast in a new direction, and having fished all the water within reach he moves on. Should a fish run he feels a jerk at the rod point, or sees the line stop, and he strikes smartly and plays his fish, drawing in line by hand, and taking care that no tangle ensues. To avoid this at any time, he must see that there are no twigs or other obstructions about his feet where the line rests between each cast, which may catch in the coils and cause a snarl or knot, as this spoils the cast by preventing the line from running. In trout spinning smaller and lighter tackles, rods, and lines are used than are employed for jack. For the big Thames trout, and for trailing for the great lake trout, similar fashioned but lighter flights and traces are employed; but for spinning the minnow for small river or brook trout a different kind of flight is used. This flight is shown unbaited and baited at figs. 4 and 5 in the cut. The big hook is inserted into the mouth of the minnow, and by a little humouring the point is carried down the body along the back-bone to the tail, where it is brought out, and the lip hook inserted through both lips of the bait; and, if any attention has been paid to the size of the minnow selected, the tail will be nicely bent round on the curve of the hook so as to make the bait spin rapidly. Many anglers do not use any other hooks than these two; but it is so easy for a trout to run and seize such a bait and to miss being hooked, that to make sure, it is usual to employ in addition the little triangle of hooks, which is inserted half way down the side of the bait. Even with this safeguard, when fish are running shyly, the angler will find that he misses from one-third to one-half of the runs which he gets. In spinning for small trout various methods are pursued: some fish down stream, some up; and where it is requisite to wade, and a moderate rod is used, it is best to fish up, wading in mid-stream, and casting on either hand towards the opposite banks, the angler brings the bait diagonally down towards him, with a curving sweep in front. When, however, he can fish from the bank, it is best to fish down, and to cast across, drawing with a diagonal sweep up stream. Usually it is just as the bait is making the bend round that the fish seizes it, and therefore it behoves the angler to keep a sharp look out then. Some anglers cast the minnow over hand, and some under; the best plan is to cast it under, and, taking hold of the reel-line between two of the rings on the middle joint of the rod with the left hand, to draw a good portion of line off the reel, holding it tight until the cast is made, when it is released, and doubles the length of cast which the angler could make in the ordinary way,—as in minnow fishing the tackle is too light, as a rule, to cast off loose line from coils on the ground, and so, ordinarily, little more line than a yard or so more than the length of the rod can be used; by this means, however, nearly double that length can be got out. Of course the weight or sinkers on a minnow tackle will be proportionate to the requirements of the stream, and though the trace will be of lighter gut than it is customary to use for large trout, the fashion of the tackle is similar. In this case, also, there are many other arrangements of hooks used, but there are none so good as the one figured in the plate. In the north there is another method of spinning practised, called par-tail fishing, which is used chiefly when and where minnows are difficult to obtain, though some persons prefer par-tail as a bait to minnow. For this only two hooks are used similar to the two in the figure for minnow fishing, minus the triangle. A par is taken and cut diagonally in two from the front part of the dorsal fin to the middle of the space between the ventral and anal fins. The tail part being taken, and the tail snipped off, the lip hook is put through the root of the tail, and the big hook stuck into the bait so as to curve the broad end of the bait on to the hook; the bait, if properly adjusted, spins pretty well. Some anglers, however, cut a slice out of the back from before the dorsal fin down to the tail, leaving a small part of the tail and only part of the belly, and by adjusting this on hooks suited to it, it rather more resembles the natural fish. These baits are used exactly like the minnow.

In fishing for larger trout, as the large lake trout or the *Salmo ferox*, the method generally adopted is that of trailing. Here a small trout or par is used on the three-triangle tackle already mentioned above. The line is weighted according to the depth of the water, and the boat is rowed slowly along, some 30 or 40 yards of line being let out, so as to permit the bait to sink and to tow some distance astern. Two rods are chiefly employed for this sport—one being placed at each corner of the stern of the boat, and each having on a different bait, weighted differently, and with a longer or shorter line out, so as to give any fish inclined to feed a double chance. The proper line to take for these large trout when moving along the shores of a lake is just where the water begins to go off between the deep and the shallow; and the bait should travel as near to the bottom as it can, without catching in weeds or stumps; as, though fish will frequently rise some distance to a bait, it is not desirable to compel them to do so. When a big lake trout strikes, he usually runs heavily, and bores down to the very depths of the loch, showing fine sport. They frequently run to a large size, reaching 16 and 18 ℔ weight, and sometimes heavier. They are, however, better for the table when 4 or 5 ℔. The small lake trout are spun for by trailing a minnow in the same way, but in shallower water; and often when the fish are dull at the fly, they take well on the trail. There are various artificial baits used for spinning, some of them imitating fish of different kinds, and made of bone, horn, gutta-percha, mother-of-pearl, glass, and other substances. One of the best and most generally known and used is the "phantom bait," invented and made by Mr Brown of Aberdeen. It is made of oiled silk, and painted to represent a small trout or par; being cylindrical, when drawn against the stream, it fills with water and plumps out to the size of a fish; when seized, however, it compresses to a mere rag of oiled silk, leaving nothing but the hooks in the fish's mouth. There are various other spinning-baits which do not exactly imitate any fish, as spoons, otters, kill-devils, &c.

Live Baiting.—The plan pursued in this kind of fishing for pike is generally to use either what is termed "live snap or gorge tackle." In the former, the object is to strike as soon as the pike takes the bait into his mouth; in the latter, to allow him to swallow or gorge it. In both cases a float is used. This is usually a lump of cork nearly as large as a hen's egg, to carry a good-sized bait. The bait used generally is either a small roach, dace, or gudgeon; failing these, any other that can be obtained. The best kind of snap tackle may be seen in fig. 6. In the cut it consists of a single hook and a triangle. The single hook is hooked through the root of the dorsal fin of a small roach, dace, or gudgeon, and the triangle hangs down at the side of the bait, as shown in fig. 7. Now, when a pike first seizes a bait he takes it across his mouth, so that while the head and tail appear outside his jaws on either side, the whole of the middle parts of the body are well within them; and, as will be seen from the position of the hooks, they will most probably be within the pike's mouth also; consequently, as soon as the pike has had time to take the bait so arranged into his mouth, the angler strikes smartly, and very often hooks his fish and lands him. It will of course happen sometimes that the triangle is not well in the fish's mouth, in which case either the fish is missed altogether, or, being very slightly hooked, he breaks away. Another method of using the live bait is what is termed the "live gorge." In this case a pair of hooks, tied back to back, are used. The loop of the gimp on which they are tied is hooked into a long needle, called a baiting needle. (See fig. 8, which shows the hooks and the needle.) This is inserted under the skin at the shoulder of the bait, and carried down just under the skin, towards the tail, being brought out just behind the dorsal fin. The gimp is drawn through, and the hooks stand as shown in the illustration. (See fig. 9.) In the illustration the loop is hung on to the trace, and the tackle used as in ordinary live bait fishing; only, when a pike takes the bait he is allowed to gorge it before the angler strikes, being permitted to go where he will with the bait, and ten minutes being allowed for him to gorge or pouch, as it is termed. This is a tedious method of fishing, and is only used for pike,—as often the fish runs the line foul of some weed, and leaves the bait; or, after mumbling it and killing it, refuses to gorge, and the constant waiting whenever there is a run is wearisome. But as there is less show of hooks, more runs are obtained in clear water than with the live snap tackle. Another method of using the live bait is with the paternoster, though this is chiefly used with minnow or small fry for perch fishing. It is, however, sometimes used for pike, when a gimp tackle is preferred and only two hooks used. For perch fishing, the paternoster simply consists of a line of gut about 4 or 5 feet long; at the bottom of this is a leaden bullet or plummet to sink it to the bottom; about 6 or 8 inches above this a hook, on some 6 inches of gut, is fastened; a foot above this another hook is fixed on, and a foot above that again, a third. This third hook is often a gimp hook, when pike and perch are found in common, and a rather larger hook and bait are used, so that if a pike should come to the bait, there may be a fair chance of capturing him. A minnow being hooked through the lips on each of the other hooks, the tackle is dropped into an eddy where perch are supposed to be, and the three baits swim round and round the main line; so that, no matter whether the fish are resting at the bottom or searching for their prey in mid-water, they may be attracted. As soon as there is a bite from a perch the angler feels it at the rod-point, slackens line for two seconds to let the fish get the minnow well into his mouth, and then strikes. Should the immediate neighbourhood not afford a bite, the tackle is cast to a distance, and after being allowed to rest for a minute, it is drawn in a few feet, when another cast is made, and then another draw, until the tackle is worked up on the boat or bank, when another cast is made. In the winter, after the floods, very many perch are caught in this way on the Thames, from 100 to 200 in a day being not very uncommonly taken. Trolling with the dead gorge is another way of fishing; and this is employed chiefly when the water is full of thick weeds and rush-beds, which prevent either spinning or live bait fishing, and solely also for pike. An elongated piece of lead is cast on to a bit of twisted brass wire, which has a couple of hooks similar to those on a live bait gorge tackle at the other end (fig. 10); a gudgeon (which is the best bait for the purpose) to suit the length of the lead is chosen; the loop of the gimp, to which the brass wire is fastened, is slipped into the eye of a baiting needle. The needle is passed in at the mouth of the bait and down along the spine, out at the tail. The lead being drawn into the stomach of the bait, the two hooks lie on each side of the mouth. The tail is tied tightly on to the gimp with three or four laps of silk, to prevent it from slipping (see fig. 11), and the tackle and bait fastened on to the trace used, which is usually a yard of gimp, with one hook or spring swivel to loop the tackle and bait on. This bait is then dropped into holes between the weeds or rushes, and is worked up and down by the lifting and falling of the rod-point, the lead within the bait causing it to shoot and dart along as though the fish were alive. When a pike seizes it, ten minutes must be allowed for him to pouch, when the angler must strike firmly, hold on, and get his fish out as well as he can. It is by no means the pleasantest method of fishing, as the waiting is tedious. The fish constantly runs the line foul of the weeds, &c.; and often, after a tedious waiting, it is found that the fish has rejected the bait after all. Added to these, there is this objection to all gorge fishing, that the angler must kill every fish he catches, as the hooks are in the fish's throat, and small under-sized fish, which ought to be returned to the water, are sacrificed, as well as fair takeable ones

Sometimes grubs and worms are used in mid-water fishing, being cast up stream and allowed to float down in mid-water This is chiefly for trout. The angler uses a long, light bamboo rod, and a single shot for a sinker. Two small worms are generally used; the brandling or gilt-tail is more frequently used (a worm found in rotten manure, &c.) Some use a single hook, some three small hooks tied one above the other. This is called "the Stewart tackle," after the author of the *Practical Angler;* and the worms are twined round and impaled on them. Wading up stream, the angler casts before him into every likely stream and eddy, allowing the line and bait to come down towards him in mid-water, and striking the moment he perceives a check. This is a very killing plan, and is adopted with a modification of tackle, to fish with beetles, larvæ, palmers, and, in fact, almost any kind of insect; for the trout is a very omnivorous fish, and will hardly refuse anything that is small enough. The lure is cast overhand, as in fly-fishing, and practice enables the angler to cast nearly twice the length of the rod.

Surface or Fly Fishing.

This method of fishing is conducted with the natural or the artificial fly The first of these ways is called daping, dibbing, or shade fishing, and consists of using a long light rod with almost 2 yards of fine strong gut, to the end of which is tied a No. 7 or 8 hook, not too coarse in the wire. A fly, beetle, or insect of some kind is then put on the hook by transfixing the thorax of the insect. Then the angler, having watched the fish rising under some bank or projecting tree or bush, creeps very softly to the place, and, keeping himself out of sight, pokes the point of his rod through some open spot in the bushes, and allows the insect to drop on the surface, just over or a little above the spot where the fish he wants to catch has been rising. Probably he will not be able to see or to feel the fish rise, and he will have to trust to a third sense—his hearing. He will hear a slight "plop," like a bubble coming out of a submerged glass. A gentle strike then is required, and a tight hand on the fish, as such places are usually near old roots or boughs, in which the fish will try to shelter himself and entangle the tackle. The best fish are frequently taken in this way. Another method of using the natural fly or insect is by casting it. In this case a single-hand fly-rod is used, and it requires great care to avoid whipping the insect off the hook. Having cast the bait to the extent required, the line and bait rest on the surface, and the bait floats down quite naturally unchecked, and the fish rise at it in the ordinary manner. What is called the blow-line is another favourite method of using the live fly. A length of light floss silk is fastened on to the running line with about 2 feet of fine gut and a light hook at the end. Baiting the hook with a fly, the angler turns his back to the wind, holds the rod (a long light cane one) upright, allows the wind to blow the light floss line as far out as it will go, when he gradually lowers the rod and guides the fly till it touches the water a yard above a fish, when he floats over it. A little wind is required for this kind of fishing. Some insects, beetles, creepers, or larvæ of the stone-fly, &c., are used in mid-water, as already noted. A word or two as to the method: a couple of shots being fixed on the line, the bait is cast with an underhand swing, as in minnow fishing, up stream, and allowed to travel down towards where the angler stands. At every stop or check of the line it is necessary to strike, for the bait being tender, whether it be a twig, mud, or fish that arrests it, it will be spoilt; therefore the angler must always strike on every suspicion of a bite. For full particulars of this kind of fishing, as well as for all relating to trouting in the North British streams, the angler cannot do better than get *The Practical Angler*, by the late Mr Stewart, one of the best works ever published on such subjects. The best flies used for live-fly fishing are the large ones, as the green and grey drake, the stone fly, known often in Scotland as the May-fly, the big alder, the blue-bottle, and, indeed, any that are large enough. In casting them the angler must be careful to let his line make rather a sweep or circuit behind him, or he will easily flick off or destroy his bait. In using the artificial fly the angler employs either a single or a double handed rod,—generally he commences his apprenticeship with a single one. This is usually made either of hickory, green-heart, or split bamboo tied and glued up in lengths, runs from 10 to 12 feet long, and is tolerably pliant,—more or less so, according to the taste of the angler. The line used is generally twisted or plaited hair and silk, or fine dressed silk. The first is the lightest. A piece of gut, knotted together until it is about 3 yards long, is termed the casting-line, point, lash, or collar. This is fastened to the end of the reel or running-line, and to the other end of it is looped on an artificial fly. Sometimes two or more flies are used; in this case they are called droppers or bob flies, and are looped or tied on to the casting-line about 18 inches or 2 feet apart. The end fly is called the tail or stretcher. The best way of fastening on the drop flies is to whip the gut round with silk a few times, just above one of the knots, to prevent chafing; then take a fly with only about 5 inches of gut to it, tie a knot at the extreme end of the gut, and then knot on it once or twice, if required, over the whipped silk, and if the gut be moistened and drawn tight to the knot, even when only once knotted, it rarely slips, and the more it is pulled of course the tighter it gets. When it is desired to take the dropper off, a sharp knife slips off the extreme end knot, and the tie comes off easily. The loss of gut is infinitesimal, and the fly wears out before the gut is materially shortened. The angler having his rod and line ready, and his cast of flies selected, begins by letting out a little more line than the length of his rod, waves the rod back over his right shoulder, so as to extend the line behind him, and then, making a slight curve, impels it forward towards the point he desires to reach, letting it fall on the water as lightly as possible; then he allows his flies to float down the stream as far as they will go, when he draws out and repeats the cast, lengthening out line as he does so until he has as much out as he requires, or can cast comfortably. If in casting he does not make a curve with the rod-point behind him, but returns the line too directly, he will crack his fly off, or so crack the gut at the head of the fly that the first good fish will carry it away. When the angler sees a fish rise at his fly, if he is fishing for small fish, he cannot strike too quickly,—if for large ones, he may be a little more leisurely. In fishing over a fish that is rising, the best way is to cast a little above, and to allow the flies, with as little of the line as possible, to come over or past him. Some anglers fish up stream and some down. In fishing down stream the angler exposes himself more to the fish, and is more apt to miss his fish when they do rise; and if his tackle is fine and the fish heavy, having the weight of the stream against him is also more apt to break it than when fishing up; perhaps the best method is to fish diagonally up and across the stream. The angler pursues one of two systems. He either waits till he sees fish rise and fishes over them, wasting no time on intermediate water when he sees no rises; or he fishes the water out thoroughly, searching every hollow, bank, weed, and stone, that may hide a trout. In burn fishing for small trout the latter method is generally the one adopted. In larger rivers, where the fish are heavy and few, the former is more often preferred. When a good fish is hooked it will often resist strongly, and rush violently about, seeking to hide itself under weeds and roots, which are dangerous to the tackle. The angler must guide the fish as well as he can until it is tired, letting out line from the reel when resistance becomes too severe a strain on the tackle, and winding it in again when opportunity serves, but always keeping a tight line on the fish, as a slack line frequently loses it. When tired the fish should be towed gently to a favourable bank, and the landing-net quietly slipped under him. There must be no dashing or hasty movement with the net, lest the fish be frightened and make another effort to escape, as fish frequently do, and successfully, as it is a dangerous moment in the struggle. In fishing with a double-handed rod the rod is longer and the line a little heavier; in other respects there is no difference. The rod will vary from 13 to 15 feet for trouting. The left hand grasps it below the reel, and the right hand above; though, if the angler desires a change, or the necessities of the stream or wind require it, the hands can be reversed. The double-handed rod has several advantages over the single, having more power with big fish, and keeping the line and flies higher above obstructions.

The question of why fish take bunches of feathers tied on hooks, and what they mistake them for, has often been asked; and it is now pretty generally allowed that they take them for flies in the majority of instances, though in others they may mistake them for water-beetles, larvæ, or spiders, of which latter insect there are several that inhabit the water. Now, there are two classes of disputants on this matter: one which holds altogether to the fly theory, and therefore strives to imitate each fly that comes out closely; the other, which inclines more to the general insect theory, and merely gives a few flies of different colours, not caring to imitate anything in particular. Probably the best fishermen recognise both theories, but bind themselves exclusively to neither. But before entering upon the selection of flies it may be well to point out the difference in the practice of the north and south. We may, perhaps, take the late Mr Stewart[1] as the exponent of the north; and, perhaps, Mr Francis Francis[2] may be held as the latest exponent of the south. Mr Stewart gives a short list of a bare half-dozen of insects, three of which he calls spiders—black, red, and dun—and which are what are known in the south as "hackle" flies; that is, flies dressed with only a body and hackle.[3] The hackle is wound on round the hook, over the body, and is supposed to represent the legs of the fly, there being no wings. Mr Stewart also has three flies of three general colours, yellow, brown, and dark bodies; but as these may be varied with all sorts of wings and legs, the last may embrace in reality any number of flies which the taste of the angler may suggest. Mr Stewart's standards, however, are dressed thus:—(1.) A woodcock wing, with a single turn of a red hackle or landrail feather, dressed with yellow silk freely exposed on the body. For fishing in dark-coloured waters the fly may be dressed with scarlet thread. (2.) A hare-lug body, with corn-bunting or chaffinch wing. A woodcock wing may also be put on the same body, but should be made of the small light feathers taken from the inside of the wing. (3.) The same wing as the last, with a single turn of a soft black hen-hackle, or a small feather taken from the shoulder of a starling, dressed with dark-coloured silk. These, as Mr Stewart says, can be varied to any extent; but he pins his faith on those mentioned and the spiders: the black spider being a small dark starling feather wound over a brown silk body; the red one, the small feather outside the wing of the landrail, wound on over a yellow silk body; and the dun spider, the small soft ash-coloured feather from outside the dottrel's wing, with hardly any body but the tying of the hook. This is Mr Stewart's *repertoire*—it is not overburdensome; but in the south Mr Francis says that fish are much less numerous, and are larger and more critical, their feeding-time being much longer and food being more plentiful than in the north, and their taste, therefore, has to be more carefully considered; he therefore gives a list of flies for each month. Space does not permit us to name the whole of them, but we can enumerate a few of the best of them. The duns run through the whole year, and are therefore with the angler the *pièce de résistance*. These comprise varieties of the blue and yellow dun, and should be varied from the darkest slate-blue to the lightest shade yellow, from almost golden yellow up to the lightest fawn, almost a white, and these, slightly combined, go also to an olive. The earlier duns are the blue dun, which comes in in March, and is one of the best spring flies. It is in the water more or less throughout the season. Then there is the small dark iron-blue dun, which appears in April or May, with wings almost as dark as the body; and the bright yellow dun, with greenish-yellow body and pale slate-coloured wings. If these three be taken as the darkest of their class, and varieties, each of a shade or two lighter in colour, be made, they will take in the whole of this important class of flies. These duns are all imperfect insects, and have another change to go through before they are complete and able to propagate, and when they have completed this they usually die. The fly casts its skin and becomes a perfect insect, brighter in colour and more brisk in its motions. In this form they are called by the angler "spinners." Thus the blue dun becomes the red spinner, the yellow dun the brown spinner, the iron-blue dun the jenny spinner, and so on. All these flies belong, with several others, to the class or order *Neuroptera*, or nerve-winged flies—flies with clear gaudy wings, intersected with a network of veined markings. They form the most important order for the angler; but there is another order, the *Trichoptera*, or hairy-winged flies, which is scarcely less important, and which includes a very large number of flies on which fish habitually feed. These flies have soft feathery folding wings, which lie close on the back. They differ from the former order in having one less change to go through, for when they emerge from the pupa state and become flies, they are complete, and have no further change to go through. There are, besides these, which are flies born from water, other orders of land flies, imitations of which are used by anglers, as the cow-dung, hawthorn, and oak flies, the house-fly, &c., but they are comparatively insignificant,

[1] *The Practical Angler*. A. & C. Black, Edinburgh.
[2] *A Book on Angling*. Longmans & Co., London.
[3] The pointed feathers on a cock's or hen's neck are called hackles, but any small feather with a soft shortish fibre may be used as a hackle.

and with the exception of the cow-dung, which is a very useful fly, may be dispensed with. It is impossible here to give the dressing of the various flies; but if the angler goes to any respectable tackle-maker and mentions the names of the flies he requires he will get them. To commence then with the month of—

March, which is early enough for fly-fishing. The earliest fly found on the water is the February red. This, with the blue dun and the March brown, will do well during March, if anything will. The same flies kill well enough also in—

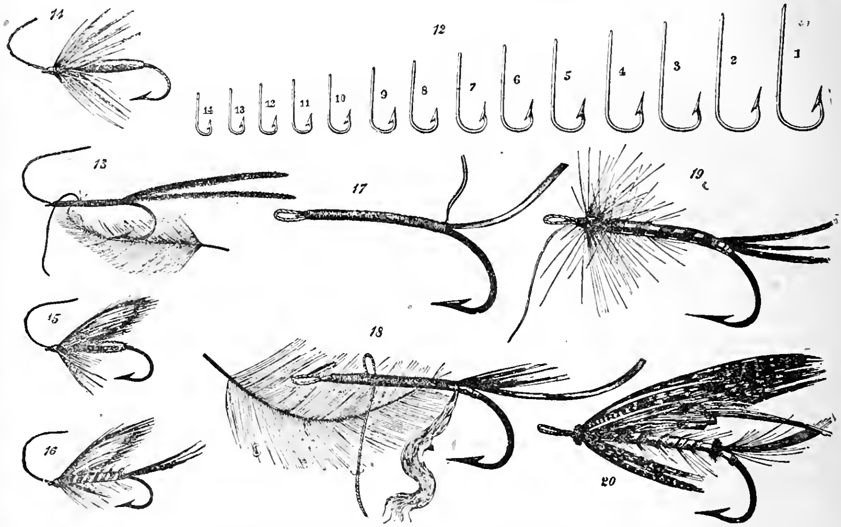
April, and to them may be added the red spinner, the cow-dung, the red and black hackles, the needle brown, and towards the end of the month, or entering on May, the yellow dun and the iron-blue dun.

May.—In addition to many of these, the angler may use the stone-fly, the sedge-fly, and the orl or alder fly—a very celebrated and general fly—with the little black gnat and the pale evening dun,—a fly which only comes on in the evening towards dusk, when the fish feed ravenously on it.

June.—In this month the standing dish with the trout in most rivers is the green drake, better known as the May fly, though it rarely appears until May is over. This and its transformations, the grey drake, with the well-known Welsh fly, the coch-y-bondu, otherwise the bracken clock, shorn-fly, &c.; these, with various light-coloured duns and spinners, may be used through the month with effect, as this is the prime month for fly-fishers.

July, as a rule, is rather an indifferent month. The weather is hot, the water low and clear, and fish do not feed well till the evening, when the white and brown moths may be used. In the day-time the red and black ant flies often kill well, and these, with various light-coloured duns and diminutive green, blue, and grey midges, must make up the bill of fare.

August.—The August dun and the cinnamon now are added to the list, many of the previous flies being still on.



September brings the whirling dun and the willow-fly, and this closes the angler's fly-fishing for trout.

In the latter months many of the earlier flies reappear, and with the list here given the angler should have no difficulty in killing fish anywhere. Most of the smaller trout-flies are dressed on hooks that range from the sizes No. 10 to 17 in the scale of hooks given in fig. 12 in the cut—the larger flies, as the May-flies, stone-fly, the moths, &c., running up to sizes 6, 7, and 8. There are, besides these flies, which are definite imitations of insects, a few of such general make and colour that though they do not strictly imitate one fly, may have a general likeness to several, and which are called general flies, and are often used when the angler is in a difficulty in knowing what to put on his cast. Among the best of these are the Hoffland, the Francis, the governor, the coachman, the soldier palmer, the wren-tail, the grouse and partridge hackles, &c. As a rule, the smaller flies are used in the day-time, the size being increased as the evening and night come on. In some waters, owing to the excessive fishing, the trout get so wary that after the May-fly there is very little chance, unless the day be particularly favourable, of hooking a trout before the evening, and fishing is often carried on till ten or eleven o'clock at night. Of course at such times the angler has to trust more to his senses of feeling and hearing than sight. In the majority of instances it is the custom to let the tackle soak, and when fishing to allow the fly to sink a little under the surface—to fish with a "wet fly," as it is called; in others, where the fish are more wary, in order to imitate nature more closely yet, it is the custom to fish with a dry one—that is, to make the fly and line rest on the surface, without becoming submerged. To this end, when the fly and line become wet, they are waved to and fro from the rod point in the air to make them become dry again. The fly should always be allowed to float down stream, as natural flies do, and should not be jerked or "played," as it is termed, unless the angler is fishing down stream and drawing his fly against it, when he will allow it to sink under water, and in that position it may be supposed to represent some quick darting larva. So far, stream fishing only has been dealt with.

Lake Fishing differs in its practice materially from stream fishing, and though some flies which are used on streams will also kill on lakes, yet, for the most part, there is a fancy *repertoire* in this respect which differs wholly from that employed in streams. Lake-trout flies, particularly in Scotland, are made with wool bodies, the prevailing colours being red, claret, orange, yellow, green, and black, with a light spiral up the body of gold or silver tinsel. The hackles are chiefly either black or red, or red with a black centre; the wings are either of teal, mallard, or woodcock. Here and there the white tip feather in the drake's wing is a favourite wing for flies. They are usually dressed on 7, 8, or 9 hooks; the same flies a size or two larger do equally well for sea-trout flies.

Lake-trout fishing is conducted either from a boat or from the shore. The best depth of water in which to fish for trout varies from 6 or 8 to 12 or 14 feet, and between these depths the best sport is obtained; and the angler should therefore fish over them for choice, though occasionally fish may be caught in both deeper and shallower water. In lake fishing it is always desirable to have a good ruffling breeze, as the fish do not rise or take well in a calm. The best places are in sheltered bays, by rocky points or islands, or where burns flow in; drifting along by these, and casting ahead and shorewards, the angler watches every break in the water. While drifting along in his boat, it may happen that, the wind being high, he drifts too fast to fish thoroughly and properly over the ground. To obviate this a stone or an anchor is cast over and allowed to drag along the bottom, so as to check the way of the boat, and to give time to the angler to fish. A good boatman and netsman is here a great desideratum, and much of the chance of sport depends upon him. The great fault of most boatmen is that they go too quickly over the casts; and it requires a man with a knowledge of the lake, as well as experience in managing the boat, so to conduct matters that the angler has the best chance of sport. When rowing to his ground, or from point to point, the angler should always put out the spinning minnow, and thus he may take one or two of the best fish. As fish do not always lie in the same places, wind and weather have to be sedulously consulted. In fishing from the shore the angler seldom gets the best sport, and often has to wade to reach fishable water, while the best casts are often beyond his reach; and therefore, whenever a boat can be employed, it is to be preferred for lakes.

Salmon Fishing.

The salmon is the noblest and strongest fish on which the angler essays his art, and fish from 40 to 50 lb in weight, and sometimes of even more, are occasionally taken by the rod and line; though for the ordinary pur-

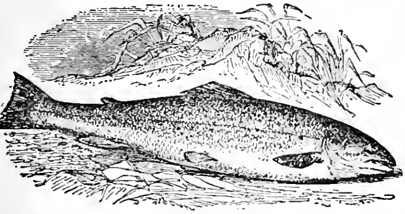


FIG. 21.—The Salmon.

poses of sport, fish from 7 or 8 lb up to 20 are far more generally taken. When a salmon in good condition is first hooked he makes a strong and violent resistance, dashing through the water frequently for a distance of 60 or 70 yards or more at a time, and compelling the angler to let so much line off the reel; springing out of the water, often to a height of several feet, several times during the struggle; and finding that force is unavailing to break the line or withdraw the hook, he will often have recourse to cunning, and cut the line or rub the hook out of his nose against some rock; or, hiding himself at the bottom behind big stones and boulders, he will sulk and remain immovable for a long time. Occasionally he will run up or down rapids or falls in his terror and rage. To control all these vagaries, to combat his cunning, the angler, with his bending rod and practised skill, lets him take out line when his struggles are dangerous, cautiously winding it back again when he is able to do so safely, and thus keeping a certain strain upon the fish he gradually tires him out and wears his strength down, and at last, when unable to resist any longer, he is led in towards the shore, where upon some convenient rock or strand the attendant gaffsman stands or crouches, with a sharp-pointed steel hook attached to a short ashen staff called a gaff, waiting his opportunity. As the salmon is led past or near him, almost on the surface of the water, the hook is extended beyond the fish, the gaffsman makes a short sharp stroke with it, and digging the hook into the side of the salmon, with a sudden and instantaneous pull drags it out of the water to the land; a rap on the skull from a stick or stone terminates the poor salmon's life, and henceforth he becomes mere provender. Sometimes a large landing-net is used to land the fish, but though this prevents the spoiling of a portion of the fish by avoiding the need for making a hole with the gaff, it is less convenient and of more risk to the safety of the fish. The most favourite plan of fishing for salmon is with the fly, though in many places they will also take both worm and minnow freely, and are thus fished for. The salmon-fly is a most wonderful conglomeration of feathers, silks, and tinsels, and oftentimes is as brilliant as the most glittering humming-bird. What the salmon mistakes it for is not easy to say, for there is nothing like it in nature. Probably a semi-transparent shrimp or prawn reflecting the gorgeous tints of the surrounding sea vegetation may be the nearest approach to it. The manufacture of the salmon-fly is given hereafter. They are made of various sizes,—the longest for the early spring when the rivers are much swollen and very turbid, when hooks of 3 inches in length, and sometimes even longer, are employed; and from this extreme size they diminish gradually to a large sea-trout size, which is about in accordance with the hooks numbered 6 and 7 in the scale given in the illustration. These are used when the rivers have sunk down to their summer level, and are very clear and still, and the flies in the intervening sizes are carefully adjusted to suit the size and clearness of the water. There is a great difference in the method of using the trout and the salmon fly. In salmon fishing there are certain spots in the river upon which salmon are known to rest and to feed, and these are called salmon-casts, throws, lodges, or stands. They may be but a few yards in length, and comprise a favourite ledge, or a rock or two, behind which salmon like to shelter,—for a salmon always has his lair or resting-place behind some projecting rock or stone; or they may extend for 100 or 200 yards, or even more. There are, too, in many rivers plenty of places where salmon may be seen sporting and jumping about, but where, owing to the depth of water or some other reason, they never feed or at least take the fly. The angler, therefore, who knows thoroughly the cast he is about to fish, has a great advantage, for he knows where the big stones and the particular eddies are in which a salmon may be expected to rise, and how the fly should be drawn over the fish so as to show itself in the most tempting manner; whereas the angler who has not much knowledge is often apt to dwell upon spots that are comparatively barren, and to pass quickly over those that would perhaps repay particular attention. In fishing a cast, the angler casts diagonally across down stream, and draws the fly up stream towards him, softly raising and lowering the top of the rod so as to check and loosen the fly alternately, and to make all its fibres open and shut so as to counterfeit life. When a salmon rises to the fly he either makes a big bulge or boil in the water, or, if he is unusually eager, he throws his head and half his body above the surface, rolling over like a porpoise in his endeavour to seize the fly; but a salmon very often misses the fly in his eagerness, and when he does, the very worst the angler can do is to pull it away from him, as after such a miss it is not at all uncommon for a salmon to turn round hastily and to make a second snatch at the fly, which he then rarely misses; but if the fly is whipped away from him, he is frightened and disgusted, and goes down sulkily, refusing to rise again. It is therefore the safest plan to wait till you feel your fish, and then to strike, and even then it is not desirable to be too rough. A violent stroke is not the best one,—a slight elevation of the rod so as to fix the point, and then a steady strain, enough to force the barb of the hook home in the next minute, is the best way of getting a firm hold. Many fishers strike the moment they see the boil of the fish, under the belief that the boil is made by the tail of the salmon as he turns to go down, and that they do not see him till he gets the fly in his jaws. This is true, provided he does not miss his aim altogether; if he does (as he certainly often does, for it must be remembered that the fly is constantly in motion, which of course renders it not very easy to see), then to strike is to pull the fly away and to deprive the salmon of another chance. When he has hooked a fish, the angler should look round and study what dangers there are which may prove destructive to his hopes, and determine if possible so to manage his fish as to avoid them. He must, therefore, always retain his coolness and presence of mind; flurry and confusion are often fatal to success. If a salmon jumps out of water the point of the rod should be lowered, so that the line be slackened, for if it be tight the sudden weight is apt to pull it out of the fish's jaw. If he sulks, the only way is to frighten him out of his hole by poking a long pole into it, or by throwing stones, or by some other device. If he runs for the edge of a fall or rapid, it is often a very good plan to let out a lot of loose line, and the salmon, fancying himself free again, will not go over, but will head round and face up stream again. As the devices of the salmon to escape are numerous, they cannot be dealt with fully here. No two salmon-casts are alike, and therefore no two can be fished in the same way; each one must be fished to suit the particular capabilities it possesses.

The method of casting the salmon-fly is similar to that adopted with the double-hand trout-rod; the only difference being that the rod is larger and heavier, running up to 21 feet, and even more sometimes, and seldom less than 16 or 17 feet. The line is stout, well-dressed. 8-plait silk; the casting-line a yard or two of treble-twisted gut, and a yard or two of stout single salmon gut. Having mastered his rod well, the angler will find it comparatively easy to cast up to 20 yards of line; from this up to 30 yards every extra yard he can throw proves him more and more a good fisherman, while every yard he can cast beyond 30 shows him to be a master of his craft. The angler should never cast more line out than he can work and fish comfortably; if he does, he has a slack line when he requires a tight one, and he will often raise and scratch fish, and spoil his own sport and other people's, when a yard or two less of line would have enabled him to catch his fish. Very long throws are only necessary under unusual circumstances; 25 yards will generally cover fully all that the angler really needs to fish.

Salmon-Flies.

We may give a short list of general salmon-flies such as the angler will find it useful to have always by him, and which he can employ if he does not know the general flies used on the river, and every river has some pet fly, some different combination of feathers and fur from its neighbour. The flies given are all standard flies, and may be had at any respectable tackle-maker's. The method of dressing them is the one which experience has shown to be the best for attracting the notice of the salmon.

The Claret.—One of the most useful general flies. Beginning the dressing at the bend of the hook, which is the tail end of the fly, a turn or two of gold twist and golden-coloured floss silk is taken for the tag; above this is lashed on a tail formed of a golden pheasant topping and some strips of blue and red macaw. Over the stump of the tail is fastened the but, a sort of ruff made of two or three turns of the herl or strands of a black ostrich feather. Then comes the body—first three turns of orange floss silk, then reddish claret pig's wool wound on to the top of the body; over the wool spirals of stout gold thread; and, beginning halfway down the body, a hackle of reddish claret to the shoulder, and at the shoulder two or three turns of black hackle. The wing is made first of tippet feather of the golden pheasant, which forms a sort of short under wing; above that is a mixed wing of fibres from the golden pheasant tail, turkey, bustard, and peacock wing, with a few fibres of green and red parrot; above all a single topping, with a rib to either wing, of blue macaw fibre,—the head of the fly being black, either ostrich, herl, or chenille. This fly may be used of various sizes, and is a very general favourite in most waters.

The Black and Teal.—Another very general favourite, the leading points of which are a black body with silver spirals of twist or tinsel; a single topping for the tail; black hackle up to the shoulder, over which either a teal feather or a gallina feather (with the large spots), and a wing of teal or rather pintail, and over it two jungle cock feathers with or without a topping. This fly also may be used of all sizes; dressed small, it is good for either lake or sea trout.

The Blue Doctor.—Tag, a few turns of fine gold twist; tail, a topping; but, scarlet crewel or wool; body, pale blue floss silk, with a hackle a shade darker, or a blue jay's feather; silver tinsel (in large flies with silver twist beside it); grouse, partridge, or bustard hackle at the shoulder; a blue jay feather or blue hackle over it. The wing is mixed of fibres of the bustard, dark turkey, argus pheasant, claret, blue, and yellow fibres of dyed swan; sometimes a topping over all and a head of scarlet crewel.

The Silver Doctor.—Also a very great favourite. Tag, silver tinsel; tail, a topping; but, a turn of red crewel; body of silver tinsel entirely; hackle, blue, with brown hackle at the shoulder, and a small speckled gallina feather hackled on over it; wing chiefly pintail, with a few red and blue fibres and a topping; head, red crewel.

The Butcher.—A very killing fly, and generally used. Tag, gold twist and dark orange floss; tail, a topping; but, black ostrich herl; body, two or three turns of scarlet. The same of a medium blue, then of red, and lastly of dark blue pig's wool; broad silver tinsel; a medium red claret hackle with a gallina at the shoulder; under wing a tippet and rump feather of the golden pheasant, and over them strips of brown mallard, bustard, or peacock wing.

The Parson.—If a gaudy fly is required, there are few more showy ones than this. Tag, silver tinsel and mauve floss; tail, two toppings, a few sprigs of tippet, and a green kingfisher feather; body, two turns of gold floss silk, golden pig's wool merging into orange; silver twist; golden orange hackle, red orange hackle above it; three or four short toppings tied on at the breast; wing, a tippet feather of the golden pheasant, a strip of pintail on either side, seven or eight toppings, and a couple of kingfisher feathers at the shoulder on either side; black head. A more subdued parson may be made by using a jay's hackle at the shoulder instead of the short toppings, by reducing the number of toppings in the wing, and adding some darker fibres of golden pheasant tail, bustard, &c.

The Drake Wing.—Tail, tippet sprigs and a yellow toucan feather; body, orange red and black pig's wool; silver tinsel; hackle, a coch-y-bondu stained of a dark orange red; a lavender hackle at shoulders; wing, two strips of drake or pintail. Bodies of orange, claret, dark blue, and black pig's wool graduated up to the head, are very great favourites, and, wedded to various hackles and wings, kill extensively.

The Orange and Grouse.—Flies with orange or golden floss silk bodies, and various hackles and wings, also kill widely. The above fly is tied with a tag of silver tinsel. Tail, a topping and king fisher feather; but, black ostrich herl; body, three turns of magenta floss, and the rest of light orange floss; hackle, grouse with the tips snipped off—not on the back—with three or four toppings over the long grouse fibre for wing; blue jay tied sparely at the shoulder; blue macaw ribs; a black head.

A very good series of plain flies, very much used, can be made thus:—Tag, two turns of tinsel; tail, a topping and some tippet sprigs; body, a turn of bright orange brown followed by yellow in the centre, and the rest of lightish blue pig's wool; a broadish silver tinsel, the wool rough and picked out, with a black hackle, and wings of peacock wing, sometimes with a tippet in the centre or a topping over. By varying the wing or hackle, a very taking series of flies can be had.

With this list of flies the angler ought to be able, in default of knowing the special flies suited to the river, to fish any river with confidence, and, if the fish are in the humour to rise, to get sport in it. The colour, and particularly the size of the fly, are things to study in catering for a willing salmon. Too large a fly often causes a false rise; when this is found to occur, the size should be reduced.

Sea-Trout Fishing.

Next to the salmon ranks in value for sport the sea-trout. Of these there are two kinds: 1st, The salmon-trout (*Salmo trutta*); and 2d, The bull or grey trout (*Salmo eriox*). The former is much the better fish for sport and for the table, the latter being coarser for the table and rather shy of the angler's lures. Sea-trout abound in several rivers in the north, and many are taken in the tributaries of the Tweed and other northern rivers; but they are perhaps more abundant and show better sport to the angler in some of the western Irish waters. The salmon-trout usually average below 4 ℔ each, perhaps from 1 to 2 ℔ being the prevailing size, though now and then much larger fish are taken. The bull-trout often runs up to a far greater size, and fish of above 20 and even up to 30 ℔ are not very uncommon. The salmon-trout, called in Ireland the white trout, and on Tweed and the northern rivers the herling or silver white, is a smart, bold-rising fish; it takes freely at times, and plays with wonderful agility, frequently when hooked springing from the water like an acrobat many times in succession, and trying all the angler's skill to bring it into the basket. In lakes they frequently abound in profusion, and a hundredweight of them, and sometimes more, are or have been often taken in one day. The tackle, of course, is lighter than that used for salmon, and somewhat heavier than is used for the common trout. The flies are also of a size between those used for the other two; bodies of claret, yellow and orange, green, blue, and black, either of silk or fur, are the favourites. In Ireland they prefer a mixed wing, chiefly made up of fibres of yellow, red, and green parrot, with bustard and other dark feathers; the hackles being suitable. In Scotland they prefer plain wings of drake, teal, woodcock, and the black and white tip from the wild drake wing; but the fashion of the dressing is not a very important matter, so that the colour is right. At times sea-trout rise very badly, and the angler will get a number of rises, but succeed only in hooking a very few fish; but when the fish are taking well, few branches of the sport show better amusement than a day's sea-trout fishing. They also, unlike the salmon, take a spinning bait well while still in the salt water, and many are thus captured in the estuaries and salt-water lochs of Scotland while they are making their way to the mouths of the rivers up which they eventually would run to deposit their spawn.

Trout Fishing.

The trout (*Salmo fario*) has already been fully dealt with as regards the means employed in capturing him, and very little more needs to be said. He may be caught on the surface by the natural and artificial fly, by spinning a minnow, &c., in mid-water, by a live minnow, by casting a beetle or grub also in mid-water, and by fishing with a worm at the bottom. There are very few fish that have so wide a range as the trout. From the poles to the outside boundaries of the tropics they are found on every continent, either in running or still waters, for neither comes amiss to them. From the huge lake trout, vying with the salmon in size and strength, the species dwindles down to the

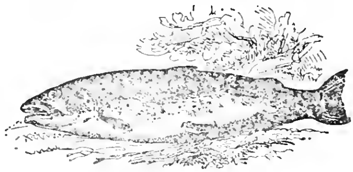

FIG. 22.—The Common Trout.

small burn fish of six or eight to the pound. There is hardly any way of using the rod that is not more or less suitable for their capture; and though salmon fishing is held the nobler pursuit of the two, yet far more skill is required to make an expert trout fisher, so cunning and wary do they become when much fished over.

Greyling Fishing.

The greyling (*Salmo Thymallus*) is not so widely distributed as the other members of the Salmonidæ. It is found in comparatively few rivers in England; in only one in Scotland, the Clyde, into which it was introduced some years ago; and not at all in Ireland. It is a useful fish for the angler, inasmuch as it comes into the best rivers just as the trout is going out. It is a handsome fish, of graceful shape, very silvery sides and belly, with small black spots. It supposed to smell of thyme when first caught, hence its name. It is seldom known to run much above 4 ℔ in weight, and even that size is not at all common,—from ½ or 1 ℔ to 1½ ℔ being the average takeable size. It rises very freely to the fly, and will take other bait; but is less carnivorous than the trout, so that minnow is rarely used as a lure for it,—small insects, as gentles, caddis, &c., may be used with advantage. The flies it prefers are usually small bright duns and spinners, such as are used for trout in clear waters. The longer dorsal fin of the greyling allows it to rise from greater depths more rapidly than the trout, and deep still reaches often hold the best fish. Unlike the trout, a greyling will often rise and refuse the fly four or five or more times in succession, and yet will perhaps take it after all. The mouth being tender, the fish must be treated more gently than the trout, or it may break away. There is one way of fishing for greyling practised in the midland rivers which is worth notice. It is called "grasshopper fishing," though the lure is totally unlike a grasshopper. A lump of lead of an elongated pear shape is welded or cast on to the shank of a No. 5 or 6 hook. This is covered with wool or worsted wound on to it in rings of different colours—green, yellow, and sometimes red. To make the bait more attractive, sometimes two or three gentles are put on the hook, and the bait is cast into a greyling eddy, and worked up and down smartly until taken by a fish. The angler strikes at every suspicion of a bite. Large baskets of greyling are taken thus.

Roach Fishing.

The roach (*Cyprinus rutilus*) is caught principally in bottom fishing with the float, as before described. The roach has been termed the river sheep, from his supposed unsuspiciousness of guile, but that can only be when he is never fished for. About London, where he forms a great attraction to a numerous body of anglers, he is particularly sharp; and nothing but the finest tackle, such as a single almost colourless horse hair, will take him, even gut being refused when he is much fished for. A very light quill float and a few sinkers are desirable. Roach weighing 2 ℔

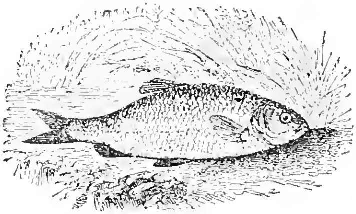

Fig. 23.—The Roach.

are not at all common, from 1 ℔ to 1½ ℔ being the usual limits. The best hook baits for roach are gentles, greaves, red worms, a plain paste made of flour and water or worked up bread crumb or pearl barley. Of course there are a multitude of other baits which are sometimes preferred, but these will rarely fail if the fish are at all inclined to feed. The best general ground-bait is that already mentioned in bottom fishing, though all sorts of other matters—as grains, barley-meal, pollard, boiled wheat, &c.—are sometimes used. Roach, when feeding near the surface, will sometimes take a fly, as indeed will most fish. Size of hooks required, 10, 11, and 12.

The Dace.

The dace (*Cyprinus leuciscus*) is frequently found in common with the roach, though often abounding in trout streams. Where there are no roach, it takes the same baits as the roach in all respects, save that it runs much more freely at the fly. In the months of July, August, and September on the Thames, large numbers of dace are taken with the fly from the water between Isleworth and Teddington with small black and red palmer and other flies tipped with a gentle or a piece of wash leather in imitation, and it is not uncommon for an angler to take ten dozen of them in a tide. The dace runs quickly, and requires very quick striking. The Jews are very fond of dace for their feasts, and pay a high price for them. Size of hooks required, 10, 11, and 12.

The Chub.

The chub (*Cyprinus cephalus*) is perhaps the least valuable fresh-water fish for table purposes, though probably the barbel may almost be put on a level with him, albeit Izaak Walton contrived to make a tasty dish of it; but at best the flesh is rather vapid, watery, and abounding in

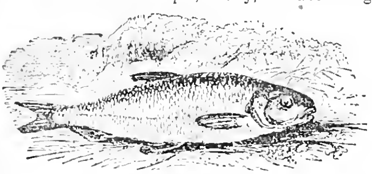

Fig. 24.—The Chub or Skelly.

bones. It is a fair sporting fish, however. In addition to his taking all kinds of baits in bottom fishing, he will take both natural and artificial insects on the surface boldly, and many are taken by dressing a cockchafer, humble bee, or small frog, or by casting imitations of the same, artificially prepared, under the boughs where the chub lies waiting. A big artificial humble bee or cockchafer, or a fly made of a silver tinsel body, coch-y-boudu hackle and turkey wing, with sprigs of green peacock in it, are about the three best lures for him, though many prefer red and black palmers. The chub often lies also in deep heavy streams, and will frequently in such cases take a live or a spinning minnow pretty freely. Among bottom baits cheese and greaves are special favourites. The chub rarely exceeds 6 or 7 ℔ in weight, though specimens have been known to attain 9 ℔. Size of hooks, 3, 4, and sometimes larger.

The Barbel.

The barbel (*Cyprinus barbus*), so termed from the wattles or beard depending from the sides of the mouth, is a very game fish for the angler, frequenting deep and rapid streams, and often turbulent and broken waters, as at the tail of mill wheels, weirs, &c. They go in large shoals, so that when the barbel are got upon the feed the angler often takes from 20 to 50 or more in a day. They require a good deal of ground-baiting, however,—worms, gentles, greaves, &c., being often used in large quantities two or three nights before fishing to induce them to feed freely, and even then the angler is as likely as not to be disappointed. A clean red lob-worm is, upon the whole, perhaps the best bait for a barbel, and next to that a bunch of gentles or greaves, though they will sometimes take freely a number of things, including fat bacon and raw beef. They are fished for in several ways by the ordinary and travelling float method, by the ledger and the clay-ball principally; and it often happens that they will take pretty well in one of these ways and refuse the others. The barbel nibbles a little at the still bait before biting, but when a good double tug is felt, the angler may strike firmly. Owing to its great expanse of fins, and its rounded body, the barbel is a very stout fighter, and makes a most prolonged resistance; and though it is not so active as either salmon or trout, it is more troublesome, and takes longer to subdue. In the spring months the large barbel will frequently take a spinning bait freely, and when spinning for large trout in a weir the angler frequently receives severe disappointment by hooking a big out-of-season barbel. They run up to 16 ℔ weight, but one of 12 ℔ is not caught every day. On the Thames the average is from 1 to 4 ℔. They are a very curious fish, some years biting freely, and during others hardly at all. Size of hooks for worms, 1, 2, 3; for other baits smaller.

The Bream.

The bream (*Cyprinus brama*). It is said that there are two kinds of bream,—the small white bream (flat) and the big olive-coloured bream. Much that applies to the barbel applies also to the bream. The same baits and the same

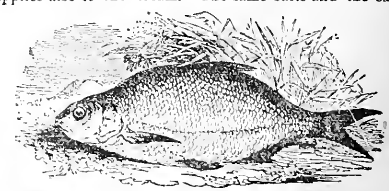

Fig. 25.—The Bream or Carp Bream.

methods of fishing must be adopted, but if possible finer tackle is required. Perhaps if there is one bait the bream likes better than another, it is two or three brandlings or red worms stuck on the hook. Otherwise his taste resembles the barbel's. Barbel and bream are commonly caught in the same swim, but bream like to have a deep quiet eddy to lie in. They are a curious fish, suddenly appearing in places where they have never been seen before, and after stopping for a year or two, as suddenly disappearing. They run up to 7 lb, and in the Thames average from 1 lb to 4 lb. They are a very fair fish for the table, and fry well. Size of hooks, 4, 5, 6.

The Carp.

The carp (*Cyprinus carpio*) is described by the Dame Juliana Berners as a "deyntous dish." Unfortunately the decline of knowledge in the matter of fish feeding and rearing in ponds, &c., renders it difficult to realise the dame's assertion, an ordinary carp from an ordinary pond being poor in flesh and muddy in flavour, but it is quite possible that the flesh, which is so susceptible of taking the nasty flavours exhaled around it, would, under better management, with better food and purer water, be both delicate and "deyntous." Of all fresh-water fish, the carp is one of the most cunning and difficult to catch where he is much fished for, though, singularly enough, they take much better in rivers than in still water. In still water, even if you can induce a good carp to pay attention to your bait (which you cannot always), he will nibble, and turn it about, until he either sucks it off the hook without touching the hook, or he discovers the hook on the line,

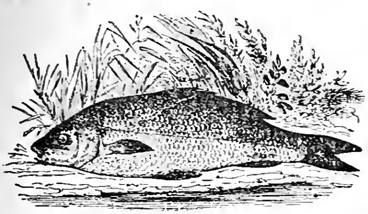

Fig. 26.—The Common Carp.

becomes alarmed, and swims away. Very fine tackle, therefore, is required in carp fishing; but as he is big and lusty, it should be round and strong. There are various baits which more or less attract him. Paste sweetened with sugar or honey is one of the best; but he will at times take gentles, greaves, and red worms. Some affect boiled green peas, some beans, and many are taken with parboiled potato, which is one of the best of baits in some places for large fish. The best ground-baits are those recommended already, of bran, rice, bread, &c. If the fish are very shy, float tackle is to be avoided, and a very light ledger on a pistol bullet used instead. As the line rests on the ground, the carp does not see it, and takes the bait without suspicion. A clear bottom, however, is desirable. Carp run up to a heavy weight, sometimes between 20 and 30 lb, and they live to a great age. Size of hooks, 5, 6, 7.

Tench.

The tench (*Cyprinus tinca*) very much resembles the carp in his habits, feeding on much the same matters, though neither paste nor any vegetable baits are to be recommended for tench. The best bait that can be put to him is a red worm, or two or three gentles; and for ground-baits, chopped worms and gentles are preferable. Tench bite best in the morning and evening, when there is hardly light enough to see the float; for float tackle is best for the tench, though he nibbles and mumbles at the bait exactly as the carp does and often, like him, leaves it after nibbling off all the tail of the worm that is beyond the point of the hook. When the tench is so shy his eagerness may be stimulated by very gently drawing the float and bait away a few inches, when he will often rush at the bait and seize it at once. Tench are a very quiet, unobtrusive fish, and may exist in a pond for a long time

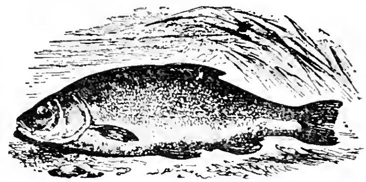

Fig. 27.—The Tench.

without being known to be there. They are very capricious in biting, sometimes biting well for a day or two, and again refusing all baits for weeks without any apparent reason. If taken from clear waters, the tench is a very good table fish—second only to the eel. Size of hooks, 6, 7, and 8.

The Eel.

The eel (*Anguilla acutirostris*). The eel is scarcely an angler's fish, but it is often taken in angling, and it is a most excellent and luscious table fish. It takes various baits, as worms, small dead fish, which are the best for it, and takes them better when they are still than when moving. Thus, night-lines are the best way of capturing the eel. Occasionally float tackle is used for the purpose, when the roughest tackle, with a float-hook and worm, suffices. Sniggling for eels is an amusing way of taking them. A stout needle, lashed to a long string, is concealed in a worm; the point of the needle is stuck lightly in the end of a long stick. This is then introduced into the mouth of a hole in which an eel is supposed to shelter. As soon as the eel sees it he secures it, pulls it from the stick, and devours it. The string is lashed to the middle of the needle, so that when the angler pulls at it the needle turns crosswise in his gullet. The angler pulls with a steady strain at the line, until at last the eel, unable to resist longer, comes out and is caught. Clotting for eels, by means of a big bunch of worms strung upon worsted and gathered up into festoons, is another way. The eels entangle their teeth in the worsted, and are lifted out and dropped into a pail. A hundredweight in a night has been caught in this way. They are chiefly caught, however, by baskets, nets, or traps set in mill-weirs, when they are migrating, and in some places, at such times, tons of eels are caught in a night. Fresh-water eels run up to a large size. They have been known to exceed 20 lb, but 4 or 5 lb are more common, and the average is from 1 to 2 lb. Hooks any size that is suitable—from 4 to 8.

The Gudgeon.

The gudgeon (*Cyprinus gobio*) frequently forms the young angler's first quarry. This little fish abounds in large shoals in the Thames and other rivers, six or seven dozen, or even more, frequently being taken at one pitch. No ground-bait is required to attract them, but the bottom being disturbed and harrowed by a heavy iron rake, the fish flock to the spot to search for food in the *débris*, and they will continue to bite for some time, when another rake renews their avidity. A light cork float and a small 10 or 11 hook, with a fragment of red worm, is all that is needed: for so eager are the little fellows, that they pull the float down with a dash, so that the angler rarely misses his prey. A dish of gudgeons, gently fried, crisp and brown, is by no means to be despised. With the gudgeon the pope, or ruffe (*Perca cernua*), is often found. It is little worth for the angler, and is not very abundant. All that applies to the capture of the gudgeon applies to the pope. The bleak also (*Cyprinus alburnus*), a lively little fish, but hardly worth the angler's notice; it may be taken either with bait or fly, as is the dace.

The Pike.

The various methods of fishing for the pike (*Esox lucius*) have already been detailed—spinning, live baiting, paternostering, the live and dead gorge, being the principal, though the pike will take a big fly at times made of peacock's feathers and other showy matters. Pike grow to a very large size, where the water is favourable even to 70 or 80 lb; but pike of half that weight are not common, and one of 20 lb is a prize to a London angler.

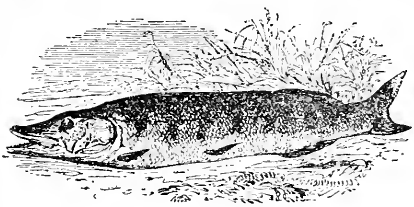

Fig. 28.—The Pike.

The Perch.

The perch (*Perca fluviatilis*) has also been partially dealt with, paternostering being about the best way of taking perch, though at times a float and worm will take better still, and even the ledger will take them. In big rivers perch in the winter get into the eddies and stiller waters, out of the floods, in shoals, and here, as the water begins to clear, they may be taken to the number of several dozen; often two or three at a time. They are excellent fish for the table. They run up to 4 lb weight, though heavier ones are sometimes taken. Hooks, 4, 5, and 6.

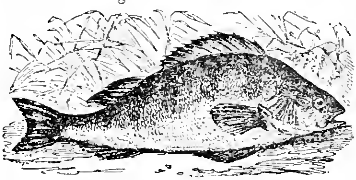

Fig. 29.—The Perch.

On Tackle and Fly-Making.

It is exceedingly desirable that the angler should be able to make and repair his own tackle. This will probably save him quite one-half of his outlay, and has the satisfaction of knowing that he can trust to the tackle, which he cannot always when he buys it; while, in case of accident, he can repair without delay, when the impossibility of doing so might peril his day's sport. The art of tying strands of gut together and of whipping on a hook may be learnt in a minute; and there is scarcely a book on angling that does not thoroughly explain it. Fly-tying, however, requires more notice.

The simplest form of trout-fly is the hackle, or palmer-fly. Having whipped the gut on to the hook with strong but fine silk, finishing at the bend of the hook, take two or three strands from the peacock's tail, known as harls, lay the ends together at the bend of the hook and whip them on with the silk, wind the silk on two-thirds up the hook, and then tie on the tip of a cock's hackle. Fig. 13 (page 38) shows the position. Should it be desired, however, to run the hackle all over the body, it may be tied on along with the peacock's harls. In that case, first wind on the harls round the hook side by side, avoiding the hackle, until they reach the head of the hook, when they must be tied down and cut off; then wind the hackle on likewise up to the head, pressing it down so as to make the fibres point all towards the tail; and having reached the head, tie that down too and snip off the waste, when fig. 14 is finished, and the hackle or palmer-fly complete (see fig. 14). If it be required to produce a winged fly, a little less hackle must be employed, and two slips of some suitable feather placed together as a pair of wings, and whipped on as in fig. 15 (see fig. 15). Should a tail be desired, two or three wisps of some suitable feather are whipped on at the bend of the hook before tying on the harls, and if tinsel be needed, that is tied on with the harl, and wound on over the body. Fig. 16 shows the complete fly, with tail, tinsel, and all complete. Various matters are used for bodies, as silk, wool, fur, &c. How to put on fur will be told in tying the salmon-fly.

The method of tying a salmon-fly is rather more complicated than that used in the trout-fly. Take a short piece of twisted gut or gimp, double it and lash it on so as to leave an eye at the head, as in fig. 17 (see fig. 17); then take a short fragment of tinsel or twist, and tie it on as shown; wind this round the bend of the hook two or three times; this forms the tag, and may be seen complete in fig. 18 (see fig. 18); over this tie on the tail, composed of fibres or a topping, &c., also shown in fig. 18[1] (see fig. 18); then tie in the silk or wool, or whatever the body is made with, also the tinsel, if needed; having tied it in, carry the silk on until the spot where the hackle is to commence is reached, then tie that in, and work the silk on to the shoulder. The result of these preparations is shown in fig. 18 (see fig. 18). Then wind on the silk or wool body evenly until it reaches the shoulder, when fasten it off; next, wind on the tinsel in even spirals, and fasten that off in the same way; next, the hackle, which may be stripped on one side, if it be required, thinly, or prepared by pressing the fibres together, so as to make them point as far as possible in the same direction. Having fastened off the hackle, the fly appears as in fig. 19 (see fig. 19). Then having carefully left a bit of the hook for the purpose, tie on the wing, which is composed of fibres or strips of feathers laid together. This is a nice operation, and requires a delicate but firm hand. After this, if it be needed, a head can be wound on over the stump of the wing, and for that purpose a fragment of chenille is the best substance. A few turns of the silk fixes the loop and finishes off, and a touch of varnish secures it. The complete fly is shown in fig. 20. In using fur or pig's wool for a body, the long coarse fibres should be picked out and rejected; the rest should be pulled into fragments, and then laid in a small ridge along the palm of the hand and rolled over and over, as cigarette makers do their tobacco; and having obtained sufficient coherence, it should be laid along the silk, and the silk being twirled round rapidly, is incorporated with the fur, which can then be wound on the hook to form the body of the fly. Various colours may thus be employed in the same fly. (F. F.)

[1] Some flies have over this a couple of turns of ostrich harl or other feather, which is called the but. It is not necessary, and serves no purpose, but it is shown in the complete fly in fig. 20.

ANGLO-SAXON LITERATURE. See ENGLISH LITERATURE.

ANGLO-SAXONS. See ENGLAND.

ANGOLA, a name that is employed to designate at least three different, although partly coincident, portions of the west coast of Africa. It is often applied to the whole coast-line, from Cape Lopez de Gonsalvo, in lat. 0° 44′ S., to St Felipe de Benguela, in 12° 24′ S.; the Portuguese consider that the entire country lying between the Zaire or Congo and lat. 18° S., and stretching for a considerable but somewhat indefinite distance into the interior, over which they assert that their authority extends, ought to be called Angola; lastly, the name is by most British geographers and travellers applied to that part of the preceding territory which lies between 8° 20′ and 9° 30′ S., and which nearly corresponds to the Portuguese sub-government of Angola. The natives, whose practice seems to harmonise with the third of these applications of the word, also call the country Dongo. With the exception of a flat, sandy, barren plain, that extends from the coast for a considerable distance inland, Angola, using the word in its most restricted sense, is mountainous and well-watered. Its chief rivers are the Coanza, which bounds it on the north, the Danda, which bounds it on the south, and the Benga. Most of the country is very fertile, producing palms, citrons, oranges, lemons, bananas, tamarinds, mangroves, and sugar canes in great abundance. Nor is the fauna less extensive; all the animals common in inter-tropical Africa are found in Angola, as well as some peculiar to the district; while the sheep, the cow, and the horse have been imported from Europe. Of its mineral productions, lead, sulphur, petroleum, and iron are plentiful; and gold, silver, and copper are said to exist in the interior. Gum, wax, and ivory are now the most important articles of trade; but formerly the principal traffic was in slaves. The heat is usually moderate, and the climate comparatively mild and salubrious. The religion of the natives of Angola is Fetichism; they believe implicitly in their priests, who pretend to bestow rain, favourable winds, and other blessings upon those who have propitiated them by liberal gifts. In criminal cases much use is made of what our ancestors called "the judgments of God." The accused is made to swallow poison, to take in his hand burning coals, or to undergo tests of a similar nature, and, unless he escapes unhurt from these trials, is pronounced guilty; of course the priests contrive that those whom they wish to absolve should suffer no harm. The native huts are formed merely of straw or dried leafy plants, intertwisted upon a framework of stakes; containing no aperture for the admission of light, they form not so much dwelling-houses, as dens for sleeping in, while the tenants spend the day and receive company in an open space in front that is covered with a slight roof. The population of Angola is estimated at about 250,000, of whom about 2000 are Europeans. Angola was discovered by the Portuguese under Diego Cam in 1484; and since that time, with the exception of a short period, from 1640 to 1648, during which the Dutch attempted to expel them, they have maintained their possession of the country undisturbed by other European powers. It cannot be said, however, that they have done much during this long rule either to develop the resources of the country or to improve the condition of its people; and, while they permitted an active slave trade to be carried on, their influence must have been much more injurious than beneficial. St Paul de Loanda, at which the governor resides, is the chief town. They possess a few forts in the interior, but over the greater part of the country their authority is hardly felt.

ANGORA, or ENGURI, the ancient *Ancyra*, a city of Turkey in Asia, capital of the vilayet of the same name, situated upon a steep hill, near a small stream, which flows into the Angara, a tributary of the Sakaria or Sangarius, about 220 miles E.S.E. of Constantinople. The modern town is not well built, its streets being narrow and many of its houses of mud; but there are a great many fine remains of Greek, Roman, and Byzantine architecture, the most remarkable of which is a temple of white marble, erected by the inhabitants in honour of Augustus. On the walls of this temple is the famous *Monumentum Ancyranum*, an inscription in Greek and Latin, detailing the principal events in the life of the emperor, a great part of which is still legible. Angora has long been celebrated for its goats, whose soft silky hair, about 8 inches long, forms the chief article of export from the town. The fineness of the hair may perhaps be ascribed to some peculiarity in the atmosphere, for it is remarkable that the cats, dogs, and other animals of the country are to a certain extent affected in the same way as the goats, and that they all lose much of their distinctive beauty when taken from their native districts. The other exports are goat and cat skins, gum, wax, honey, yellow berries, and madder root, while the import of British and other European goods is considerable, although the trade is almost entirely in the hands of Armenians. The population is variously estimated at from 20,000 to 60,000. Ancyra originally belonged to Phrygia, and afterwards became the chief town of the Tectosages, one of the three Gallic tribes that settled in Galatia, about 277 B.C. In 189 B.C., Galatia was subdued by Manlius, and in 25 B.C. it was formally made a Roman province, of which Ancyra was the capital. Ancyra was the seat of one of the earliest Christian churches, founded probably by the apostle Paul, and councils were held in the town in 314 and 358 A.D. In 1402 a great battle was fought in the vicinity of Ancyra, in which the Turkish sultan Bajazet was defeated and made prisoner by Tamerlane, the Tartar conqueror. In 1415 it was recovered by the Turks under Mahomet I., and since that period has belonged to the Ottoman empire.

ANGORNO, or NGORNU, a town of Bornu, in Central Africa, near the south-west shore of Lake Chad, from which it is separated by a level plain that is often under water. It is said to have a population of 30,000, which is much increased during the markets, when a large traffic is carried on in cotton, amber, metals, corals, and slaves.

ANGOSTURA, also called CIUDAD BOLIVAR, and SAN TOMAS DE LA NUEVA GUAYANA, a town of Venezuela, capital of the province of Guayana, situated on the right bank of the Orinoco, about 240 miles from its mouths, and only 191 feet above the level of the sea. It is the seat of a bishop, and contains a cathedral, a college, and an hospital, while a fort stands on the opposite side of the river, at this point comparatively narrow. Being the centre of a rich and extensive territory, Angostura would before now have probably become a large and flourishing city, had it not been retarded by the war of independence, and by the unsettled state of the country; for a long period it retrograded rather than progressed, and although now in a more prosperous condition, it has not yet reached the position to which it is entitled. The Orinoco is navigable for vessels of 300 tons, and a considerable trade is carried on in cocoa, sugar, cotton, jerked meat, and hides, as well as in the bark that takes its name from the city. In 1819 a congress met at Angostura, which resulted in the union of Venezuela and New Granada into one government under the name of the republic of Columbia; and in the same year the town began to be called Ciudad Bolivar, in honour of Simon Bolivar, who freed the country from the yoke of Spain. Population, about 8000.

ANGOULÊME, a city of France, capital of the department of Charente, and formerly of the province of Angou mois, situated on the left bank of the Charente, upon an elevated plateau, 221 feet above the river, at the foot of which, in the suburb of Houmeau, there is a station of the Paris and Bordeaux railway, 66 miles north-east of the latter town. The situation of Angoulême is very delightful, and the city itself is in general well built, although in the old quarter many of the streets are narrow and irregular. The chief public buildings are the cathedral of St Peter, rebuilt in 1120, but founded at a much earlier period; the remains of the old castle in the centre of the town, the birth-place of the celebrated Margaret of Valois, sister of Francis I.; the courthouse, and the town-hall. The town is the seat of a bishop, and has a court of primary jurisdiction, a lyceum, two normal, and several ordinary schools, an hospital, a theatre, and a public library. Angoulême is an important manufacturing city; its paper-mills produce large quantities of paper that is highly esteemed throughout France; and there are also distilleries, potteries, a cannon foundry, a powder mill, linen and serge factories, as well as a considerable trade in grain, fruit, and salt. Angoulême, the ancient *Iculisma*, was taken by Clovis from the Visigoths in 507; it was repeatedly plundered by the Normans in the 9th century, and was long subject to the counts of Angoulême, and also for a considerable period to the kings of England; but in 1303 Philip the Fair added it to the royal domain of France. In 1360 it was again surrendered to the English, who were, however, finally expelled in 1369. During the war of the Huguenots it was twice taken by the Protestants, in 1562 and 1568. Population (1872), 25,928.

ANGOULEME, Charles de Valois, Duke of, the natural son of Charles IX. of France and Marie Touchet, was born 28th April 1573, at the castle of Fayet in Dauphiné. His father, dying in the following year, commended him to the care and favour of his brother and successor, Henri III., who faithfully fulfilled the charge. His mother married Francois de Balzac, marquis d'Entragues, and one of her daughters, Henriette, marchioness of Verneuil, afterwards became the mistress of Henri IV. Charles of Valois was carefully educated, and was destined for the order of Malta. At the early age of sixteen he attained one of the highest dignities of the order, being made grand prior of France. Shortly after he came into possession of large estates left by Catherine de Medicis, from one of which he took his title of count of Auvergne. In 1591 he obtained a dispensation from the vows of the order of Malta, and married Charlotte, daughter of Henri, marshal d'Amville, afterwards duke of Montmorenci. In 1589 Henri III. was assassinated, but on his death-bed he commended Charles to the good-will of his successor Henri IV. By that monarch he was made colonel of horse, and in that capacity served in the campaigns during the early part of the reign. But the connection between the king and the marchioness of Verneuil appears to have been very displeasing to Auvergne, and in 1601 he engaged in the conspiracy formed by the dukes of Savoy, Biron, and Bouillon, one of the objects of which was to force Henri to repudiate his wife and marry the marchioness. The conspiracy was discovered; Biron and Auvergne were arrested, and Biron was executed. Auvergne after a few months' imprisonment was released, chiefly through the influence of his half-sister, his aunt, the duchess d'Angoulême, and his father-in-law. He then entered into fresh intrigues with the court of Spain, acting in concert with the marchioness of Verneuil and her father d'Entragues. In 1604 d'Entragues and he were arrested and condemned to death; at the same time the marchioness was condemned to perpetual imprisonment in a convent. She easily obtained pardon, and the sentence of death against the other two was commuted into perpetual imprisonment. Auvergne remained in the Bastile for eleven years from 1605 to 1616. In 1606 a decree of Parliament, obtained by Marguerite de Valois, deprived him of nearly all his possessions, including Auvergne, though he still retained the title. In 1616 he was released, was restored to his rank of colonel-general of horse, and despatched against one of the disaffected nobles, the duke of Longueville, who had taken Peronne. Next year he commanded the forces collected in the Isle de France, and obtained some successes. In 1619 he received by bequest, ratified in 1620 by royal grant, the duchy of Angoulême. Soon after he was engaged on an important embassy to Germany, the result of which was the treaty of Ulm, signed July 1620. In 1627 he commanded the large forces assembled at the siege of La Rochelle; and some years after, in 1635, during the Thirty Years' War, he was general of the French army in Lorraine. In 1636 he was made lieutenant-general of the army. He appears to have retired from public life shortly after the death of Richelieu in 1643. His first wife died in 1636, and in 1644 he married Francoise de Nargonne, daughter of Charles, baron of Mareuil. She had no children, and survived her husband many years. Angoulême himself died in 1650, in his seventy-sixth year. By his first wife he had three children: Henri, who became insane; Louis Emmanuel, who succeeded his father as duc d'Angoulême; and Francois, who died 1622.

The duke was the author of the following works:—(1.) *Mémoires, from the Assassination of Henri III. to the Battle of Arques*, published at Paris by Boneau, and reprinted by Buchon in his *Choix de Chroniques*, 1836, and by Petitot in his *Mémoires*, 1st series, vol. xliv.; (2.) *Les Harangues, prononcés en Assemblee de MM. les Princes Protestants d'Allemagne*, par Monseigneur le duc d'Angoulême, 1620; (3.) A translation of a Spanish work by Diego de Torres. To him has also been ascribed the work, *La générale et fidèle Relation de tout ce qui s'est passé en l'Isle de Ré, envoyée par le Roi a la Royne sa mère*, Paris, 1627.

ANGOUMOIS, an old province of France, nearly corresponding to the department of Charente. Its capital was Angoulême.

ANGRA, a city on the south coast of Terceira, one of the Azores, the capital of the island and of one of the three civil districts into which the Azores are divided, as well as the residence of the military governor of the whole group, and of the Roman Catholic bishops. It is a well-built, strongly fortified town, containing an arsenal for the Portuguese royal navy, a cathedral, and several churches, monasteries, and nunneries. The harbour is sheltered on the west and south-west by the promontory of Mount Brazil, and if this natural protection were supplemented by a breakwater on the south-east, the town would possess a secure and commodious anchorage; as it is, vessels during certain seasons are safer in the open sea. The chief exports are wine and grain; but foreign trade is not largo. Population, 11,281.

ANGRI, a town of Italy, in the province of Salerno, situated $11\frac{1}{2}$ miles N.W. of the town of Salerno, in a country which produces large quantities of grapes, cotton, and tobacco. Narses defeated Teias, the last king of the Goths, not far from Angri in 553 A.D. Population, 10,332.

ANGUIER, Francois (born 1604, died 1669), and Michael (born 1612, died 1686), two brothers, natives of Normandy, were distinguished sculptors in the time of Louis XIV. The chief works of Francis are the monument to Cardinal de Bérulle, in the chapel of the oratory at Paris, and the mausoleum of the last duc de Montmorency at Moulins. Michael executed the sculptures of the triumphal arch at the Porte St Denis. A marble group of the *Nativity* in the church of Val de Grâce, was reckoned his masterpiece.

ANGUILLA, or Snake Island, a small British West Indian island, one of the Lesser Antilles, situated 8 miles north of the island of St Martin, in lat. 18° 12′ N., and long. 63° 8′ W. Its chief products are salt, which is manufactured from a lake in the interior, sugar, cotton, maize, and tobacco, but the soil is comparatively barren, and there is a great deficiency of water in the island. Population, 3000.

ANGUSSOLA, or ANGOSCIOLA, SOPHONISBA, one of the best portrait painters of the latter half of the 16th century, was born at Cremona in 1533, and died at Genoa in 1620. In 1560, at the invitation of Philip II., she visited the court of Madrid, where her portraits elicited great commendation. Vandyck is said to have declared that he had derived more knowledge of the true principles of his art from her conversation than from any other source. She painted several fine portraits of herself, one of which is now at Althorp. A few specimens of her painting are to be seen at Florence and Madrid. She had three sisters, who were also celebrated artists.

ANHALT, a duchy of Germany, lying between lat. 51° 33′ and 52° 7′ N., and long. 11° and 12° 36′ E., and comprising an area of about 896 square miles. Except for a short distance on the west, and for a longer distance on the north-east, where it is bounded respectively by Brunswick and the Prussian province of Brandenburg, Anhalt is entirely surrounded by Prussian Saxony, which also intersects it, breaking it up into two large and several small portions. The Hartz mountains extend into the western of the large divisions, but the rest of the country is very flat, and even in the mountainous part no elevations rise to any great height. Most of the plain, which is watered by the Elbe and its tributaries, the Mulde and the Saale, is very fertile, producing large quantities of grain, tobacco, flax, hops, and fruits, especially grapes; cattle and sheep are reared in considerable numbers on the rich pasture lands; game and fish are abundant; while the mines in the Hartz mountains yield iron, lead, silver, and other minerals. The chief manufactures of Anhalt are linen, cotton, and woollen goods, metallic and earthen wares, beer, brandy, and sugar; but the principal export trade is in the raw products. Internally, Anhalt is governed by a constitutional and hereditary monarchy, the legislative body being a diet of 36 members, of whom 10 represent the nobility; 14, the principal towns; 10, the rural districts; and 2 are nominated by the duke, who has the entire executive power in his own hands; while, as a member of the German empire, the duchy has one vote in the Bundesrath, or Federal Council, and two in the Reichstag. Its income and expenditure for the year 1872 exactly balanced, being each 2,231,000 thalers, or £334,650; the public debt at the end of 1871 was 4,073,026 thalers, or £610,954. Anhalt contained 203,354 inhabitants in 1871, most of whom are Protestants. Its capital is Dessau, and the other chief towns are Bernburg, Köthen, and Zerbst. Railways connect these towns with one another, and also with Berlin and the principal cities of Germany. Bernard, son of Albert the Bear, margrave of Brandenburg, was the first upon whom the title of count of Anhalt was conferred. He died in 1212, and was succeeded in the principality of Anhalt by his son Henry I.; while Albert, a younger son, received his large possessions in Saxony. On the death of Henry in 1252, Anhalt was divided among his family into three parts,—Ascania, Bernburg, and Zerbst,—which were afterwards united under Joachim Ernest, who reigned from about 1570 to 1586. In 1603, however, the territory was again broken up, on this occasion into four parts, Dessau, Bernburg, Köthen, and Zerbst, four of Joachim Ernest's sons inheriting one of these divisions each, while the fifth, Augustus, who was the third in point of age, received a considerable sum of money, and the promise that, in the event of any one of the other lines becoming extinct, he or his descendants should succeed to the principality; his brother Christian, of Anhalt Bernburg, also gave him the small property of Plötzkau, from which he took his title. This promise was fulfilled in 1665, when William Louis of Anhalt Kothen died without direct heirs, and was succeeded by Lebrecht of Anhalt Plotzkau, who thereafter laid aside his own title. The Zerbst line becoming extinct in 1793, the principality, in accordance with a compact made in 1665, was divided among the three remaining families; next, by the death of Henry duke of Anhalt Kothen in 1847, that duchy was a second time left without direct heirs, but was ultimately incorporated with Dessau; and lastly, the Anhalt Bernburg family died out in 1863, leaving the whole of Anhalt under a single ruler. The present duke,—the title of duke was conferred upon the counts of Anhalt in 1807,—Frederick, succeeded his father Leopold in 1871, being at that time about forty years old. Several of the rulers of Anhalt have borne a conspicuous part in the affairs of Europe, and not a few of them have been noted for their zeal in the cause of Protestantism. Wolfgang, a prince of the earlier Zerbst line, was present at the diet of Augsburg in 1530, and was one of those who presented the confession to the emperor. Leopold I., of Anhalt Dessau, was one of the most distinguished soldiers of his time.

ANICHINI, LUIGI, an engraver of seals and medals, a native of Ferrara, lived at Venice about 1550. Michel Angelo pronounced his "Interview of Alexander the Great with the high-priest at Jerusalem," "the perfection of the art." His medals of Henry II. of France and Pope Paul III. are greatly valued.

ANIELLO, TOMMASO. See MASANIELLO.

ANILINE, or PHENYLAMINE (C_6H_7N), is one of the very numerous products of the distillation of coal tar. The substance has been known to chemists since the year 1826, when M. Unverdorben, by the destructive distillation of indigo, produced a liquid of an oily consistence, which he termed *crystalline*. In the year 1835, Runge, a German chemist, isolated from the oil of coal tar a substance which, having the property of producing a beautiful blue colour on treatment with chloride of lime, he named *kyanol*. In 1840, another investigator showed that by treating indigo with caustic potash it yields an oil, and he gave to his product the name *Aniline*, from the specific name of one of the indigo yielding plants, *Indigofera anil*. About the same time it was discovered that on treating nitrobenzol with a reducing agent, an organic base is formed, to which the observer of this reaction gave the name *benzidam*. Professor Hofmann, while a student in the laboratory of Baron Liebig, investigated these variously prepared substances, and found them to be identical in composition and action, and thenceforth they took their place as one body, under the name *Aniline* or *Phenylamine*. Pure aniline is a basic substance of an oily consistence, colourless, boiling at a temperature of 182° C. Dropped on paper aniline produces a greasy stain, which, owing to its volatilising at an ordinary atmospheric temperature, quickly disappears. On exposure to air it absorbs oxygen rapidly, and becomes of a deep brown colour; and it ignites readily, burning with a large smoky flame. It is possessed of a somewhat pleasant vinous odour, and a burning aromatic taste. It is a highly acrid poison, and Dr Letheby has pointed out that the poisonous action of nitrobenzol is due to a change of that substance into aniline taking place within the stomach.

The readiness with which aniline, in certain of its reactions, produces very brilliant colours, was of course known to chemists from the time Runge produced it from coal tar and gave it the name kyanol. Up to year 1858 it, however, possessed nothing beyond a scientific interest. On the 26th of August 1858, Mr W. H. Perkin obtained a patent for the production of a dye-stuff derived from aniline, which soon became well known as mauve, or Perkin's purple, as well as by various other names. The discovery of Mr Perkin formed the turning-point in the history of aniline, and was indeed the beginning of a great revolution in the arts and manufactures connected with the dyeing of textile fabrics. The manufacture of aniline dyes was really first begun in France, the French manufacturers acting on the information supplied by Mr Perkin's patent specification. It immediately spread to all industrial centres, and became one of the most eagerly investigated of all commercial undertakings. A rapid succession of patents were applied for and obtained; new processes and combinations were continually being projected, and a great variety of colours were tried with more or less success as commercial substances. The activity of scientific research kept pace with the energy of manufacturing enterprise, resulting in a rapid improvement of processes, decrease in the cost of the manufacture, and a great increase in the beauty and tinctorial effect of the dyes produced. At the present time every colour, and all tints and shades of colours, are produced from aniline; and, while the processes employed and the combinations formed are very numerous, the names under which the dye-stuffs are sold must be said to be endless.

Of the processes by which aniline may be prepared, that only is available in manufacturing which was devised by Zinin, when he prepared it, under the name of benzidam, from nitrobenzol. Aniline is only found in very small quantities as a direct product of the distillation of coal tar, but a large proportion of light hydrocarbons are among the products when the temperature ranges between 80° C. and 130° C. The chief of these is benzol, with smaller quantities of toluol and other closely allied substances. These hydrocarbons, when acted upon by strong nitric acid, give up an atom of hydrogen, the place of which is taken by one of nitroxyl (NO_2), and benzol is thus transformed into nitrobenzol: *i.e.*, benzol (C_6H_6) + nitric acid (HNO_3) = nitrobenzol ($C_6H_5NO_2$) + water (H_2O). Nitrobenzol is a yellow oily liquid, with the exact flavour of bitter almonds, for which it has long been used as a substitute in fancy soap-making, under the name of essence of mirbane. Its transformation into aniline is now practically effected by submitting it to the reducing influence of nascent hydrogen, by the action of iron and acetic acid. To a mixture of nitrobenzol and strong acetic acid a certain proportion of iron filings is gradually added. Very energetic chemical action is set up with great disengagement of heat. When the reaction is complete the aniline is distilled over by superheated steam. The aniline of commerce thus prepared is not a chemically pure product, but a mixture of aniline and toluidine, just as the commercial benzol operated on is a mixture of benzol with toluol. In the manufacture of dyes it is found essential that certain proportions of both aniline and toluidine should be present in the aniline oil operated on.

The method by which Mr Perkin obtains from aniline the violet colour known as mauve, is by mixing a solution of sulphate of aniline and of potassic dichromate in equivalent proportions, and leaving them for several hours till the resulting reaction is complete. A black precipitate is formed, which is washed free from the potassic sulphate it contains, and then treated with naphtha to dissolve out the resinous matter contained in the mass. The residue consists of the mauve dye, and may be dissolved in alcohol. It has been found to be the sulphate of a base, to which the name mauveine has been given.

The greater proportion of aniline dyes manufactured are now produced directly or indirectly from another basic body, termed rosaniline. About the time of the French-Austrian war in 1859, a second coal-tar dye was introduced into commerce, which became popularly known as aniline red or Magenta, from the battle fought at the period of its introduction. Dr Hofmann's investigations into the nature and composition of this dye have done more to place the entire industry on a satisfactory basis than any other undertaking. He found that it consisted of a salt of a basic substance, to which he gave the name rosaniline ($C_{20}H_{19}N_3H_2O$). For the preparation of rosaniline, Hofmann found that a certain proportion of toluidine must be present in the commercial aniline employed. Rosaniline is now entirely manufactured by treating aniline of a known composition with a strong solution of arsenic acid in an iron retort, heated to a temperature of not more than 180° C. The reaction occupies about eight hours; and at the conclusion of the operation a crude mass, consisting of rosaniline arsenite and arseniate, is found, which is next dissolved in water acidulated with hydrochloric acid. Common salt is added to this solution, when a double decomposition takes place. Rosaniline hydrochlorate is formed on the one hand, and sodium arseniate and arsenite on the other. For the preparation of the salts of rosaniline, the base is treated directly with acids.

Rosaniline blues are prepared by acting upon commercial aniline with a salt of rosaniline, such as the acetate, under the influence of a heat of about 190° C., kept up for two hours. The reaction which takes place is the substitution of three atoms of phenyl for three of hydrogen, and hence these blues are chemically salts of triphenylrosaniline. Violet colours, such as Hofmann's violet, are prepared by an analogous process to that employed for the blues, by treating rosaniline with the iodides of methyl or ethyl, atoms of these radicals taking the place of hydrogen, and forming ethylic or methylic rosaniline. Aniline green is formed by the action of aldehyd on a solution of aniline red in sulphuric acid, and subsequent boiling in a solution of hyposulphite of soda. Aniline yellow, or yellow fuchsine, is formed from a base named chrysaniline, a minor product of the formation of rosaniline; but most of what is termed aniline yellow is prepared from picric acid, a different product of the distillation of coal tar. Various shades of brown and maroon, as well as black colours, are regular commercial products; but they are neither so well understood, nor of such consequence as the reds, blues, and greens.

Aniline colours are employed in the industrial arts for numerous other purposes besides their great use as dyeing materials. Violet ink and other fancy coloured inks are prepared from them. They are used by paper manufacturers for tinting pulps, and for the superficial staining of finished paper. They are likewise used by paper stainers in the printing of wall papers, in the preparation of lithographic inks, and to some extent for water colours. They are largely employed as colouring materials in perfumery, fancy soaps, and cosmetics, besides having many other minor applications.

Concerning these dyes, Dr Hofmann, to whom the industry is so much indebted, wrote, in 1862, while it was yet in its infancy, "Instead of disbursing her annual millions for these substances, England will, beyond question, at no distant day become herself the greatest colour-producing country in the world; nay, by the very strangest of revolutions, she may erelong send her coal-derived blues to indigo-growing India, her distilled crimson to cochineal-producing Mexico, and her fossil substitutes for quercitron and safflower to China, Japan, and the other countries whence these articles are now derived." It is scarcely needful to say that these bold anticipations have already been fully realised.

ANIMAL KINGDOM

ANIMALS, CLASSIFICATION OF. The object of classification is to bring together those things which are like, and to separate those which are unlike. Each science has its own classification of the objects with which it deals, the kinds of likeness and unlikeness according to which these objects are grouped varying in relation to the special qualities or properties of matter with which the science is concerned. Thus, the physicist classifies bodies according to their mechanical, electrical, thermic, or other physical properties; the chemist, regards their composition; while the zoologist and the botanist group them according to their likenesses and unlikenesses of structure, function, and distribution.

As soon as the labours of anatomists had extended over a sufficiently great variety of animals, it was found that they could be grouped into separate assemblages, the members of each of which, while varying more or less in minor respects, had certain structural features in common, and these common morphological characters became the definition of the group thus formed. The smallest group thus constituted is a MORPHOLOGICAL SPECIES. A certain number of species having characters in common, by which they resemble one another and differ from all other species, constitutes a GENUS; a group of genera, similarly associated, constitutes a FAMILY; a group of families, an ORDER; a group of orders, a CLASS; a group of classes, a SUB-KINGDOM; while the latter, agreeing with one another only in the characters in which all animals agree, and in which they differ from all plants, make up the ANIMAL KINGDOM.

The formation of a morphological classification is therefore a logical process, the purpose of which is to throw the facts of structure into the smallest possible number of general propositions, which propositions constitute the definitions of the respective groups. A perfect classification will fulfil this end, and, in order to form it, two conditions are necessary: Firstly, we must have a full knowledge of the adult structure of every animal, recent and extinct; secondly, we must know all the modifications of structure through which it has passed, in order to attain the adult condition, or in other words, the mode of development of the animal. For it is the sum of all the structural conditions of an animal which constitutes the totality of its structure; and if two animals, similar in their adult state, were unlike in their development, it is clear that the latter circumstance would have to be taken into account in determining their position in a classification.

Linnæus, living at a time when neither comparative anatomy nor embryology can be said to have existed, based his classification of animals upon such broad resemblances of adult structure and habit as his remarkable sagacity and wide knowledge enabled him to detect. Cuvier and his school devoted themselves to the working out of adult structure, and the *Leçons d'Anatomie Comparée* and the *Règne Animal* are wonderful embodiments of the results of such investigations. But the Cuvierian system ignores development; and it was reserved for Von Baer to show the importance of developmental studies, and to inaugurate the marvellous series of researches which, in the course of the last fifty years, have made us acquainted with the manner of development of every important group of animals. The splendid researches of Cuvier gave birth to scientific palæontology, and demonstrated that, in some cases, at any rate, extinct forms of life present characters intermediate between those of groups which are at present widely different. The investigations of Agassiz upon fossil fishes tended in the same direction, and further showed that, in some cases, the older forms preserve, as permanent features, structural characters which are embryonic and transitory in their living congeners. Moreover, Darwin, Owen, and Wallace proved that, in any great area of geographical distribution, the later tertiary extinct forms are clearly related to those which now exist in the area. As Taxonomic investigations increased in accuracy and in extent, the careful examination of large suites of specimens revealed an unexpected amount of variability in species; and Darwin's investigation of the phenomena presented by animals under domestication proved that forms, morphologically as distinct as admitted natural genera, could be produced by selective breeding from a common stock.

Upon the foundation thus furnished, the doctrine of Evolution, first scientifically formulated by Lamarck, has been solidly built up by Darwin, and is now, with various modifications and qualifications, widely accepted. But the acceptance of this doctrine introduced a new element into Taxonomy. If all existing animals are the last terms of a long series of developmental stages, represented by the animals of earlier ages of the earth's history, the starting point of which has been a primordial form of the extremest simplicity consistent with animal life, then every animal has an "ancestral" as well as what may be termed a "personal" embryology; and the same considerations which oblige the Taxonomist to take account of the latter phenomena, compel his attention to the former stages of development. Two animals belong to the same group, when they are similar in structure, personal development, and ancestral development, and not otherwise. Hence it follows that a perfect and final zoological classification cannot be made until we know all that is important concerning—1, the adult structure; 2, the personal development; and 3, the ancestral development of animals. It is hardly necessary to observe that our present knowledge, as regards even the first and second heads, is very imperfect; while, as respects the third, it is utterly fragmentary.

The only genus of animals of which we possess a satisfactory, though still not quite complete, ancestral history, is the genus *Equus*, the development of which in the course of the Tertiary epoch from an Anchitherioid ancestor, through the form of *Hipparion*, appears to admit of no doubt. And all the facts of geology and palæontology not only tend to show that the knowledge of ancestral development is likely long to remain fragmentary, but lead us to doubt, whether even such fragments as may be vouchsafed to us by the extension of geological inquiry will ever be sufficiently old, in relation to the whole duration of life on the earth, to give us positive evidence of the nature of the earliest forms of animals.

While holding the doctrine of evolution to its fullest extent, and having no doubt that Taxonomy ought to be the expression of ancestral development, or *phylogeny*, as well as of embryogeny and adult structure, and while conceiving that the attempts at founding a scientific phylogeny, which have been made by Haeckel and others, are of much interest and importance as guides to and suggestors of investigation, the present writer looks upon all such attempts as provisional hypotheses; and he conceives that, at any rate for the present, it is a mistake to introduce considerations of this purely hypothetical kind into classification, which should be based on verifiable data.

In the case of an existing animal, it is possible to determine its adult structure and its development, and therefore to assign its place relatively to other animals, the structure and development of which are also known; and, in the case of an extinct animal, it is possible to ascertain certain facts of its structure, and sometimes certain facts of its development, which will justify a more or less positive assignment of its place relatively to existing animals. So far, Taxonomy is objective, capable of proof and disproof, and it should leave speculation aside, until speculation has converted itself into demonstration.

In the present rapidly shifting condition of our knowledge of the facts of animal structure and development, however, it is no easy matter to group these facts into general propositions which shall express neither more nor less than is contained in the facts; and no one can be more conscious of the manifold imperfections of the following attempt at such a classification than the author of it.

In certain of the lower animals, the substance of the body is not differentiated into histogenetic elements; that is, into cells[1] which, by their metamorphoses, give rise to tissues. In all other animals, on the other hand, the protoplasmic mass, which constitutes the primitive body, is converted into a multitude of cells, which become metamorphosed into the tissues of the body.

For the first of these divisions the old name of PROTOZOA may be retained; for the second, the title of METAZOA, recently proposed by Haeckel, may be conveniently employed.

I. THE PROTOZOA.

Haeckel has shown that, among the *Protozoa*, there are some which are simpler than the rest, inasmuch as they are devoid of both nuclei and contractile vesicles. To these he applies the name of—

1. *Monera.*—Among the members of this group, which are at present known, three series are distinguishable, in all of which multiplication is effected by division, preceded, or not preceded, by the assumption of an encysted condition. In one state, each of these *Monera* is a *myxopod*,[2] that is, is provided with longer or shorter pseudopodia as locomotive organs, and, in *Protamœba* and *Protogenes*, the result of the process of division is also two or more myxopods. But, in *Protomonas*, the myxopod, after becoming encysted, gives rise by division to bodies provided with long flagelliform cilia, by which they are propelled, and which may be termed *mastigopods;* and in *Myxastrum*, the encysted body divides into a multitude of oval particles, each enclosed in its own coat. These are set free, and each gives rise to a new myxopod of the same character as the parent.

In *Protomyxa*, the myxopods coalesce into a reticulated plasmodium; and *Vampyrella* is parasitic, devouring stalked diatoms, and encysting itself upon the ends of their stalks, the encysted form dividing into new *Vampyrellæ*. Most of these interesting *Monera* have been made known by Haeckel, so that in all probability, many others remain to be discovered. It is probable that the *Foraminifera*, notwithstanding the complexity of the skeletons, belong to this group, but too little is known of the structure of their soft parts to enable any certain conclusion to be drawn respecting them, and the analogy of *Gromia* leads to the suspicion that they may belong to the next division.

2. *Endoplastica.*—In these *Protozoa* a portion of the interior protoplasmic body is separated from the rest as a distinct, more or less rounded, body, which may be termed the *endoplast*, as a term suggestive of its similarity to the nucleus of a histogenetic cell, without implying its identity therewith. Of such endoplasts there may be one or many, but the protoplasm in which they lie does not give rise to cells, which become metamorphosed into elements of the tissues. Very often they possess one or more vacuoles, which rhythmically dilate and contract, in accordance with the changes in the protoplasm in which they lie, and which are termed *contractile vesicles.*

In this division of the *Protozoa*, three groups—the *Amœbidæ*, the *Flagellata* (or flagellate *Infusoria*), and the *Gregarinidæ*—closely repeat the forms and mode of reproduction of the *Protamœbidæ*, *Protomonadidæ*, and *Myxastridæ* among the *Monera.* Among the rest, the *Acinetidæ* are distinguished by their pseudopodia being converted into suckers, through which they draw the juices of their prey. In all these, and in the preceding forms, there is a more or less marked distinction of the protoplasm constituting the body into a firmer and denser outer layer, the *ectosarc*, and a more fluid inner substance, the *endosarc;* and, in some of the *Gregarinidæ*, the ectosarc becomes differentiated into muscular fibres. In the *Flagellata* there is a permanent oral aperture; and in one member of this group, *Noctiluca*, additional complications of structure, in the form of a ridge-like tooth and a tentacle, occur. In the *Radiolaria*, the body is still more clearly differentiated into an inner substance, surrounded by a capsule, and containing nuclei and even cells, and a vacuolated ectosarc, whence the radiating pseudopodia proceed. Coloured corpuscles, usually yellow, appear in the ectosarc, and have been shown by Haeckel to contain starch and to multiply independently. In the *Ciliata* (ciliated *Infusoria*), with which the *Catallacta* of Haeckel may be included, the differentiation of the protoplasm of the body, without any development of histogenetic cells, goes still further. A permanent mouth and anus may appear, connected by a permanently softer and more fluid region of the protoplasm (as is plainly to be seen, for example, in *Nyctotherus*) foreshadowing an intestinal cavity. The ectosarc may be differentiated into a specially modified cortical layer, and well-marked muscular fibres may be developed. Moreover, the endoplast, or "nucleus," becomes an organ of reproduction, the germs of the young being given off by division from it. Very generally, a small body—the so-called "nucleolus," but which has, admittedly, nothing to do with the structure so named in a true cell, and may be termed the "endoplastula"—is to be found close to the nucleus, and there is some ground for supposing it to be a testis. The *Infusoria* frequently multiply by fission, which may, or may not, be preceded by encystment; and in many of them, as in the *Gregarinidæ*, *Acinetidæ*, and some *Flagellata*, conjugation has been observed. It is yet disputed how far the conjugation is a necessary antecedent of the process of endogenous germ formation.

Ehrenberg concluded, from those remarkable researches which first gave a clear insight into the structure of the ciliated *Infusoria*, that they were animals of complex structure, possessing, on a minute scale, all the organs characteristic of the higher forms of animal life. In opposition to this view, Dujardin started the conception that they are little more than masses of sarcode (=protoplasm); and Von Siebold, modifying this view in accordance with the cell theory, regards them as the equivalents of single cells of the tissues of the higher animals. The result of the long controversy which has been carried on on this subject seems to be, on the one hand, that Ehrenberg was quite right in vindicating for the *Infusoria* a far greater complexity of structure than they had been supposed to possess. It is certain that an Infusorium may possess a distinct integumentary layer, muscles, a permanent œsophagus, a permanent anal area, and, in some cases, a persistent tract

[1] The term "cell" is used here in its broadest sense, as equivalent to a nucleated mass of protoplasm.

[2] The term "Rhizopod" is already employed in a limited and special sense.

of the body substance, more permeable to alimentary matters than the rest, which might be fairly termed a permanent alimentary tract. Moreover, there is much reason for regarding the endoplast and endoplastula as generative organs, while there is, sometimes, a rather complex persistent system of water vessels. But, on the other hand, this complexity of organisation is different from that observed in the higher animals, inasmuch as the various structures enumerated do not result from the metamorphosis of histogenetic cells, but arise by immediate differentiation of the finely granular protoplasm of which the body is composed. And, so far, Von Siebold appears to have been fully justified in regarding a ciliated Infusorium as the homologue of a single cell. This is a view which will present no difficulty to those who are familiar with the morphology of the lower plants. The complicated mycelium of *Mucor Mucedo*, for example, is, while young, nothing but a single cell; and, in *Caulerpa*, a single undivided cell grows, without division, into an organism which simulates one of the higher Algæ in the diversity of its parts.

II. The Metazoa.

The germ becomes differentiated into histogenetic cells, and these cells become arranged into two sets, the one constituting the outer wall of the body, or *ectoderm*, while the other, or *endoderm*, lies internal to the foregoing, and constitutes the lining of the alimentary cavity, when, as is usually the case, a distinct alimentary cavity exists. In the embryo, the representatives of these two layers are the *epiblast* and *hypoblast*.

All the *Metazoa*, in fact, commence their existence in the form of an ovum, which is essentially a nucleated cell, supplemented by more or less nutritive material, or *food yelk*. The ovum, after impregnation, divides into cleavage masses, or *blastomeres*, giving rise to a *Morula*, in the midst of which arises a cavity, the *blastocœle* (*cleavage cavity*, "*Furchungshöhle*" of the Germans), which may be larger or smaller, filled only with fluid, or occupied by food yelk. When it is largest, the blastomeres, disposed in a single layer, form a spheroidal vesicle, enclosing a correspondingly shaped blastocœle. When it is reduced to a minimum, the *Morula* is an almost solid aggregation of blastomeres, which may be nearly equal in size, or some may be much larger than others, in consequence of having undergone less rapid division. The next stage in the development of the embryo of a *Metazoon* consists (in all cases except a few parasitic auenterous forms) in the conversion of the *Morula* into a body having a digestive cavity, or a *Gastrula*. The animals in which the embryo takes on the form of a *Gastrula*, may be termed, as Haeckel has proposed, *Gastrææ*.

The conversion of the *Morula* into the *Gastrula* may take place in several ways.

In the simplest, the *Morula* being composed of equal or nearly equal blastomeres, more or less completely converted into cells, these differentiate themselves into an outer layer, the epiblast, investing the remaining cells, which constitute the hypoblast. The central cells of the hypoblast next diverge and give rise to a space filled with fluid, the alimentary cavity, which opens at one end, and thus gives rise to the *Gastrula*. This is the process generally observed in *Porifera*, *Cœlenterata*, *Turbellaria*, *Trematoda*, and *Nematoidea*.

In a second class of cases, the *Morula* becomes converted into blastomeres of unequal sizes, a small and a large set. The smaller rapidly become converted into cells, and invest the larger and any remains of the food yelk, as a blastoderm, which at first represents only the epiblast of the former case. The hypoblast arises either from the epiblast thus formed, or from the included larger blastomeres. This is the process observed in certain *Turbellaria*, in the *Ctenophora*, in the *Oligochæta* and *Hirudinea*, in the *Arthropoda*, and in most *Vertebrata*.

In a third group of instances, the *Morula*, whether consisting of equal or unequal blastomeres, becomes spheroidal, and encloses a correspondingly shaped blastocœle. One part of the wall of this vesicular *Morula* then becomes invaginated, and gives rise to the alimentary cavity, with the hypoblast which limits it. This process has been observed in the *Chætognatha*, *Echinodermata*, *Gephyrea*, polychætous *Annelida*, *Enteropneusta*, *Brachiopoda*; in most *Mollusca*; in *Amphioxus*; and, slightly modified, in *Petromyzon* and in the *Amphibia*. These various modes in which the two primary layers of the germ may be developed shade off into one another, and do not affect the essence of the process, which is the segregation of one set of cells to form the external covering of the body, and of another set to constitute the lining of the alimentary canal.

In whatever manner the *Gastrula* is formed, and whatever be its shape when its alimentary cavity is complete, one of two things happens to it. It becomes provided with many ingestive apertures, distinct from that first formed; or with only one, which may or may not be distinct from the first aperture. The former division comprises only the Sponges (*Porifera* or *Spongida*) in which, as the remarkable researches of Haeckel have shown, the walls of the deeply cup-shaped *Gastrula* become perforated by the numerous inhalent ostioles, while the primitive opening serves as the exhalent aperture. These may be termed the *Metazoa polystomata*.

The latter division includes all the remaining forms, which may be grouped together as *Metazoa monostomata*. Among these, two primary groups are distinguishable, of which the second exhibits an advance in organisation upon the first. In the first, the aperture of the *Gastrula* becomes the permanent mouth (*Archæostomata*). In the second, the permanent mouth is a secondary perforation of the body wall (*Deuterostomata*).

1. It is now well established that the aperture of the *Gastrula* becomes the oral aperture of the adult in the *Cœlenterata*, which group includes animals differing much in grade of organisation, from the simple *Hydra* to the complex *Ctenophore*, but all manifestly exhibiting variations of one fundamental type. Parallel with these may be ranged an assemblage composed of the *Turbellaria*, *Rotifera*, and *Trematoda*, which are associated together by the closest resemblances of structure, and which present an even greater range in grade of organisation than the *Cœlenterata*. The lower *Rhabdocœla* come very close to the *Infusoria* (as close as the multicellular to the unicellular Algæ), and are but little superior to *Hydra* in the degree of their organic differentiation; while, in the *Trematoda*, the land *Planariæ*, and the *Nemertidæ*, we have animals which attain a considerable complexity, and in the case of many *Trematoda* and of *Lineus* (*Pilidium*) undergo remarkable metamorphoses. As a cognate group, the *Nematoidea* may be enumerated, extremely simple in their lowest forms, considerably differentiated in the higher, and connected with the *Turbellaria* by such forms as *Polygordius*. The *Oligochæta* and the *Hirudinea* also belong to this division of *Scolecimorpha*, but they differ from the foregoing in the development of a segmented mesoblast.

In the *Cœlenterata*, *Nematoidea*, *Turbellaria*, *Trematoda*, and *Rotifera*, the mode of origin of the cells which lie between the epiblast and the hypoblast, constitute the mesoblast, and give rise to the connective tissue and muscles of the body wall and of that of the intestine is not precisely known. They may take their origin in the epiblast, or in the hypoblast, or in both. But in the *Oligochæta* and the *Hirudinea*, after the epiblast and hypoblast are differentiated the cells of the latter give rise by division to two bands of cells, which lie, one on each side of the long axis of the ventral face of the worm, and constitute the mesoblast. This becomes marked out by transverse constriction into segments, and, in each segment, gives rise to all the tissues which lie between the epiblast (epidermis) and hypoblast (epithelium of the alimentary canal). The mouth corresponds with the primitive involution of the *Morula;* the anal aperture is a new formation. In the *Nematoidea* and in the lower Rhabdocœle *Turbellaria*, the intestinal canal is a simple tube or sac. But in some *Turbellaria* and *Trematoda*, the alimentary canal gives off diverticula, which ramify through the mesoblast and even unite together. The like takes place in a great many *Cœlenterata*, and the "gastrovascular apparatus," as it has been well termed, which is thus formed, is highly characteristic of them. The animals just referred to, therefore, have an "enterocœle" more or less distinct from the proper digestive cavity, but connected with it, and ramifying through the mesoblast.

2. In the remaining members of the animal kingdom, the embryo develops a secondary mouth as a perforation of the body wall, the primary aperture sometimes becoming the anus, and sometimes disappearing. Of these *Metazoa deuterostomata*, there are some which follow the mode of development of the *Oligochæta* and *Hirudinea* very closely, so far as the formation and segmentation of the mesoblast is concerned, though the question, whether this segmented mesoblast arises from the epiblast or the hypoblast, has not been exhaustively worked out. These are the *Annelida polychæta;* and there is the closest resemblance in development between them and the lower *Arthropoda* (*Crustacea*, *Arachnida*, lower *Insecta*), while, in the higher Arthropods, the process is complicated by the development of an amnion, and by some other special peculiarities which need not be considered in detail. In all these *Metazoa*, whatever cavities are developed in the mesoblast, whether a wide perivisceral cavity, or vascular canals, or both combined, they arise from the splitting or excavation of the mesoblast itself, and are not prolongations of the alimentary cavity. Hence they may be termed *Schizocœla.*

But, in certain other deuterostomatous *Metazoa*, the mesoblast becomes excavated, and a "perivisceral cavity" and vessels are formed in quite another fashion.

Thus in the *Chætognatha*, represented by the strange and apparently anomalous *Sagitta*, Kowalewsky's researches show, that the vitellus undergoes complete segmentation, and is converted into a vesicular *Morula*, on one side of which involution takes place, and gives rise to the primitive alimentary canal, of which the opening of involution becomes the permanent anus, the mouth being formed by perforation at the opposite end of the body. Before the mouth is formed, however, the primitive alimentary cavity throws out, on each side, a cæcal pouch, which extends as far forwards as its central continuation does, and grows backwards behind the anus. The two sacs, thus prolonged posteriorly, meet, but remain divided from one another by their applied walls in the median line. These lateral sacs now become shut off from the median portion of the primitive alimentary cavity (which opens at its anterior end, and becomes the permanent alimentary canal), and are converted into shut sacs, the cavity of each of which forms one-half of the perivisceral cavity. The inner wall of each sac, applied to the hypoblast, gives rise to the muscular wall of the intestine; and the outer wall, applied to the epiblast, becomes the muscular wall of the body, and from it the generative organs are evolved. The great ganglia and nerves are developed from the cells of the epiblast. Thus *Sagitta* is temporarily cœlenterate, but the two gastrovascular sacs, each enclosing an enterocœle, become shut off from the alimentary canal and metamorphosed into the walls of the perivisceral cavity. But it is not altogether clear whether the cells of the enterocœle give rise only to the lining of the perivisceral cavity, and whether the muscles and connective tissue are otherwise derived or not. Kowalewsky's evidence, however, is in favour of the origin of the muscles directly from the cells of the mesoblastic diverticula.

In the *Echinodermata*, the brilliant investigations of Johannes Müller, confirmed in their general features by all subsequent observers, proved, firstly, that the ciliated embryonic *Gastrula* (the primitive alimentary canal of which is formed by involution of a vesicular blastoderm), to which the egg of all ordinary Echinoderms gives rise, acquires a mouth, by the formation of an aperture in the body wall, distinct from the primitive aperture of the *Gastrula*, so that, in this respect, it differs from the embryo of all *Cœlenterata;* secondly, that the embryo thus provided with mouth, stomach, intestine, and anus acquires a complete bilateral symmetry; thirdly, that the cilia, with which it is primitively covered, are ultimately restricted to one or more series, some of which encircle the axis of the body, or a line drawn from the oral to the anal apertures; and fourthly, that, within this bilaterally symmetrical larva or *Echinopædium*, as it may be called, the more or less completely radiate Echinoderm is developed by a process of internal modification.

Müller believed that the first step in this process was the ingrowth of a diverticulum of the integument, as a hollow process, which became converted into the ambulacral vascular system of the Echinoderm. He did not attempt to explain the origin of the so-called blood-vascular system, or pseudhæmal vessels, nor of the perivisceral cavity. Müller's conclusions remained unchallenged until 1864, when Prof. Alexander Agassiz took up the question afresh, and, in a remarkable paper on the development of the genus *Asteracanthion*, detailed the observations which led him to believe that the ambulacral vessels do not arise by involution of the external integument, but that they commence as two primitively symmetrical diverticula of the stomach (the "würstformige Körper" of Müller), one of which becomes connected with the exterior by an opening (the dorsal pore observed by Müller, and considered by him to be the origin of the ambulacral vessels), and gives rise to the ambulacral vessels, the ambulacral region of the body of the Echinoderm being modelled upon it; while upon the other gastric sac, the antambulacral wall of the starfish body is similarly modelled. Both gastric sacs early become completely separated from the stomach of the *Echinopædium*, and open into one another, so as to form a single horseshoe-shaped sac, connected with the exterior by a tube which is converted into the madreporic canal. Agassiz does not explain the mode of formation of the perivisceral cavity of the starfish, and has nothing to say respecting the origin of the pseudhæmal vessels.

Recently, Metschnikoff has confirmed the observations of Agassiz, so far as the development of the ambulacral system from one of the diverticula of the alimentary canal of the starfish larva is concerned, and he has added the important discovery that the perivisceral cavity of the Echinoderm is the product of what remains of these diverticula. Moreover, his observations on other *Echinodermata* show that essentially the same process of development of the peritoneal cavity occurs in *Ophiuridæ*, *Echinidæ*, and *Holothuridæ.*

The precise mode of origin of the pseudhæmal system, or so-called blood-vessels, of the Echinoderms is not yet made out. But it is known that the cavity of these vessels contains corpuscles similar to those which are found in the perivisceral cavity and in the ambulacral vessels, and that all three communicate.

Both Agassiz and Metschnikoff justly insist upon the correspondence in development of the lateral gastric diverticula of the *Echinopædium* with the gastrovascular canal system of the *Ctenophora;* and, on the ground of this resemblance, the former refers the Echinoderms to the *Radiata*, retaining under that Cuvierian denomination the *Acalephæ* (*Cœlenterata*) and the *Echinodermata*. But this arrangement ignores the real value of his own discovery, which shows that the Echinoderms have made a great and remarkable step, in passing from their primarily cœlenterate stage of organisation to their adult condition. And it further ignores the unquestionable fact, admirably brought out by the same excellent observer's recent investigations into the development of *Balanoglossus*, that the *Echinopædium* is almost identical in structure with the young of animals, such as the *Gephyrea* and *Enteropneusta*, which are in no sense radiate, but are, eminently, bilaterally symmetrical. In fact, the larva of *Balanoglossus* (the sole representative of the *Enteropneusta*), was originally described by Müller, under the name of *Tornaria*, as an Echinoderm larva; and was subsequently more fully examined by Prof. Alex. Agassiz, who also regarded it as an unquestionable Echinoderm larva; and it is only recently that it has been proved, partly by Metschnikoff and partly by Agassiz himself, to be the larval form of *Balanoglossus*. In *Balanoglossus*, as in the Echinoderms, it appears that saccular outgrowths of the intestine give rise to the perivisceral cavity and its walls; and, if such be the case, the mesoblast will be chiefly, if not wholly, represented by diverticula of the alimentary canal. Thus in the *Chætognatha* and *Echinodermata*, and possibly in the *Enteropneusta*, the perivisceral cavity is a portion of the alimentary cavity shut off from the rest; and, in contradistinction to the *Schizocœla*, in which the perivisceral cavity is produced by a splitting of the mesoblast, they may be said to be *Enterocœla*.

If we endeavour to determine the place of the three remaining great groups of animals, the *Mollusca*, the *Tunicata*, and the *Vertebrata*, obstacles arise,—firstly, from a want of sufficiently exact knowledge respecting the *Mollusca;* and secondly, from the difficulty of interpreting certain well-ascertained facts in the *Vertebrata*.

That the *Mollusca*, including under that name the *Polyzoa* and *Brachiopoda*, as well as the higher Mollusks, are closely allied to the *Annelida*, is readily demonstrated. The known forms of Brachiopod, Lamellibranch, Pteropod, and Gasteropod larvæ all have their parallels among Annelidan larvæ. The *Polyzoa* are closely allied with the *Gephyrea* and *Rotifera;* and a Mollusk may be said to be a few-segmented annelid with a mantle. But whether the perivisceral cavity is developed in the annelidan or in the echinoderm fashion is not yet clear. In the *Polyzoa*, the evidence is at present insufficient to justify any conclusion. In the *Brachiopoda*, there is some ground for thinking that the perivisceral cavity is formed in the same way as in *Sagitta* and the *Echinodermata*; while, in the *Lamellibranchiata* and *Odontophora*, there is every reason to believe that the perivisceral cavity is formed by splitting of the mesoblast, or that they are schizocœlous.

In the lowest *Tunicata*, represented by *Appendicularia*, the recent investigations of Fol have shown, that, in the adult, the body proper is formed almost exclusively by an ectoderm and endoderm, which proceed directly from the epiblast and hypoblast of the embryo. It is only in the caudal appendage that a distinct mesoblast is represented by the notochord and the muscles. The blood channels correspond with the blastocœle, and the "house" in which these singular animals shelter themselves is a cuticular secretion, representing the cellulose coat of the higher ascidians. The *Appendicularia* have no *atrium*, or at most only rudiments of it, hence the branchial clefts open directly on the hæmal aspect of the body, which corresponds with the ventral face of a vertebrate animal. In all other *Tunicata*, an atrial cavity is formed by involution of the ectoderm, which thus gives rise to a cavity on each side of the branchial sac, into which the branchial clefts of the adult open; and a thick cellulose *cuticula*, into which cells from the ectoderm usually wander, invests the exterior of the body. The "atrial tunic," or invaginated layer of the ectoderm, is reflected, as a visceral layer, over more or less of the outer surface of the alimentary canal, and, as a parietal layer, over more or less of the inner surface of the body wall; and the space between the two (the blastocœle) becomes converted into the blood passages. Thus, such an ascidian resembles a vertebrated animal, not only in the manner in which its nervous centre is developed, but in the fact that it possesses an atrial cavity, which singularly resembles the pleuroperitoneal chamber of a vertebrate. For this cavity is bounded externally by the atrial tunic and the integument, which correspond with the somatopleural layer of the mesoblast and the epiblast of a vertebrate embryo; and it is bounded, internally, by the atrial tunic and the epithelium of the alimentary canal, which, to the same extent, correspond with the splanchnopleure and the hypoblast. The primitively double atrial aperture has its parallel in the peritoneal openings which persist in many *Vertebrata*.

Thus the ascidian has no "perivisceral cavity" formed by splitting of the mesoblast, nor has it any "perivisceral cavity" formed by diverticula from the alimentary canal. It is neither enterocœlous nor schizocœlous, but what, at first sight, resembles a perivisceral cavity is formed within the body by involution, and the ascidian may therefore be said to be *epicœlous*. If the alate prolongations of the body which lie at the sides of the branchial apertures, in *Balanoglossus*, were to enlarge and unite round the anus so as to leave but a relatively small opening between their edges, the cavity so formed would answer to the atrial chamber of an ascidian.

In the higher *Vertebrata*, the pleuroperitoneal[1] cavity appears to be formed by the splitting of the mesoblast into two layers, a splanchnopleure and a somatopleure, and, therefore, seems at first to correspond with the perivisceral cavity of the Annelids and Arthropods. But what is now known of the structure and development of the lowest and most embryonic of known *Vertebrata*, *Amphioxus*, throws very great doubt upon this interpretation of the facts. One of the most singular of the many peculiarities of *Amphioxus* is the fact that the branchial clefts open, not on the exterior of the body, as in all other *Vertebrata*, but into a chamber with a single external aperture, which, on the one hand, curiously resembles the atrium of an ascidian; while, on the other, it is undoubtedly homologous with the pleuroperitoneal cavity of the higher *Vertebrata*. Now Kowalewsky's investigations have shown, that, at first, the branchial apertures of the embryo *Amphioxus* open upon the exterior of the body, but that, after a time, a process of the wall of the body, on the dorsal side of the branchial apertures, grows down over them, and, uniting with its fellow in the median ventral line of the body at all points, except at the abdominal pore, gives rise to the outer wall of the pleuroperitoneal cavity. Thus the lining of that cavity, like the atrial tunic of the ascidian, is a derivative of the epiblast; and *Amphioxus* is epicœlous. As it can hardly be doubted that the somatopleure of *Amphioxus* is the homologue of the somatopleure in the higher *Vertebrata*, it becomes

[1] It must be recollected that the pericardium is also originally a part of this cavity, and that in some fishes, *e.g.*, the Rays, it never becomes completely shut off from it.

highly probable that the apparent splitting of the mesoblast in the latter, after all, represents the mode of development of the pleuroperitoneal cavity which obtains in the former, and, thus; that the *Vertebrata* are not schizocœlous, but epicœlous. Whether this suggestion will turn out to be well based or not, must be decided by the embryological investigations specially directed to this point: but that there should be any essential difference between *Amphioxus* and other *Vertebrata*, in the manner in which the pleuroperitoneal cavity is formed, is highly improbable.

The distance between *Amphioxus* and other vertebrate animals, which has hitherto been generally supposed to exist, has been greatly diminished by recent investigations. So far from being devoid of a brain and of a skull, the regions of the cerebro-spinal axis and of the neural canal, which answer to those organs in the higher *Vertebrata*, are, in proportion, extremely long in *Amphioxus*, as they are in all vertebrate embryos. But, in *Amphioxus*, the head retains throughout life a segmentation comparable to that of the rest of the body, while, in the higher *Vertebrata*, almost all traces of these distinct segments are very early lost. Moreover, in *Amphioxus*, the renal apparatus, so far from being absent, is represented by a comparatively large structure, and nothing is wanted to equip it with all the organs found in a young Marsipobranch, but auditory sacs, which, however, it must be remembered, make their appearance late in the Lamprey. With all this, the gap between *Amphioxus* and the *Marsipobranchii* is undoubtedly more considerable than that between the *Marsipobranchii* and other fishes, and it may represent a primary division of the class *Pisces*,—which, from the segmentation of the skull, may be termed the *Entomocrania*,—as opposed to the rest, in which the primary segmentation of the skull is almost completely effaced, and which may therefore be designated *Holocrania*.

It has been stated above that the great majority of the *Metazoa* pass through the *Gastrula* condition, and belong to the division of the *Gastrææ*. In some members of this division, however, the alimentary canal may be rudimentary, as in sundry male *Rotifera* and in the *Gordiacei* among the *Nematoidea*, and yet these are so closely allied to other forms possessing fully developed digestive canals, that it is reasonable to regard their rudimentary alimentary apparatus as absorbed. In two groups, however, the *Cestoidea* and the *Acanthocephala*, there is no trace of an alimentary canal either in the embryo or in the adult.

From the point of view of phylogeny, this fact may be interpreted in two ways. Either the alimentary canal which once existed has aborted, and the *Cestoidea* and *Acanthocephala* are modified *Scolecimorpha*, or these parasites have not descended from *Gastrææ*, but have passed into their present condition directly from a *Morula*-like form of *Metazoon*. In the latter case they will form a division of *Agastrææ*, apart from the other *Metazoa*.

The subjoined synopsis indicates the general relations of the different groups of the Animal kingdom, in accordance with the views which have been put forward in the preceding pages.

Those who are familiar with the existing condition of our knowledge of animal morphology, will be aware that any such scheme must needs, at present, be tentative and subject to extensive revision, in correspondence with the advance of knowledge. Nor will they regard it as any objection to the scheme of classification proposed, that the divisions sketched out may be incapable of sharp definition—the constant tendency of modern investigations being to break through all boundaries of groups, and to fill up the gaps between them by the discovery of transitional forms. In the place of assemblages of distinctly definable groups, which it has hitherto been the object of the Taxonomist to define and co-ordinate in precise logical categories, we are gradually learning to substitute series, in which all the modifications by which a fundamental form passes from lower to higher degrees of organic complication, are summed up. (T. H. H.)

ANIMALIA.

I.—PROTOZOA.

i. MONERA.
Protamœbidæ. Protomonadidæ. Myxastridæ, &c.

ii. ENDOPLASTICA.
Amœbidæ. Flagellata. Gregarinidæ. Acinetida. Ciliata. Radiolaria.

II.—METAZOA.

A. Gastrææ.

i. POLYSTOMATA.
Porifera (or Spongida).

ii. MONOSTOMATA.

1. ARCHÆOSTOMATA.

a. Scolecimorpha.

Rotifera. Turbellaria. Trematoda. Nematoidea. Hirudinea. Oligochæta

β. Cœlenterata.

Hydrozoa. Actinozoa.

2. DEUTEROSTOMATA.

a. Schizocœla.

Annelida (Polychæta). *Gephyrea.* *Brachiopoda* (?) *Polyzoa* (?) *Arthropoda.* *Mollusca.*

b. Enterocœla.

Enteropneusta. *Chætognatha.* *Echinodermata.*

c. Epicœla.

Tunicata. *Vertebrata.*

B. Agastrææ (provisional).
Acanthocephala. Cestoidea.

ANIME, a resinous exudation from the *courbaril* tree, which grows in the West Indies and in South America. When imported in the natural state it is infested with vast numbers of insects, and hence the name. It is of a pale brown colour, transparent, brittle, and in consequence of its agreeable odour is much used for fumigation and in perfumery. Its specific gravity varies from 1·028 to 1·054. It melts readily over the fire, and softens even with the heat of the mouth, but is insoluble in water. It is dissolved by alcohol, but not completely, unless the spirit be boiling. It is allied to copal in its nature and appearance, and is much used by varnish-makers.

ANIMISM, a term formerly employed in Biology to denote the theory of which Stahl is the chief expositor; the theory of the soul (*anima*) as the vital principle, cause of the normal phenomena of life, or of the abnormal phenomena of disease. It is now current in the wider anthropological sense given to it by Dr E. B. Tylor (*Primitive Culture*, chapters xi.–xvii.), as including the *general doctrine of souls and other spiritual beings.* This application is not only appropriate, but is even rendered indispensable by the absence of any other suitable word; for *spiritualism*, though occasionally used in a general sense, has become associated with a particular modern development of animistic doctrine; *anthropomorphism*, if less objectionable, is also to some degree inadequate; while the term *theology* cannot be extended to include the lower forms of the doctrine of spiritual beings, and indeed many of its higher developments, except by an ill-considered departure from ordinary usage, which raises in many minds a prejudice against the most reliable results of anthropological inquiry.

An animistic philosophy, explaining the more strange or striking phenomena of nature by the hypothesis of spiritual agency, is universally prevalent among savage races; and unless the wide-spread animistic beliefs of savages are to be regarded as but degenerate or corrupted relics of those possessed by more cultured peoples,—a theory which can scarcely be held to account for the essential and native appropriateness of animism as it flourishes among races of low culture, and its less appropriate and apparently derivative character as it survives in higher civilisations,—there seems tenable ground for the inference, that an animistic philosophy must have been that which was earliest developed among the prehistoric societies of mankind. In accordance with this view, animism may be described as the distinctive philosophy of primitive culture. It is manifestly the outcome and development of that earliest analogical reasoning, which concludes external objects to be animated with a life essentially similar to our own; it is the expression and application of our first general theory of natural causes,—a theory rude and inadequate, yet marvellously self-consistent and serviceable: and its history appears primarily to be that of a dominant and pervading philosophy, applied to explain all the phenomena of nature and life, save only those ordinary sequences which the uncivilised man regards as needing no explanation; afterwards, in the progress of culture, that of a system of thought always more or less modified and restricted by the increase of positive knowledge, and surviving only in greatly refined or greatly enfeebled forms, or only reviving at intervals of time.

Of the origin of animism perhaps no perfect account has yet been given. It can hardly be said to be obvious why, in uncultured races or individuals, there should arise that invariable tendency to represent natural forces as conscious and anthropomorphic. There is reason to believe, however, that the type of all the forms in which the tendency manifests itself, is to be discovered in the conception of the human soul. Evidently the notion of an animating, separable, and surviving soul commends itself as the ready explanation of many familiar phenomena, and the appropriate instrument of a philosophy which ascribes animation to nature at large; so that thus, according to the account given by Dr Tylor, primitive animism may be considered to have arisen simply from the evidence of men's senses, interpreted by the crude and childlike science of the prehistoric world. From the sight of life and death it was, he conceives, naturally inferred that every man has a life, or vital principle, the departure of which from his body causes death,—this idea being confirmed by apparent temporary departures, such as swoons and sleep. From the appearance of men seen in dreams and visions, it was not less cogently argued that every man has also a phantom likeness of his body, separable from it so as to appear to others at any distance, and continuing to exist and appear after the bodily death of its proper owner. Accordingly, the definition of the soul in primitive religion would, as in the lower existing religions it actually does, combine these leading qualities in the conception of an "apparitional soul," which is a thin, unsubstantial human image, the cause of life and thought in the individual it animates, capable of quitting his body for a time or altogether, and so leaving him insensible or dead, and when thus absent from the body appearing to other persons asleep or awake. From this conception, then, animism may reasonably be supposed to have had its origin, especially as other animistic doctrines exhibit such a distinct affinity and relationship to this of the apparitional soul, as almost amounts to a proof of direct derivation from it. The hypothesis being correct, it would, for instance, follow that the lower animals ought to be considered as having souls similar to human souls, inasmuch as they have life, and their phantoms are likewise seen. Moreover, though inert objects, such as clothes or weapons, have not life, yet their phantoms appear to men in dreams, and thus they must be considered as having something of the nature of souls, separable from their grosser part, and surviving its destruction. Now, in fact, both these ideas are recognised in the religions of the lower races. They come into special prominence in the savage and barbaric rite of sacrifice for the dead, where not only are wives and slaves slain to do service to their master's soul in the world of spirits, but horses and cattle are slaughtered to be spiritually transmitted thither, and clothes, ornaments, and other articles are destroyed, that he may wear and use the "object-souls" thus sent to him. The savage doctrine of a future state, presently to be referred to, also strikingly corroborates the theory of the phantom soul as the origin and centre of animistic thought.

There remains, however, the difficulty of understanding by what process this rudimentary doctrine of the soul has grown into the great system of developed animism: a system of thought so comprehensive as to hold all nature in a web of vital action and spontaneity; so multiform as to invent some new spirit-race for almost every fresh order of phenomena; so coherent as to create a perfect *plexus* of ideas that mutually support and interpret one another; finally, so persistent, that even its more extravagant developments can survive for ages in defiance of accurate knowledge. It is difficult to realise how exceedingly slow and gradual must have been that growth of positive science and its methods of verification, which has allowed a fanciful and little regulated philosophy to take root so firmly and cast its branches so far. Yet only by a great and connected development does it seem possible that animism could be so matured and extended. Regarding many, at least, of the varied forms of animistic belief, there is already sufficient evidence to make it probable that they have arisen by one continuous process of evolution, extending through the lower to the higher civilisation.

This evidence of continuity of development Dr Tylor represents as partly historical, and partly turning upon the principle of survival in culture. Thus, as among savage tribes, the soul is actually identified with the shadow or the breath, the use of such words as σκιά, πνεῦμα, *umbra*, *anima*, *shade*, and *spirit*, may be held to show the derivation of the civilised conception of the soul from the same primitive and savage idea. The primitive conception of the soul as consisting of a thin, vaporous, material substance, held its place in ancient philosophy and theology, being supported by such writers as Epicurus and Origen, and was only gradually superseded by the more modern belief of the soul's immateriality. The elves, fairies, goblins, &c., so well known in modern folk-lore, correspond to the nature-spirits and demons of the savage religions. In these cases there has been survival with considerable change; on the other hand, the continuity of animistic thought is likewise indicated by many instances in which an idea survives with little or no modification. Such instances are to be found in many old customs, and especially among peasants, whose notions of the spiritual world are often almost savage. Thus the ancient funeral sacrifice of the warrior's horse for him to ride into the other world, which was for the last time in Europe actually and officially done at Treves in 1781, is still kept up in form by leading the dead soldier's horse to his grave. The piece of money is still put in the hand of the corpse at an Irish wake; and in most countries of Europe may still be seen the pathetic custom of setting out offerings of food for the spirits of the departed. Sacrifices to the deities of wells and rivers, trees and rocks, have continued almost unchanged in the rudest districts of such countries as Russia. As a historical example, the primitive theory of convulsions, delirium, madness, &c., being caused by demoniacal possession lasted on among educated people through the Middle Ages, and has only been fairly suppressed by the modern medical schools.

Proceeding on the inference of continuous development, the same writer has attempted a classification of animistic doctrines as they appear in the religious philosophy of the lower and higher culture. The doctrine of souls, as distinguished from that of other spiritual beings, is first considered. It is found possible to trace the conception of the human apparitional soul in various beliefs concerning ghosts, wraiths, doubles, &c., which survive among civilised societies long after the soul has ceased to be conceived as material or ethereal. The notion of animal-souls, largely prevalent among savage tribes, still faintly survives in our own country. The doctrine of plant-souls seems long to have formed an important element in the religious philosophies of India; and even the doctrine of object-souls, which exercises unlimited dominion in savage religions, can still be traced as influencing some of the actions, though not, perhaps, the explicit opinions, of civilised men. Closely allied like these doctrines, to the primitive notion of the apparitional soul, is the belief in the soul's existence after death, which appears either as a doctrine of transmigration, describing the re-birth of souls in successive bodies, or in its more general and more important form as the doctrine of a future life. The latter, as commonly held by savage races, supposes the phantom souls of the departed either to remain here as hovering ghosts, or to be transported to some distant region, there to continue a life more or less similar to the present, but with little or no trace of moral retribution: in more advanced civilisations, however, this doctrine exercises the most powerful moral influence, by distinguishing the heaven of the good from the hell of the wicked. The primary doctrine of souls is next described as leading to the development of the doctrine of other spiritual beings, from the lowest ranks of demons and elves, up to the highest deities of the Pantheon. The life and action of the body being ascribed to a soul, all other phenomena of the universe were in like manner ascribed to soul-like beings or spirits, which are thus, in fact, personified causes. So disease among the lower races is accounted for by possession by demons, who are often themselves human souls, and who enter the bodies of their victims, causing all kinds of illness, and especially those phenomena of convulsion and delirium in which the patient seems actually animated by a spirit not his own. Other events and accidents of life are in the same way accounted for among savages as the acts of the demons, good or evil, whom they believe to pervade the universe; and as these beings are, more often than not, conceived to be souls of deceased men, the consequent worship of divine Manes is the principal religion of the lower state of civilisation. The doctrine of object-souls, expanding into the general doctrine of spirits conveying influence through material objects, becomes the origin of Fetichism and idolatry. Spiritual beings, under a thousand names, are multiplied upon the earth; not only those guardian spirits and hurtful demons directly influencing the lives of men, but others, far more numerous, with varied functions to discharge in the economy of the external world. To the lower races all nature being animated nature, every brook and well, every rock and glade, is peopled by nature-spirits; while Heaven and Earth, Sun and Moon, Rain and Wind and Thunder, are either themselves adored, or personified in the character of mighty nature-gods, such as Zeus, Apollo, or Poseidon,—spiritual beings who are, as it were, the great animating souls of their special phenomena. Among the lower races, also, there appears in a rudimentary form that antagonism between a good and evil deity, which forms the fundamental idea of Zoroastrism and Manichæism. Lastly, the conception of a Supreme Deity appears at a very early stage of civilisation, whether one of the great nature-deities, such as Heaven or Sun, is raised to this royal pre-eminence, or whether a being of the nature of a soul of the world, like the Great Spirit of the North American Indians, is venerated as Creator and Lord of the universe. Then, by a natural evolution, Monotheism is established.

Such, briefly sketched, is Dr Tylor's account of the development of animism, considered as the main principle of the philosophy of religion, throughout the various grades of civilisation. Whether, having shown many popular superstitions to be undoubted survivals from an ancient state of belief, he has been equally successful in proving a like derivation for doctrines recognised by modern religion, will be questioned by many who perceive the bearing of his conclusions upon the actual validity of theological tenets. It is proper to point out that he has noted one great distinction between the lower and higher animism, which consists in the absence of any distinctly ethical element in the spiritual philosophy of the less cultured races. Only at a comparatively late stage of their development do the moral feelings become associated with animistic beliefs.

The final decay of many forms of animistic belief, much more readily than the process of their development, admits of being traced with the aid of historical evidence. Indeed, the history of each of the sciences is a record of the progressive substitution of matter for spirit and law for spontaneity; and we can still witness the process of decay in various stages; for while certain sciences—like astronomy, since the time when Kepler imagined minds in the planets—have wholly exterminated the animism within their borders, there are others that have scarcely yet advanced so far—biology, for example, which is still familiar with "vital force" and final causes. Nor is the process commonly a rapid one: in many cases, as a world of illustration has been adduced to prove a declining spiritual conception may persist for a length of time, refined and modified into a "principle" or "essence," whose action, though still automatic like a spirit's, is also regular like that of a natural law. Among all civilised races, however, animism has long ceased to be known as the universal philosophy or explanation of nature, and its remaining manifestations are in great measure reduced to a secondary or rudimentary form. Thus animism survives in the imperfect theories of childhood; it survives also, as we have seen, in the superstitions of the uneducated; and as, in primitive societies, language and imagination fostered the development of spiritual myth, so animism, embodied in metaphor, remains in later civilisations as an important element, if not in truth the very substance of imaginative literature.

The process by which animism comes to be superseded by positive science is therefore familiar, both in its history and results. Regarding its real nature, however, the greatest difference of opinion exists, and there is raised one of the most interesting questions connected with animism—the question of its relation to metaphysics. According to the well-known doctrine of Comte, which, having since his time been expounded and illustrated by several of his followers, would now appear to be accepted by many even of those who do not profess themselves Positivists, animism passes into positive science *through* metaphysics. In support of this view there is pointed out, what has just been explained, that as knowledge progresses, anthropomorphic and animistic conceptions rarefy and sublimate into so-called essences or principles, with which conceptions metaphysical discussions are shown to be largely conversant. Systems of ontology betray their history by a hundred clinging vestiges of animism; and all the favourite ideas of the dialectician are to be traced in the symbolism of savage religions. The Platonic *ideas*, to take but a single instance, are closely represented by the *species-deities* of the North American Indians; while, even in the writings of the master himself, how animistic and mythical is the character they maintain. It is, therefore, concluded that metaphysics is little more than decaying animism, and that a large proportion of animistic theory, before being superseded by positive science, passes through the "metaphysical" stage. From this view of the nature of his science, and its relation to animism, the metaphysician, however, dissents. While admitting that degenerate "metaphysical" conceptions do exist, and that psychology and ontology, more perhaps than other sciences, are confused and retarded by their influence, he refuses to recognise these conceptions as metaphysical in any special or indeed admissible sense. The facts by which the Positivist seeks to prove that animism, as one inadequate explanation of nature, grows into metaphysics, another system of explanation almost equally unsatisfactory, the metaphysician rather regards as proving that metaphysics, a legitimate science, grows out of primitive animism by precisely the same process as other sciences. The discovery in savage or other religions, of dialectical ideas mythically expressed and explained, only confirms him in the belief that there does exist a class of phenomena which it is the business of the science of metaphysics to investigate, since even mythical explanations are seldom formed, unless in the presence of some real problem calling for solution; and he contends that in this way the subject matter of metaphysical science, though long overgrown and encrusted with animistic conceptions, does gradually shine through and assert itself in the light of positive knowledge. If these arguments then be allowed, metaphysics is no decaying animism, but rather a science in the act of struggling free from animism; and animism itself, though often passing in its decay through a phase misnamed metaphysical, is quite improperly represented as undergoing any transformation into metaphysics.

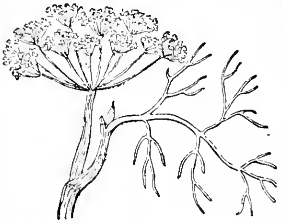
Reviewing the conclusions countenanced by what evidence we possess touching the nature and history of the doctrine of spiritual beings, we find that while it is possible, and even necessary, to regard animism as a system of primitive philosophy extending through various forms into the higher civilisations, yet this view being for the most part unsupported by direct historical evidence, and depending largely on the inference of a close analogy between primitive and savage thought, is in great measure confessedly theoretical, leaving much room for dispute, both as to the extent to which animistic beliefs have been transmitted and modified by a regular, continuous, and uninterrupted process, and as to the conditions which, in special instances, have led to their formation and development, or disappearance and decay. A theory that represents, not only the extravagances of mythology and superstition, but indeed all that we call spiritual, nay, all that we name divine, as but the fruit of a natural anthropomorphic tendency, much more appropriate to savage than to civilised life, is, it is manifest, in thorough inconsistency with many widely accepted doctrines of philosophy and theology. Regarding the importance of the inquiry there is, however, no dispute. Spiritual philosophy has influenced every province of human thought; and the history of animism, once clearly traced, would record the development, not of religion only, but of philosophy, science, and literature. (A. O. L.)

ANIMUCCIA, GIOVANNI, musical composer, was born at Florence in the last years of the 15th century. At the request of St Filippo Neri he composed a number of *Laudi*, or hymns of praise, to be sung after sermon, which are noteworthy as furnishing the rudimentary form out of which the Oratorio was developed. In 1555 he was appointed "maestro di capello" at St Peter's, an office which he held until his death in 1571. He was succeeded by the more celebrated Palestrina, who had been his friend and probably his pupil. It is impossible to say to what stage Animuccia brought the oratorio form, as no specimens of his *laudi* are now extant. The manuscript of many of his other compositions is still preserved in the Vatican Library. His chief published works were *Madrigali e Motetti a quattro e cinque voci* (Ven. 1548) and *Il primo Libro di Messe* (Rom. 1567). From the latter Padre Martini has taken two specimens for his *Saggio di Contrapunto*. Paolo Animuccia, a brother of Giovanni, was also celebrated as a composer.

ANIO, or ANIEN, the modern *Teverone*, a river of Italy which rises in the Apennines, and, flowing first N.W. and then S.W., joins the Tiber a little above Rome. It forms a beautiful cascade at Tivoli. The Anio supplied Rome with water by two aqueducts, the Anio Vetus, constructed about 270 B.C., and the Anio Novus, completed, 48 A.D., by Claudius. The Digentia of Horace is one of its tributaries. See AQUEDUCT and TIVOLI.

ANISE, *Pimpinella Anisum*, is an umbelliferous plant found in Egypt and the Levant, and cultivated on the Continent of Europe. It is used medicinally as an agreeable aromatic. The officinal part of the plant is the fruit which consists of two united carpels, called a cremocarp. It is known by the name of aniseed, and has a strong aromatic taste and a powerful odour. By distillation the fruit yields a volatile, oily matter known as oil of anise. It is used as a carminative, and is also employed in the manufacture of liqueurs. The anise of the Bible (Matt. xxiii. 23) is *Anethum graveolens*, or dill (see fig.), a native of the south of Europe and of Egypt, and also found near Astracan, at Buenos Ayres, and at the Cape of Good Hope The name Dill is derived from an old

Norse word meaning to soothe, referring to its carminative qualities in allaying pain. It is one of the garden plants of which the Pharisees were wont to pay tithes. It is used in pickles and soups. The star-anise of liqueur-makers is the produce of a totally different plant, *Illicium anisatum*, belonging to the Natural Order Magnoliaceæ, sub-order Wintereæ. It receives its name from its flavour, and from its fruit spreading out like a star.



ANJÁR, a fortified town of Hindustán, and the capital of a district of the same name in the native state of Cutch, lies in 23° 6′ N. lat., 70° 3′ E. long. The country is dry and sandy, and entirely depends on well irrigation for its water supply. The town is situated nearly 10 miles from the Gulf of Cutch. It suffered severely from an earthquake in 1819, which destroyed a large number of houses, and occasioned the loss of several lives. In 1820 the population was estimated at 10,000. The town and district of Anjar were both ceded to the British in 1816, but in 1822 they were again transferred to the Cutch Government in consideration of an annual money payment. Subsequently it was discovered that this obligation pressed heavily upon the resources of the native state, and in 1832 the pecuniary equivalent for Anjár, both prospectively and inclusive of the arrears which had accrued to that date, were wholly remitted by the British Government.

ANJENGO, once a British factory and fortress, now a small sea-port town of India, in Travancore, nearly encircled by a deep and broad river, at the mouth of which it is situated. It lies in 8° 40′ N. lat., 76° 49′ E. long. The fort was built by the English in 1684, and retained till 1813, when the factory was abolished on account of the useless expense attending it. Anjengo is infested with snakes, scorpions, and centipedes, those animals finding shelter in the matted leaves of the cocoa-tree with which the houses are mostly thatched. Anjengo is celebrated for the best coir cables on the Malabar coast, manufactured from the fibre of the Laccadive cocoa-nut. It also exports pepper, cotton cloths, and drugs.

ANJER, a sea-port town of the Dutch East Indian island of Java, situated on the Strait of Sunda, 18 miles W. of Batavia. It is protected by a fort, and besides carrying on a considerable trade in Eastern curiosities, supplies passing vessels with fresh water and provisions. The population is considerable, but its amount is not known.

ANJOU, one of the thirty-six ancient provinces of France, approximately equivalent to the modern department of Maine and Loire. It was bounded on the N. by Maine, which separated it from Normandy; E. by Touraine; S. by Poitou; and W. by Brittany. It was, as Mr Freeman has remarked, altogether lacking in geographical individuality, and owed its somewhat prominent position in history to the character and fortunes of its counts and dukes. By the ancient chronicler of Anjou the origin of the countship is referred to a certain Tertullus, who owed his elevation from an humble rank to Charles the Bald; but the first person history lays hold of is Ingelgar, who lived about 870, and obtained possession of that portion of the subsequent province which lies between the Maine and the Mayenne. He was followed in succession by Fulk the Red (888); Fulk the Good (938), author of the proverb that an unlettered king is a crowned ass; Geoffrey Grisegonelle, or Grey-Tunic (958); Fulk Nerra, or the Black, famous as a warrior, and on account of his pilgrimages, by way of penance, to the Holy Sepulchre; Geoffrey Martel, a vigorous but unsuccessful opponent of William the Conqueror; his nephews, Geoffrey the Bearded and Fulk Rechin, from the latter of whom we have an interesting historical fragment, giving an account of his ancestors and defending his own conduct (D'Achery, *Spicilegium*, folio edition, vol. iii.); Fulk Nerra II.; and Geoffrey Plantagenet, who united Anjou and Maine, and —by his marriage with Matilda of England—Normandy also into one dominion. When his son became (1154) king of England, as Henry II., these various provinces passed into the power of the English crown, but were forfeited by King John (1204) to Philip Augustus of France. Henry III. demanded restitution, but did little in support of his demand; and Anjou soon passed into the hands of Philip, son of Louis VIII., and from him to Charles, the brother of Louis, who by his exploits in Italy made the name of Charles of Anjou famous, and established the house of Anjou on the throne of Naples (1266–1285). His son, Charles II., king of Naples, nicknamed *il Zoppo*, or the Lame, gave the investiture of Anjou and Maine to his son-in-law, Charles of Valois, younger son of Philip the Bold; and from 1290 the counts of Valois took the title of dukes of Anjou and counts of Maine. In 1328 the son of Charles of Valois became king of France, as Philip VI., and united the duchy of Anjou to the crown. King John in 1356 bestowed it on his son Louis. The Anjou line ended in the unfortunate René (noticed below), who was deprived of his duchy by Louis XI. of France, or, more strictly, in his brother Charles, who died in 1481. Meanwhile old René's daughter Margaret, who was made of sterner stuff than her father, was battling with more than a woman's valour for the rights of her son in England. From this time onward the title of duke of Anjou has been borne, without implying any territorial sovereignty, by Charles VIII. of France, by each of the four sons of Henry II., by the second son of Henry IV., by the two sons of Louis XIV., by his grandson (Philip V. of Spain), and by his great-grandson (Louis XV.) Charles, a nephew of Charles of Naples, obtained the throne of Hungary in 1308, and was succeeded by his son Louis the Great, who also became king of Poland; but the same fatality of failure in the male line also befell this branch of the house of Anjou. (See Freeman's *Norman Conquest*, vol. ii. p. 267; D'Achery, *Spicilegium*, vol. iii.)

ANJOU, René, Duke of, was the second son of Duke Louis II., and succeeded his brother Duke Louis III. He was born at Angers in 1408, and brought up by his uncle, Louis of Bar, who, in 1419, contracted a marriage between him and Isabella, heiress of Lorraine, and, in 1430, left him in possession of his duchy. On the death of Charles of Lorraine in 1431, René was acknowledged as his successor, but he had soon to defend himself against the claims of the count of Vandemont, who was supported by Philip of Burgundy. The battle of Bouligneville decided in favour of the count, and René was taken prisoner to Dijon by Philip. In 1432, however, he was conditionally released, and in the following year was confirmed in the duchy of Lorraine by the Emperor Sigismund. In 1435, while again, according to the conditions of his release, in the custody of Philip, he became, by the death of his brother, duke of Anjou and count of Maine, and a little later, received the offer of the inheritance of the queen of Naples. His endeavours to enforce his claims on the Neapolitan kingdom were ultimately futile, and he quitted Italy in 1442. Three years afterwards he married his daughter Margaret to Henry VI. of England, and thus increased the influence, though hardly the prosperity of his house. On the death of his wife in 1453, he bestowed the duchy of Lorraine on John of Calabria, his only surviving son. He himself retired to Provence, where henceforth, with but occasional interruption, he led a simple quiet life, amusing himself with the writing of verses and the painting of miniatures, the cultivation of flowers, and the keeping of wild animals. Thus occupied, he exhibited a philosophical submission to the changes brought about by the artful schemes of his less pacific neighbours, until he was at last reduced to an ignoble dependency on the good-will and pleasure of Louis of France, without the liberty of even bequeathing his possessions to any one but the king He died at Aix in 1480, followed by the regret of his subjects, who afterwards held him in remembrance as "The Good King René."

ANKARSTRÖM, Johan Jakob, the assassin of Gustavus III, king of Sweden, was descended from an honourable family, and was born in 1759. After having been for some time at court as a page, he entered the army, but left after a few years with the honorary rank of captain. He is said to have been concerned in some treasonable projects, and to have been pardoned by the king, but the story has not sufficient authority. The Swedish nobles were about this time violently opposed to the king, who, by the aid of the other orders of the state, had wrested their power from them, and was now ruling despotically. This dislike was increased by the *coup d'état* of 1789, and by the king's known desire to interfere in favour of Louis XVIII. of France. Ankarström, a man of strong passions and violent temper, resolved upon the assassination of Gustavus, and communicated his intention to the disaffected nobles, and among others, to Counts Horn and Ribbing, who would willingly have undertaken the deed themselves. After some ineffectual attempts to seize the king's person, a favourable opportunity offered itself. A masked ball was held at Stockholm on the 16th March 1792, which the king attended, though he had been warned against doing so by an anonymous letter. By a preconcerted signal, Count Horn indicated his victim to Ankarström, who fired and inflicted a mortal wound. The murderer was identified by the discharged pistol, thrown down in the ball-room, and was arrested. He did not attempt to deny his crime, but declared that he had no accomplices. After a long trial he was condemned, was publicly beaten on three successive days, had his right hand cut off, and was finally beheaded and quartered. He endured his sufferings with the greatest fortitude, and seemed to rejoice in having rid his country of a tyrant. His principal accomplices were imprisoned for life.

ANKLAM, or Anclam, a town of Prussia, in the province of Pomerania, situated on the Peene, 6 miles from its mouth in the Kleine Haff, and 47 N.W. of Stettin, with which it is connected by railway. The fortifications of Anklam were dismantled in 1762, and have not since been restored, although the old walls are still standing; formerly, however, it was a town of considerable military importance, which suffered severely during the Thirty Years' and the Seven Years' Wars; and this fact, together with the repeated ravages of fire and of the plague, has made its history more eventful than is usually the case with towns of the same size. It does not possess any remarkable buildings, although it contains several, private as well as public, that are of a quaint and picturesque style of architecture. The Peene is navigable up to the town, which has a considerable trade in its own manufactures, as well as in the produce of the surrounding country, while some shipbuilding is carried on in wharves on the river. The chief manufactures are linen and woollen goods, leather, beer, and soap. Anklam formerly bore the names Wendeuburg and Tanglim. Population in 1871, 10,739.

ANKOBAR, or Ankober, the capital of the kingdom of Shoa in Abyssinia, situated in lat. 9° 34′ N. and long. 39° 35′ E., on a mountain about 8200 feet above the level of the sea. The appearance of Ankobar is somewhat peculiar; its houses, ill-built wooden structures, with conical thatched roofs, are irregularly dotted over the side of the hill; a rude fortification of stakes and branches protects the upper portion of the town, while the palace, a more pretentious, but very ugly stone building, crowns the summit. Ankobar enjoys many natural advantages, its climate especially being remarkable for mildness and salubrity. Its population is about 5000, but during the residence of the court it rises to 15,000.

ANNA, Ana, or Anah, a town of Turkey in Asia, situated on the right bank of the Euphrates, about 160 miles N.W. of Baghdad. It is an open, defenceless place, consisting chiefly of a single street, which extends for several miles along a narrow strip of land that lies between the river and a ridge of rocky hills. The houses are separated from each other by beautiful and fertile gardens filled with fruit trees, and in the river, facing the town, is a succession of equally productive islands. The most easterly of these islands contains the ruins of the old castle, while the remains of the ancient *Anatho* extend from this island for about two miles down the left bank of the Euphrates. Coarse cloth is almost the only manufacture at Anna.

ANNA CARLOVNA, who for a few months held the position of regent in Russia, during the minority of her son Ivan, was the daughter of Catherine, sister of the Empress Anna Ivanovna, and was born in 1718. In 1739 she married the duke of Brunswick Wolfenbüttel, and their son Ivan was, in 1740, adopted by the empress and proclaimed heir to the throne. A few days after this proclamation the empress died, leaving directions regarding the succession, and appointing her favourite Biron as regent. Biron, however, had made himself an object of detestation to the Russian people, and Anna Carlovna, with the assistance principally of the able but intractable Munich, had little difficulty in overthrowing his power. She then assumed the regency, and took the title of grandduchess; but she knew little of the character of the people with whom she had to deal, was utterly ignorant of the approved Russian mode of government, and speedily quarrelled with her principal supporters. In December 1741, Elizabeth, daughter of Peter the Great, who, from her habits, was a favourite with the soldiers, excited the guards to revolt, overcame the slight opposition that was offered, and was proclaimed empress. Ivan was thrown into prison, where he soon afterwards perished. Anna and her husband were banished to a small island in the River Dwina, where, in 1745, she died in childbed. Her husband survived her for many years.

ANNA COMNENA, daughter of the Emperor Alexius Comnenus I., was born 1st December 1083. She was her father's favourite, and was carefully trained in the study of poetry, science, and Greek philosophy. With a mind superior to the effeminacy and voluptuousness of the court in which she was educated, she cultivated literature and sought the acquaintance of the more eminent philosophers of the period. But wise and studious as she was, she was also intriguing and ambitious. Having married an accomplished young nobleman, Nicephorus Bryennius, she united with the Empress Irene in attempting to prevail upon her father during his last illness to disinherit his son, and give the crown to her husband. The affectionate virtue of the father prevailed over female address and intrigue; but this only stimulated the ambition of Anna. She entered into a conspiracy to depose her brother; and when her husband displayed timidity in the enterprise, she exclaimed that "nature had mistaken their sexes, for he ought to have been the woman." The plot being discovered, Anna forfeited her property and her fortune, though, by the clemency of her brother, she escaped with her life. Excluded by her base conduct from the enjoyments of court, she employed her solitude in writing the *Alexiad*—a history, in Greek, of her father's life and reign. The production is still extant, and forms part of the celebrated collection of the *Byzantine Historians*. Her style is extravagantly rhetorical, diffuse, and panegyrical. In her account of the first Crusade she is often at variance with the Latin authorities. The *Alexiad*, in fifteen books, was first published at Augsburg in 1610; but the best edition is that of Schopen, with a Latin translation (Bonn, 1839, 2 vols. 8vo), and Schiller in his *Historic Memoirs* gives a German translation.

ANNA IVANOVNA, Empress of Russia, daughter of Ivan, brother of Peter the Great, was born in 1693, and married in 1710 to the duke of Courland, who died the following year. After the death of Peter II., in 1730, the imperial council offered the vacant throne to Anna on the following conditions:—She was to govern according to the decisions of the supreme council, and she was not allowed, without its consent, either to declare war or to conclude peace, to impose new taxes, to grant any important office of the state, to dispose of crown lands, to contract a matrimonial alliance, or to nominate a successor to the throne. She was also not to punish any noble, or to confiscate any one's property without a legal sentence. Anna signed these conditions without any demur; but after her arrival at Moscow, a numerous party, jealous of the authority which this constitution, imitated from that of Sweden, gave to the supreme council, or rather to the families of the Princes Dolgorouki and Galitzin, of whose members it was chiefly composed, petitioned the empress to assume the autocracy of her predecessors. Anna immediately complied with this request, and the framers of the constitution either were banished to Siberia, or perished on the scaffold. Russia was governed in a most tyrannical and oppressive manner during the whole reign of Anna by her favourite Biren, who was made by her influence duke of Courland. According to Russian authorities, 20,000 victims of Biren's tyranny perished during Anna's reign of six years, and amongst them persons belonging to the highest ranks in the country. The principal events of Anna's reign were the voluntary restoration, in 1732, to Shah Nadir of the Russian provinces, Shirvan, Ghilan, and Mazanderan, acquired by Peter the Great, but which caused more expense than they yielded revenue to Russia; a Chinese embassy at St Petersburg, the only one that was ever sent to Europe; the assistance given to the elector of Saxony and king of Poland, Augustus III., against his competitor Stanislaus Leszczinski, supported by France; a Russian army sent to the assistance of the Emperor Charles VI. against France; a war with Turkey from 1736 to 1739, which, notwithstanding several successful campaigns, gave no advantage to Russia at the conclusion of peace; and an advance made into Central Asia by the establishment of the Russian protectorate over the khan of the Kirghises, who, with the assistance of Russian officers, conquered Khiva, but failed to maintain himself there. Anna died in 1740. Her reign is considered as a period of transition from the old Muscovite semi-barbarian manners to the polish, though not the civilisation, of the West.

ANNA, Baldasarre d', a painter of some repute, who flourished during part of the 16th and 17th centuries. He was born at Venice, probably about 1560, and is said to have been of Flemish descent. The date of his death is uncertain, but he seems to have been alive in 1639. For a number of years he studied under Leonardo Corona, and on the death of that painter completed several works left unfinished by him. In the opinion of many judges he surpassed his master in richness and mellowness of colour, though he was inferior to him in design. His own activity seems to have been confined to the production of pieces for several of the churches and a few of the private houses in Venice; and though there exists no accurate list of his works, the old guide-books and descriptions of the city notice a considerable number of paintings by him. Scarcely any of these, however, have survived to the present time.

ANNABERG, a town of Saxony, situated in the Erzgebirge, about 1830 feet above the level of the sea, and at a distance of 18 miles south from Chemnitz, with which it is connected by railway. The chief importance of Annaberg is derived from its large lace and ribbon manufactories, the latter of which were first established in the town by Belgian Protestants, who were driven from their country by the tyranny of the duke of Alva. There are also extensive and valuable silver, tin, and cobalt mines in the neighbourhood. Population, 11,693.

ANNALS (*Annales*, from *annus*, a year), a concise historical record in which events are arranged chronologically, year by year. The chief source of information in regard to the annals of ancient Rome is a passage in Cicero (*De Oratore*, ii. 12, 52), which has been the subject of much discussion. He states that from the earliest period down to the pontificate of Publius Mucius Scævola (*circa* 131 B.C.), it was usual for the Pontifex Maximus to record the events of each year on a white tablet (*album*), which was exhibited in an open place at his house, so that the people might read it. These records were called in Cicero's time the *Annales Maximi*. After the pontificate of Publius, the practice of compiling annals was carried on by various unofficial writers, of whom Cicero names Cato, Pictor, and Piso. The *Annales* have been generally regarded as the same with the *Commentarii Pontificum* cited by Livy, but there seems reason to believe that the two were distinct, the *Commentarii* being fuller and more circumstantial. The nature of the distinction between annals and history is a subject that has received more attention from critics than its intrinsic importance deserves. The basis of discussion is furnished chiefly by the above quoted passage from Cicero, and by the common division of the work of Tacitus into *Annales* and *Historiæ*. Aulus Gellius, in the *Noctes Atticæ* (v. 18), quotes the grammarian Verrius Flaccus, to the effect that history, according to its etymology (ἱστορεῖν, *inspicere*, to inquire in person), is a record of events that have come under the author's own observation, while annals are a record of the events of earlier times arranged according to years. This view of the distinction seems to be borne out by the division of the work of Tacitus into the *Historiæ*, relating the events of his own time, and the *Annales*, containing the history of earlier periods. It is more than questionable, however, whether Tacitus himself divided his work under these titles. The probability is, either that he called the whole *Annales*, or that he used neither designation. (See Tacitus.) So far as the distinction between annals and history is real, it seems to arise out of the more restricted conditions imposed upon the annalist as compared with the historian. A narrative strictly annalistic must necessarily be a mere register of isolated facts, and not a record of historical processes. Confined at each stage within the narrow limit of a single year, it cannot trace the progress of events or exhibit their connection and interdependence, as is done in history. (See on this subject an ingenious though somewhat fanciful paper by Niebuhr contributed to the *Rheinisches Museum*, and translated by Thirlwall in the Cambridge *Philological Museum*, vol. ii.) In modern literature the title annals has been given to a large number of standard works which adhere more or less strictly to the order of years. The best known are Grotius's *Annales et Historia de Rebus Belgicis* (Amst. 1557), written in imitation of Tacitus; Baronius's *Annales Ecclesiastici*, comprising the first twelve centuries of the Christian era; Hailes's *Annals of Scotland from the Accession of Malcolm III. to the Accession of the House of Stuart;* Chambers's *Domestic Annals of Scotland;* and the *Annales de Chimie*, founded in 1789 by Lavoisier and others, and continued, with two interruptions, down to the present time.

ANNAMABOE, or ANAMABOE, a British fort and town on the Gold Coast of Africa, about 10 miles E.N.E. of Cape Coast Castle. It exports palm oil, ivory, gold dust, pea nuts, and Guinea grains; and in return its imports of manufactured goods are considerable. The town suffered severely during the invasion of the Ashantees in 1807, but the fort, although garrisoned only by a few soldiers, resisted the whole Ashantee host. Population about 4500.

ANNAN, a royal and parliamentary burgh of Scotland, in the county of Dumfries, situated on the river Annan, nearly two miles from the Solway Firth, and about fifteen from Dumfries. It is a well-built town, containing a town hall, a parish church, several dissenting chapels, and an excellent academy. The river Annan which has been embanked, is navigable for vessels of 300 tons up to within half a mile of the town, and for vessels of 60 tons to the bridge, a fine structure of three arches built in 1824. Annan is a station on the G. and S.-W. Railway, and is connected with the main line of the Caledonian Railway, and also with England, by the Solway Junction branch which crosses the firth by means of a very strong viaduct. The principal manufactures are cotton, ropes, and cured hams; shipbuilding and salmon fishing are also carried on, while there is a considerable trade with England, the chief exports being cured hams, cattle, sheep, and grain. The town, which is governed by a provost and fourteen councillors, including three bailies, unites with Dumfries, Kirkcudbright, Lochmaben, and Sanquhar, in returning one member to parliament. In 1871 the population of the royal burgh was 4174, of the parliamentary, 3172.

ANNAN, a river rising near the source of the Tweed, in the range of hills that lies on the confines of the counties of Dumfries, Lanark, Peebles, and Selkirk. About two miles beyond Moffat it receives two large tributaries,—the Moffat Water, which flows westward from Loch Skene, a mountain lake in the north-eastern corner of Dumfriesshire, and the Evan Water, which flows eastward from the upper part of Lanarkshire. The Annan has a total length of about 40 miles, and below its junction with the Moffat and the Evan it is joined by the Kennel Water from the west and the Dryfe Water from the east. Annandale was once the name of a stewartry which comprehended a large portion of Dumfriesshire.

ANNAPOLIS, a seaport town of the United States, the capital of Maryland, situated on the Severn, about 2 miles from its mouth in Chesapeake Bay, and about 25 in a direct line from Washington, with which it is connected by railway. It is a neat, regularly-built place, but the trade which at one time seemed likely to enrich it has been transferred almost entirely to Baltimore, and Annapolis is now little more than the political capital of the state. It contains handsome Government buildings, a college, and the United States Naval Academy, which was established at Annapolis in 1845, and was for a time removed to Newport, Rhode Island. Providence, as Annapolis was first called, was founded in 1649, but it did not get a charter until 1708, when it also received its present name in honour of Queen Anne. It has been the seat of government since 1689. Population in 1870, 5744.

ANNAPOLIS, a town of Nova Scotia, capital of Annapolis county, and up to 1750 of the whole peninsula, situated on an arm of the Bay of Fundy, at the mouth of a river also called Annapolis, 95 miles west of Halifax. Annapolis is one of the oldest settlements in North America, having been founded in 1604 by the French, who called it Port Royal; it was finally captured by the British in 1710, and was ceded to them by the treaty of 1713. It possesses a good harbour, but its trade at present is small. Apples of a very fine quality are grown in the surrounding country. Population, 1500.

ANN ARBOR, a town of the United States, the capital of Washtenaw county, Michigan, situated upon the Huron, about 40 miles west of Detroit, with which it is connected by the Michigan Central Railway. The town, which is healthy and well built, is a place of considerable commercial importance, its chief manufactures being iron, wool, and flour, while the trade in the produce of the surrounding district is large and valuable. It is the seat of the university of Michigan, a liberally-endowed institution, founded in 1837, and at present containing three subsidiary colleges devoted to legal, medical, and literary studies respectively, with a total attendance, in 1870, of 1072 students. The college buildings are large and pleasantly situated, and the university possesses a library, an observatory, and a chemical laboratory. The population of Ann Arbor in 1870 was 7363.

ANNATES. As early as the 6th century it began to be customary for those who were ordained to ecclesiastical offices to pay a fee or tax to the ordaining authorities; and this tax at length amounted to a half or the whole of a year's income. When, in course of time, the Roman See had appropriated the right of consecration, the money was paid into the Papal treasury, not, according to the defenders of the system, as a remuneration for the benefice conferred, but as a natural contribution to the maintenance of the Pope and his ecclesiastical government. These *annates*, or first-fruits, were of different kinds, though the chief features were the same in all. *First*, When a bishop, archbishop, or abbot received his investiture, he paid to the Pope a year's revenue of his new benefice (*servitia communia*); *Secondly*, If his benefice was one of those "reserved" by the Pope, he handed over to the Papal treasury the annates paid to him by those whom he at any time collated to livings in his diocese (*annalia, medii fructus, jus deportuum*); *Thirdly*, According to a bull of Paul II. in 1469, if benefices were united to certain communities, the annates were only to be paid every fifteen years, and not at every presentation (*quindenia*); and, *Fourthly*, A small addition was made to the *servitia communia* as a kind of notarial fee (*servitia minuta*). It must not be supposed that this system ever was worked with absolute uniformity and completeness throughout the various parts of the Papal domain. There were continual disagreements and disputes: the central authorities endeavouring to maintain and extend this most important of their financial schemes, and the subordinate ecclesiastics doing their best to get rid of the impost altogether, or to transmute it into some less objectionable form. The subject frequently became one of national interest, on account of the alarming amount of specie which was thus drained away, and hence numerous enactments exist in regard to it by the various national governments. In England the annates, which had previously been paid for the most part to the archbishop of Canterbury, were claimed by John XXII. (1316–1334) for three years, and permanently usurped by his successors till the time of Henry VIII., when, in 1531, their collection was prohibited. At that time the sum amounted to about £3000 a year. On the completion of the Reformation, the annates were, along with the supremacy, bestowed on the crown; but in February 1704 they were appropriated by Queen Anne to the assistance of the poorer clergy, and thus form what has since been known as "*Queen Anne's bounty.*" The amount to be paid was originally regulated by a valuation by the bishop of Norwich in 1254, later by one instituted in 1292, which in turn was superseded by the *Liber Regis* of 1535. In France, in spite of royal edicts,—like those of Charles VI., Charles VII., Louis XI., and Henry II.,—and even denunciations of the Sorbonne, the custom held its ground till the famous decree of the 4th of August during the Revolution of 1789. In Germany it was decided by the concordat of Constance, in 1418, that bishoprics and abbacies should pay the *servitia* according to the valuation of the Roman chancery in two half-yearly instalments. Those benefices only were to pay the *annalia* which were rated above 24 gold florins; and as none were so rated, the annalia fell into disuse. The Basle Council (1431–1443) wished to abolish the *servitia*, but the concordat of Vienna (1448) confirmed the Constance decision. The Congress of Ems (1786) also declared against them; but they continued to be paid till 1803, when, to indemnify the powers that had sustained territorial loss through the recent wars, a very great amount of ecclesiastical property was secularised. In some parts of Germany, the payment of annates is still made under particular concordats. In Scotland *annat* or *ann* is half a year's stipend allowed by the Act 1672, c. 13, to the executors of a minister of the Church of Scotland above what was due to him at the time of his death. This is neither assignable by the clergyman during his life, nor can it be seized by his creditors.

ANNE, Queen of Great Britain and Ireland, was born on the 6th of February 1664. She was the second daughter of James Duke of York, afterwards James II. She was only seven years old when her mother, Anne Hyde, died, having previously professed adherence to the Church of Rome, a step which was immediately imitated by her husband. The duke, however, had to allow his daughters, the princesses Mary and Anne, to be brought up as Protestants; and Anne always continued to be attached, zealously and even bigotedly, to the Church of England. In her twentieth year she was married to Prince George, the brother of the King of Denmark. In the establishment then formed for her, a place was given, on her own earnest desire, to her early playfellow Lady Churchill, afterwards Duchess of Marlborough; and this ambitious and imperious woman, acquiring rapidly an irresistible authority over the feeble mind of the princess, thenceforth ruled her absolutely for more than twenty years. Not long afterwards, when the Duke of York had become king, he made repeated attempts to convert the princess Anne to his own creed; he engaged that, if she would become a Roman Catholic, she should be placed in the line of succession to the throne before her elder sister Mary. Prince George appears to have received those overtures favourably; but he, an indolent and goodnatured man, who cared for nothing but good eating and field-sports, never had any influence over his wife. She remained firm in her Protestantism, lived in retirement during the whole of her father's reign, and did not allow her opinions or feelings any further vent than that which they found in her private correspondence with the Princess of Orange. When, in 1688, James's queen gave birth to a son, the sisters took a lively interest in the suspicions and inquiries that arose; and Anne was easily led to believe that the child was supposititious; though later in her life she must have been convinced that he was really her brother. Before the landing of the Prince of Orange Prince George was pledged to join him; and his wife and Lady Churchill abandoned King James on the first opportunity.

From the Revolution till the death of William III., Anne's way of life was as quiet and obscure as it had been during the reign of her father. She did, indeed, on the prompting of her favourite, acquiesce in the act of the convention-parliament, which, postponing her place in the succession, gave the throne to William in case he should survive Mary. But the sisters soon quarrelled, and never were reconciled. The misunderstanding began in trifling questions of etiquette, quite fitted to the calibre of both of the royal minds; but considerations of real importance soon compelled the king himself to interfere. The Churchills, traitorous to their new sovereign, as they had been to the old, were known to be intriguing for the restoration of James; and they induced Anne to write secretly to her father, and declare repentance for her desertion of him. Even when William dismissed Marlborough from all his places, the princess obstinately persisted in retaining his wife in her household. After Queen Mary's death the king and his sister-in-law went through the forms of a reconciliation; but there was no confidence on either side; and indeed the secret correspondence with Saint Germains was still carried on. The state of the succession to the crown threatened new difficulties. Anne had seventeen children, but most of them were still-born; and the Duke of Gloucester, the only one who survived infancy, died in 1700 at the age of eleven. The Jacobites, however, were unable to prevent the passing of the Act of Settlement, which placed the Electress of Hanover after Anne in the succession to the crown.

On the 8th of March 1702, Anne became queen of England by the death of William, being then thirty-eight years of age. Into her short reign there were crowded events possessing vast importance, both for the British Empire and for the whole of Europe; and her name is customarily associated with one of the most characteristic epochs in the history of English literature. Marlborough and Peterborough commanded her armies; her councils were directed in succession by Godolphin and Somers, by Harley and St John; Berkeley and Newton speculated and experimented; and the "wits of Queen Anne's time" were mustered, in poetry and in prose, under such chiefs as Prior and Pope, Swift, Addison, and Steele, Arbuthnot and Defoe. But no sovereign could have exerted less of real and personal influence than Queen Anne did, either on the national polity or on the national enlightenment. A blessed thing it was that she should have been thus powerless. For, beyond her own epicurean comforts, and the petty ceremonial of her court, there were just three ideas which her narrow and uninstructed intellect admitted: each of these ideas was full of danger to the peace and happiness of the state; and each of them was cherished by her with the hereditary stubbornness of a Stuart. She was as eager as any one of her race to enlarge the prerogatives of the crown: her father's devotion to the Church of Rome was not stronger than was her desire to increase the power of the Church of England; and she never ceased to wish earnestly that her exiled brother should be her successor on the throne. In no stage of Anne's reign was even the last of these designs impracticable: there were always able statesmen inclined to lead the way; and more than once the tide of public opinion set towards absolutism, both political and ecclesiastical. The queen, however, was not only dull and ignorant, but also indolent, fond of flattery, and accustomed from her youth to let herself be guided by stronger and more active minds than her own. Whatever her wishes might be, her actions were ruled by her female favourites. Fortunately the earlier of her two directresses, a woman of extraordinary force of character, was both willing and able to keep in check the queen's private inclinations: not less fortunate was it that the sway exercised by the next possessor of the royal favour was speedily cut short by her mistress's death. The course of English history might have flowed less smoothly if the Duchess of Marlborough and her husband had not become convinced that their own interest lay in supporting the principles of the Revolution; and those principles might have sustained a rude shock, if Mrs Masham and her Jacobite allies had been allowed a few months longer to mature the queen's plans and their own.

The reign of Queen Anne, lasting for twelve years, falls naturally into two unequal periods.

During the first of these, the Duke of Marlborough was paramount in the houses of parliament, and his wife in the royal closet. A ministry of Tories was formed on the queen's accession; but the leaders of it were Marlborough and Godolphin, who immediately began to edge off from their party. The principal measures were, from the beginning, in substantial conformity to the policy of King William: the war with France, hardly resisted then by any part of the nation, was prosecuted with ardour and success; and the victories of Oudenarde, Ramillies, and Blenheim, gained by the consummate generalship of Marlborough, made England formidable and illustrious throughout Europe. In the internal affairs of the kingdom, Whig principles for a time prevailed more and more; the party acquired a decided majority in the House of Commons; and the ministry came to be composed almost entirely of Whigs, some of the Tories being dismissed, and others, like the two leaders, showing the accommodating flexibility of opinion which was so rife among the statesmen of that slippery age. The union of England and Scotland was carried through in the face of many difficulties; and, while the proceedings of the ministry in the matter were by no means perfectly pure, the measure owed its success mainly to the independent and honourable assistance of the best man among the Whigs, the accomplished and patriotic Lord Somers. During several years, in short, barriers were gradually and firmly built up against the old system and the old parties. But other days were at hand. The domineering favourite of the queen presumed rashly on her power, and offended the self-esteem of her mistress. Mrs Masham, a poor relation of the duchess, whom she had introduced into the royal household, soothed Anne's fretful temper, gratified her vanity, and quickly, though secretly, acquired her confidence and affection; and, under the guidance of the new favourite, and her prompter Harley, the queen was encouraged to hope for the attainment of all her most cherished aims. The state of public opinion underwent a corresponding change. Even under the masterly government of William, disappointments had been felt by those who expected impossibilities from the Revolution; discontent now diffused itself very widely, the main cause being the increase of taxation which had been rendered necessary by the Continental war. The Tories and Jacobites, led by some of the ablest of the statesmen, and assisted by some of the most skilful and energetic of the political writers, dexterously used the combustible materials that were accumulating, and made the church also an active engine of mischief. The ministry saw their parliamentary majorities wasting away; they were personally treated at court with open contumely; and their ruin was completed when, still relying too boldly on their supposed strength, they impeached Sacheverell for publicly preaching in favour of Jacobitism and the divine right of kings. In August 1710 the Whig administration was ignominiously discarded.

The second period of the queen's reign began at this point. She was thenceforth governed by Mrs Masham; Mrs Masham was governed by Harley and St John, the chiefs of the new ministry; and these able and unscrupulous men exerted themselves to the utmost of their power in undoing all that had been done by their predecessors. The fruits of the war were immediately abandoned, and the allies of England shamefully betrayed, by the treaty of Utrecht. If open attacks were not made on the constitution, it was only because the Parliament could not be trusted in such a case, and because, also, the two ministerial leaders became jealous of each other, and formed separate intrigues. Harley, the Sinon of the time, corresponded both with St Germains and with Hanover; St John, more decidedly Jacobite, plotted with Mrs Masham and the queen to procure the crown for the Pretender, on the ostensible condition of his professing Protestantism. But these cabals oozed out sufficiently to alarm the honourable Tories, and to array them and the bishops against the ministry in Parliament. The time, likewise, during which the danger was growing, proved too short to allow it to become ripe. Harley and Mrs Masham came to an open quarrel one evening in Anne's presence; after they had squabbled for hours, the poor queen just retained strength enough to insist that the minister should resign on the spot; she then retired at two in the morning, and lay down on her deathbed. She was seized with apoplexy, and died on the 1st of August 1714. St John's schemes were not ready for execution; and, by the prompt activity of a few patriotic statesmen, the accession of George I. was immediately and peaceably secured. (W. S.)

(See Earl Stanhope's *History of England, comprising the Reign of Queen Anne until the Peace of Utrecht*, Lond. 1870.)

ANNEALING is the process of removing the brittleness peculiar to glass vessels and metal castings immediately after manufacture. Newly-blown glass is so fragile as to be altogether unfit for use, and the common occurrence of the breaking of a lamp-glass on lighting the lamp, or of a tumbler on pouring in hot water, shows the want of proper annealing.

The process consists generally in heating the vessels up to a red or white heat in a close oven, and allowing them to cool gradually over a space of several hours or even days. The brittleness of rapidly-cooled glass is exhibited by the philosophical toy known as *Rupert's drops* or *glass tears*, said to have been first brought over to England by Prince Rupert and exhibited at the court of Charles I. They are small tadpole-shaped pieces of glass, which have been formed by allowing fused glass to drop into water. A pretty hard blow may be given with impunity to the thick part or head of the glass tadpole; but the mere breaking off of the tail causes the whole to fly to pieces, or rather to dust, with a sharp explosion. An illustration of the same kind is given by what are known as *Bologna phials*. These are vessels of thickish glass about half the size of a common Florence oil-flask, with no apparent flaw or cause of weakness. Though they will stand the shaking of a small bullet within them, yet the shaking of a few particles of sharp sand hardly visible will cause the bottom to fly to pieces. It is the mere scratching of the skin that is fatal; and the explanation is easily found. The particles of the glass have a cohesive polarity which dictates a certain regularity in their arrangement, but which requires some time for its development. When the vessels are suddenly cooled, the surface molecules only can have had time to dispose themselves duly, while those within are kept by this properly formed skin in a highly constrained situation; and it is only so long as the surface film keeps sound that this constraint can be resisted. In the Rupert's drops it is plainly visible that the interior substance is cracked in every direction, and ready to fly to pieces.

In the process of annealing the glass is kept for some time in a state approaching fluidity, and admitting of a uniform molecular arrangement throughout. Of course the thicker the glass the more careful must be the annealing and the longer the process; very thin glass requires little or no annealing, because it is, so to speak, all skin; and glass thread requires no such treatment to make it possess the exquisite flexibility of silk.

The large sheets of plate glass, now used for shop windows require to be very carefully annealed before being ground and polished, otherwise they would be unable to stand the scratching of the surface. Imperfection in this respect is often revealed by the spreading in every direction of a crack once begun. These plates require as long as a fortnight to complete the annealing; and smaller articles from six to sixty hours, according to their thickness and weight

In the manufacture and working of the various metals, annealing is frequently employed to reduce the brittleness usually resulting from a rapid or important change of molecular structure, such as is produced by hammering, long-continued vibration, rolling, and sudden cooling. The coppersmith who hammers a flat sheet of copper into a vessel of any description he pleases, must leave off hammering at intervals, and anneal the piece of metal to prevent it going to pieces under his blows. The extreme degree of tenuity to which gold is reduced by heating, is attainable only by very frequent and careful heating and slow cooling at each stage of the processes of forging, rolling, and beating

Perhaps no better example can be given of the importance of annealing in metals th t have to be subjected to frequent concussion than the art of die-forging. The matrix, from which the die-punches are impressed, is the product of many months' labour, and the subject of tender care in its manufacture. Being a mass of steel of considerable dimensions, it is extremely liable to fracture after the operation of hardening, so much so that it will not bear even sudden changes of atmospheric temperature. This brittleness is removed by putting it in water, gradually raised to the boiling-point, and then allowed slowly to cool. The matrix is used, not so often for the stamping of medals and coins directly, as for the manufacture of die-punches, which shall be used to produce any required number of dies exactly like the original matrix. For this purpose a conical plug of fine soft steel is compressed by powerful machinery against the matrix, but in receiving the impression its texture is condensed and hardened, so that the annealing process has to be repeated after every few blows in the die-press, to prevent cracking of the surface Coins, whether gold, silver or copper, are usually impressed by a single blow, and in their case the blank metal is annealed before coining But in medals, where the design is in bolder relief, a number of blows,—sometimes as many as thirty, is required; and in this case it is necessary to anneal after every third blow

Wheels and axles of railway carriages, from the constant vibration to which they are subjected, become, in course of time, dangerously brittle; and they require to be re-worked and annealed anew to restore the requisite toughness to the material. So also in the processes of metal rolling and wire-drawing, frequent annealing is necessary to allow the cohesive force to produce the most stable arrangement of the particles. The soft metals, such as lead, tin, and zinc, are annealed by immersion in water, which is made to boil and then to cool slowly. Sudden changes of temperature have the effect, almost invariably, of rendering metals brittle. And, as sudden cooling is required to give to steel its peculiar and invaluable hardness, so unfortunately it renders it at the same time brittle as unannealed glass, from the unnatural strain which the inner substance of the metal possesses. Annealing must, therefore, be employed to reduce this molecular strain, and to give the steel a workable flexibility. This is done by raising it to a red heat within a close vessel, and then allowing it gradually to cool. Heating in an *open* fire is very injudicious, because the carbon which enters the steel as an element combines with the oxygen of the air to the detriment of the quality of the steel. Usually steel goods are heated in an iron oven with charcoal powder, or placed in the heart of hot cinders, so as to exclude all air and oxygen. Large castings, such as are used in the manufacture of cannon, are kept covered with hot cinders and allowed to cool down sometimes over a space of about three months.

In proportion as this brittleness and hardness are reduced by annealing, the flexibility is increased, which allows of the employment of steel for an infinite variety of purposes. A bath of oil, which boils at about 600° Fahr., is often used for the annealing of steel tools, when a temperature between the boiling-point of water and 500° or 600° Fahr. is required. Annealing is also employed to render cast-iron malleable or less brittle than it is naturally, so that a dozen of small articles—such as buckles and knife-blades—can be manufactured at less cost than a single article can be otherwise.

Annealing may be said to be the inverse process of *tempering*, which is the fixing of the molecular condition of steel by more or less sudden cooling from a particular temperature.

The real nature of the change which metals undergo by annealing is not thoroughly understood. Most of the malleable metals are susceptible of two distinct forms: one, called the crystalline form, which they assume by slow cooling; and the other, the fibrous, which is acquired by hammering or rolling. When this, however, is carried beyond a certain point, the metal becomes so hard that it is not capable of being bent far without breaking, and recourse must be had to annealing or slow cooling.

On the other hand, if the annealing be long continued the malleability diminishes, and the metal again has a crystalline fracture. Zinc by wire-drawing becomes very flexible, and possesses a degree of tenacity not inferior to that of copper; but, if it be kept in boiling water for a length of time, it will resume its original brittleness, and show a crystalline appearance when broken. Thus it appears that little can be said of the theory of the subject; little more, indeed, can be attempted than the enumeration and classification of the facts.

ANNECY, a town of France, in the deparment of Haute Savoie, situated at the foot of the lake of Annecy, 22 miles south of Geneva. The surrounding country presents many scenes of beauty, and the town itself is a pleasant residence, containing a cathedral, a bishop's palace, a church (in which the relics of St Francis de Sales are preserved), and an old castle, formerly the residence of the counts of Geneva. It is the seat of several important manufactures, the chief being linen and cotton goods, glass, cutlery, earthenware, and leather; linen bleaching is also carried on to a considerable extent, and in the neighbourhood there are some iron mines. There are traces of the Roman origin of the place; at all events Annecy le Vieux, a village a little to the N.E., existed in the time of the Romans. Annecy was once the capital of the counts of Geneva; from them it passed to the counts of Savoy, or, as they ultimately became, kings of Sardinia, by whom it was ceded to the French in 1860. Population, 11,581. The lake of Annecy is about 9 miles in length by 2 in breadth, and its surface is more than 1400 feet above the sea. It discharges its waters by means of a canal into the Fier, a tributary of the Rhone.

ANNELIDA

ANNELIDA, a class of the sub-kingdom Annulosa, the title being derived from Lamarck's term Annélides (*Annellus*, a little ring), given to Cuvier's red-blooded worms. The latter were included by Linnæus under his *Vermes*, along with intestinal worms, molluscs, zoophytes, and sponges. The labours of Pallas, Baster, Otho Fabricius, and especially O. F. Müller, enabled Gmelin, in the 13th edition of the *Systema Naturæ* of the great Swede, to make some improvements and many additions. Cuvier ranged the Annelida under his Articulata, giving them the chief position on account of their red blood; but they are now generally classified as a separate type below the latter. It would be out of place to enumerate all the advances that have occurred since Cuvier's time, but among those whose names stand prominently forward in this respect are Lamarck, De Blainville, Bosc, Audouin, Milne-Edwards, Dugès, Moquin-Tandon, and De Quatrefages in France; Van Beneden, Morren, and D'Udekem in Belgium; Gruithuisen, Oken, H. Rathke, Grube, Max Schultze, Hoffmeister, Hering, Kölliker, Schmarda, Keferstein, Ehlers, and Ratzel in Germany; Claparède in Switzerland; Malmgren, Metschnikoff, and Kowalevsky in Russia; Sars in Norway; Kinberg and Lovén in Sweden; Delle Chiaje in Italy; Stimpson, Leidy, A. Agassiz, and Verrill in North America; and Montagu, Dalyell, G. Johnston, J. R. Johnson, Williams, Huxley, Baird, and Ray Lankester in our own country.

FIG. 1.—*Nereis pelagica*. L. (*After Œrsted.*)

The Annelida may be described as bilaterally symmetrical animals, with flattened or cylindrical bodies, composed of numerous soft rings, or without such. The locomotive appendages (generally furnished with bristles) are not articulated. Nervous system consisting of a cephalic ganglion or pair of ganglia, connected on each side of the œsophagus with a chain of ganglia running along the ventral aspect. Mouth ventral; alimentary canal with an anus. Circulatory system with distinct vessels. The majority are small animals, but some reach the length of 6 feet and upwards, and are as thick as a finger.

In the present article the Annelida will be understood as comprehending the A. POLYCHÆTA, A. OLIGOCHÆTA, A. ONYCOPHORA, A. DISCOPHORA, and A. GEPHYREA, the first two being often placed together in the subclass Chætopoda.

I. In the first order, A. POLYCHÆTA, the body (fig. 1) is elongated, segmented, more or less cylindrical (certain tubicolous forms having two well-marked regions), and almost universally furnished with uniramous or biramous bristle-bearing feet (parapodia, Huxley). The first segment is modified, so as to form a head or snout, and has the eyes, tentacles, &c. The second or buccal segment bears the mouth and certain processes. The other segments have foot-tubercles, bearing bristles developed in special sacs (*e*, fig. 4), and various appendages, such as elytra, dorsal and ventral cirri, &c. The structure of the bristles (*e.g.* fig. 2) holds a prominent part in the discrimination of species and even genera, and the same may be said of the hooks of many of the Tubicola (fig. 3). A curious example of the Opheliidæ has no bristles, and *Tomopteris* has only one at the base of each tentacle. Posteriorly, the diminished body generally terminates in two elongated cirri in the free forms, while in the sedentary such processes are often absent. In *Polydora* (fig. 21) a curious funnel-like structure exists.

FIG. 2.—Bristle of *Pionosyllis Malmgreni*.

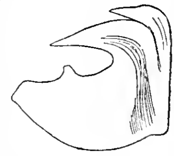


FIG. 3.—Hook of *Terebella*.

The body in the Polychæta (*e.g.* fig. 4) is invested by a

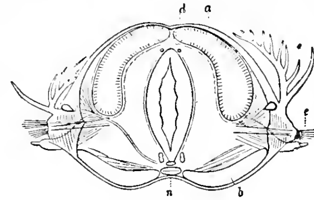

FIG. 4.—Transverse section of *Eunice*. (*After Ehlers*)

finely fibrous, cuticular, or chitinous layer (*d*), to which the iridescence in many forms is due. This is perforated at somewhat regular intervals by two series of pores, and cilia are generally present at certain points. In the sedentary annelids the cuticle is thinner, a feature probably in connection with their protective tubes. Beneath the cuticle is a cellulo-granular hypoderm, with tubular glands, bacilliparous and glandular follicles in certain cases, as well as the deposits of pigment. The muscular system is well developed, and the bands variously arranged in the body-wall. A well-marked circular layer is generally present externally, while in others it would seem to be represented only by oblique bands. The longitudinal bundles follow different plans, such as forming an almost continuous coat, or split up into various distinct ribands (*a* and *b*, fig. 4, the former representing one of the dorsal bands, the latter one of the ventral). Schneider thought that the arrangement of the muscular system might form the basis of a classification of this and allied groups; but for sound reasons it has not been adopted. There is no tendinous raphe at each segment, though fibres from the dissepiments pass through

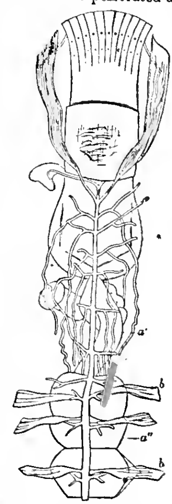

FIG. 5.—Ventral vascular system of *Nereis cultrifera*, Grube (*After Ehlers*). *a*, proboscis; *a'*, œsophagus; *a''*, intestine; *b*, dissepiments; *v*, ventral blood-vessel.

the longitudinal layer, in some cases even to the hypoderm. The muscular fibres have a hyaline connective tissue. In *Myxicola* and *Protula* the fibres of the longitudinal coat have a dendritic appearance in transverse section. Besides the foregoing, many have a powerful oblique band on each side, passing down to be inserted near the nerve-cord, or elsewhere; and the proboscis (*a*, fig. 5), bristles, branchiæ, alimentary canal, and other organs, have a series of special muscles. By the muscles of the body-wall the Polychæta execute all their movements in the water and on land, the feet-papillæ with their bristles playing quite a subordinate part. A few progress in addition by special organs, such as the tentacles of the Terebellæ.

The cutaneous and muscular tissues enclose a space termed the perivisceral cavity, which stretches from the anterior to the posterior extremity. This chamber is lined by a special membrane, which likewise envelops the alimentary canal, vessels, and other organs. It is generally divided into various transverse spaces by muscular dissepiments or screens (which permit communication), and occasionally there are longitudinal partitions. In this cavity the highly organised perivisceral corpuscles float in a coagulable lymph, which has no relation with sea-water. The lining membrane is ciliated in *Aphrodita*, *Glycera*, *Polycirrus*, *Tomopteris*, and *Terebella*; and it is curious that in these the blood-vessels proper are absent, with the exception of the first and last. Ray Lankester has found that hæmoglobin occurs in the perivisceral corpuscles of *Glycera* and *Capitella*. Professor Huxley, after M. de Quatrefages, is inclined to think the perivisceral fluid the true blood of the group, but this is doubtful.

The circulation of the blood is effected by a system of closed vessels with muscular walls (fig. 5) the funda-

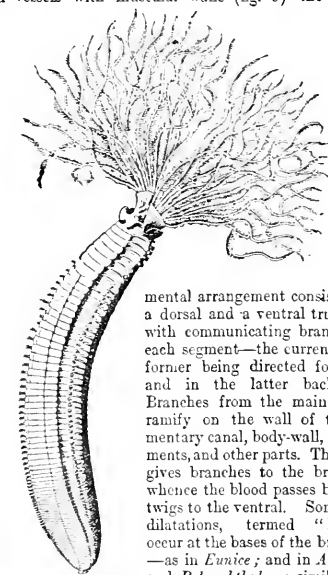

Fig 6.—*Dasychone infracta*, Kr (After Malmgren.)

mental arrangement consisting of a dorsal and a ventral trunk (*v*), with communicating branches in each segment—the current in the former being directed forwards, and in the latter backwards. Branches from the main trunks ramify on the wall of the alimentary canal, body-wall, dissepiments, and other parts. The dorsal gives branches to the branchiæ, whence the blood passes by other twigs to the ventral. Sometimes dilatations, termed "hearts," occur at the bases of the branchiæ —as in *Eunice*; and in *Arenicola* and *Polyophthalmus* similar dilatations exist in other parts. Various modifications of the system take place, such as the bifurcation of the dorsal vessel anteriorly or posteriorly, the presence of blood-sinuses or lacunæ round the intestine in certain sedentary forms, and great diversity in regard to capillary distribution. The blood is usually reddish in colour, and devoid of corpuscles—the latter, however, being present in *Syllida*, some of the Opheliidæ, Cirratulidæ, and in *Staurocephalus*. It is colourless in *Aphrodita*, greenish in *Stylaroides* and certain Sabellidæ. Finally, *Glycera* and *Polycirrus* are devoid of a true circulatory apparatus. This system is compared by Professor Huxley to the water-vascular system of the Echinoderms, Trematoda, and other groups; but, as formerly mentioned, this is doubtful. Hæmoglobin has been found by Ray Lankester in the blood of many of the Polychæta.

The Annelida composing this group generally possess a special branchial apparatus, and where this is absent (*e.g. Lumbriconereis*), the skin and ciliated digestive chamber seem to carry on the function. So characteristic are the branchiæ, that the term Dorsibranchs was aptly bestowed on one section (see fig. 4), and Cephalobranchs on the other (see fig. 6). The branchiæ have the form of simple filiform organs, or they are pinnate, bipinnate, pectinate (*e*, fig. 4), flabelliform, or arbuscular processes. To each the blood is carried by a branch of the dorsal vessel, which traverses the organ to its extremity, and, looping, carries the aerated fluid to the ventral vessel. Vascular loops pass between the two branches in the branchiæ, and only very thin cuticular tissues covered with cilia intervene between the water and the blood, so that due oxygenation occurs. In the Serpulidæ the branch from the dorsal vessel is continued directly into the twig going to the ventral, and from their point of union a single vessel traverses the branchia and sends processes into the pinnæ, the blood, moreover, in these presenting undulatory movements. A cartilaginous framework exists in the branchial processes of the latter group and the Sabellidæ (fig. 6). According to Fritz Müller the opercular plug in certain forms is developed by a gradual metamorphosis of the branchia.

The digestive system consists of a rounded alimentary canal, commencing at the second and terminating in an anus at the last or the penultimate segment. The mouth opens in the form of a simple slit or grooved dimple on the under surface of the second segment. In many the first region is a complex muscular and protrusible proboscis (fig. 5, *a*, pharynx and œsophagus of some, and the œsophagus of others), with papillæ, horny or dense calcareous teeth (fig. 7), with a narrow œsophageal region (*a'*) behind. Certain glandular organs in the œsophageal region of certain forms are termed salivary. The walls of the succeeding portion (*a''*) are often marked by numerous sacculations from constrictions at the dissepiments; and in some (*e.g.*, *Aphrodita*) large diverticula occur. The inner surface bears vibratile cilia, the walls are glandular, and there are also circular and longitudinal muscular fibres. The gland-cells contain numerous refracting granules, and the tissue is by some held to be homologous with the liver of the higher forms. Many modifications of this system exist: thus, for example, there is in *Syllis* a firm, smooth anterior region (*pharynx*), often armed, then a region provided with glands (*proventriculus* or gizzard), a stomach with a glandular sac on each side, and lastly the intestine. The food of the group consists of both animal and vegetable substances, and sandy mud is swallowed by others for the nutrient particles it contains.

Fig 7.—Tip of proboscis and horny teeth of *Polynoe impatiens*. (After Savigny.)

The nervous system has the form of a pair of cephalic ganglia, and a chain of ganglia placed along the ventral aspect of the body (*n*, fig. 4). The former lie over the œsophagus, and send branches to the eyes, tentacles, and other organs. A cord (buccal) joins them on each side to the ventral chain, and thus the œsophagus is encircled by a nervous collar. In each segment the ventral ganglia give out branches for the supply of the neighbouring organs and feet. The nerve-cells chiefly occur on the ventral surface and sides of the ganglia. In some (*e.g.*, *Terebella*), while the nerve cords are united in the anterior region, they are separate posteriorly. The eyes are much developed in *Alciope*, certain Syllidæ, and others; but, on the other hand, many are eyeless. Most of the eyes are mere masses of black pigment (sometimes capsulated) situated on the head, destitute of means of accommodation, with certain nerve-threads going to them. In *Alciope*, sclerotic, lens, retina, and other parts exist. In *Branchiomma* the eyes occupy the branchiæ, and in *Fabricia* the posterior end of the body. Otolithes are stated to be present in a few (*e.g. Arenicola*), but on these and other minute points further investigation is required. The sense of touch is extremely delicate in the group; on the surface at large, as well as in the tentacles and cirriform processes. *Evarne, Nephthys, Ophiodromus*, and others, exhibit remarkable irritability.

The Polychæta are for the most part diœcious, the sexual glands being variously developed on the inner surface of the body-wall or on the dissepiments, and developing in the forms of ruffs round the vascular axes. The products are detached into the perivisceral cavity. The ciliated and looped segmental organs of Dr Williams occur very generally, and may conduct outwards the sexual elements, but they have also been supposed to be excrementitious. In *Tomopteris* their ciliary current carries spermatozoa inwards, and the same may occur in other forms. The structure and deposition of the egg, and the changes in its development, agree with those in other classes. Certain Eunicidæ are ovo-viviparous. Occasionally the ova are borne on the back (*Polynoë*), or in a ventral pouch (*Autolytus cornutus*), until hatched, while in *Spirorbis* a modification of the operculum acts as an ovisac. The young escape as ciliated organisms with a long whip anteriorly; but, as development progresses, the cilia are confined to certain zones. A few immature forms, again, such as the young of *Nerine*, carry remarkable bristles, which are shed before the adult form is reached. Some have arranged the larval forms according to the zones of cilia and the temporary bristles. In the growth of the young animal the development of the new segments takes place between the first and last. In certain Nereidæ, *e.g. Nereis Dumerilii*, at least two sexual forms exist,—viz., a small adult which develops either ova or spermatozoa in the usual way (except that in the male the elements occur in two testicles placed in one segment), and, secondly, another which becomes transformed into a *Heteronereis* before the sexual elements are developed. Metschnikoff has further found another *Nereis* which is hermaphrodite. The phenomena of alternate generations is also observed in *Autolytus*, and fissiparity in *Filigrana*,—the latter, with *Spirorbis* and *Amphiglena*, being also hermaphrodite. The female *Autolytus* quite differs from the male, and has its body loaded with ova, which pass into a pouch in *A. cornutus*, Agass., and the products by-and-by get exit as free-swimming embryos. The male is wide in front, and has large tentacles, the sperm-sacs occupying the first five bristled segments. From the young of the foregoing is developed—so as to complete the series—the third kind, viz., the "parent-stock" of A. Agassiz, which differs from both the previous forms. No sexual elements occur in the parent-stock, but the males and females are produced from the body by transverse fission (fig. 8).

Regeneration of mutilated parts is common in the Polychæta, even to the reproduction of a head.

The tubes formed by many exhibit an amount of precision and skill not far removed from the powers of the most ingenious insects. In common with the Nemerteans, their skin exudes a tenacious secretion which coheres under water, and this alone forms the protective tube in some, while in others it is strengthened with mud (fig. 9), sand, gravel, shells, and stones. The secretion varies from the most delicate film in the Syllidæ, to the tough parchment-tubes of *Chætopterus*, or the rigid crow-quills of *Hyalinœcia* (fig. 10). The eyeless *Pectinaria belgica* (fig. 11), again, fashions a tube like a straight horn (fig. 12) of minute pebbles or large grains of sand, carefully selected and admirably fixed to each other by a whitish secretion. In placing the grains together in the wall there is no haphazard, but angle fits angle as in a skilfully built wall. Beautiful semi-transparent tubes are constructed by an allied species in the deep sea from the siliceous spicules of sponges. The remarkable arborescent or pectinate processes which ornament the free ends of the tubes of certain *Terebellæ* are also noteworthy. The calcareous tubes of the fixed Serpulidæ, or the free (*e.g. Ditrypa*), differ from those of the molluscs in the absence of organic connection between the animal and its protective sheath. Lastly, large coherent masses of coarse gravel and sand-tubes are formed on various beaches by *Sabellaria*.

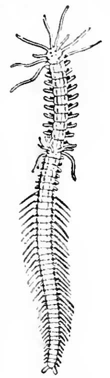

Fig. 8.—Parent-stock of *Autolytus cornutus*. (*After A. Agassiz.*)

Fig. 9.—*Clymene amphistoma*, Sav., with a fragment of tube on the right. (*After Savigny.*)

The annelids are subject to many parasitic inroads, as by *Gregarinæ*, *Opalinæ*, and *Nematoids*, internally; various vegetable growths, zoophytes, *Loxosomæ*, and the crustaceans *Selius, Selenium, Nereicola, Terebellicola, Sabelliphilus, Chonephilus*, and *Sabellacheres*, externally. Commensalism is likewise not uncommon; thus *Polynoë scolopendrina* haunts the tubes of *Terebella nebulosa*, and it also alternates with *Harmothoë marphysæ* in the tunnels of *Marphysa sanguinea*; *Acholoë astericola* frequents the ambulacral rows of *Astropecten*, *Malmgrenia castanea*, the peri-oral region of *Spatangus purpureus*, and *Nereilepas fucata* associates itself with the hermit-crab in Buccinum; while *Alciopina parasitica* lives in the interior of Pleurobrachia, and one of the Amphinomidæ in the respiratory cavity of Lepas.

The Polychæta are all marine, and distributed over the whole surface of the globe,—often at very great depths,—as early shown by General Sabine, and recently by the Norwegian dredgings, and those of the celebrated "Porcupine" and "Challenger" expeditions. Many species are common to the entire North Sea, and extend to the south as far as Gibraltar, while some northern forms enter the Mediterranean in considerable numbers. The British species are common to the North Sea, and many range to the shores of North America. The size of some of the

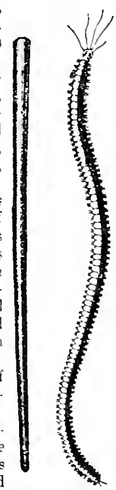

Fig. 10.—*Hyalinœcia tubicola*, O. F. Müller, and tube.

forms greatly increases in the Arctic Sea. The tropical waters abound with lustrous and splendidly tinted speci-

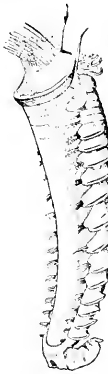

Fig. 11.—*Pectinaria belgica*, Pall. (*After Malmgren.*)

Fig. 12.—Tube of fig. 11, partially shaded.

mens, especially amongst the Amphinomidæ. The borers in shell, limestone, coral, and Melobesia, seem cosmopolitan, and the swimming *Tomopteris* is likewise widely distributed. The forms frequenting the bottom of the sea live in mud or sand, or lurk under stones, in chinks of rocks, shells, and seaweeds. Many specially affect mud or muddy sand, *e.g.*, the Lumbriconereidæ, Nephthydidræ, Glyceridæ, and the Terebellidæ; while some prefer hard or stony ground, *e.g.*, the Polynoidæ and Sigalionidæ. Between tide-marks they abound in fissures of rocks, under stones in pools, under tangle-roots, and in sand or sandy mud. Many live in captivity several years, but the duration of their existence generally is unknown.

Tubicolar Polychæta occur in various strata, from the Lower Silurian upwards, and *Serpulites* even appear in the

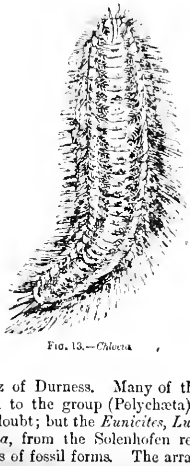

Fig. 13.—*Chloeia.*

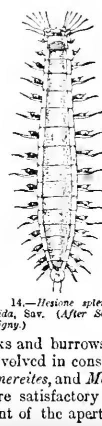

Fig. 14.—*Hesione splendida*, Sav. (*After Savigny.*)

quartz of Durness. Many of the tracks and burrows referred to the group (Polychæta) are involved in considerable doubt; but the *Eunicites*, *Lumbriconereites*, and *Meringosoma*, from the Solenhofen rocks, are satisfactory evidences of fossil forms. The arrangement of the apertures of *Arenicola didyma*, from the Longmynd, in pairs is peculiar.

In regard to beauty of form and colour, complex structure and wonderful habits, the Polychæta are not surpassed by any invertebrate class. The splendid bristles of the Aphroditidæ, constantly glistening with all the hues of a permanent rainbow, the brilliant tints of the Phyllodocidæ, Hesionidæ, and Nereidæ, and the gorgeous branchial plumes of the Terebellidæ, Sabellidæ, and Serpulidæ, can only be compared with the most beautiful types of butterflies and birds.

The class Annelida has been divided into the sections *Branchiata* and *Abranchiata*, the former comprehending the Polychæta, the latter the other groups; but this does not always hold good, since many Polychæta have no branchiæ. The latter, again, have been separated into the Dorsibranchs and Cephalobranchs, the former corresponding to the Maricola, Errantia, or Nereidæ of others, the latter to the Tubicola or Sedentaria. Grube's divisions, Rapacia and Limivora, are based on the nature of their food. In the present state of the department it will suffice to indicate the following families (chiefly after Malmgren) under which the Annelida Polychæta have been ranged, and to refer for further information to the *Annélides* of De Quatrefages, the *Familien* of Grube, the *Chætopoda* of Ehlers, the *Annélides Chétopodes* of Claparède, the *British Museum Catalogue* by Johnston and Baird, and the various works of Kinberg and Malmgren:—Euphrosynidæ, Amphinomidæ (fig. 13), Aphroditidæ, Polynoidæ, Acœtidæ, Sigalionidæ, Nephthydidæ, Phyllodocidæ, Hesionidæ (fig. 14), Alciopidæ, Tomopteridæ (provisionally), Syllidæ, Nereidæ (fig. 1), Staurocephalidæ, Lumbriconereidæ, Eunicidæ (fig. 4), Onuphididæ (fig. 10), Goniadidæ, Glyceridæ, Ariciidæ, Opheliidæ, Scalibregmidæ, Telethusidæ (fig. 20), Sphærodoridæ, Chloræmidæ, Sternaspidæ, Chætopteridæ, Spionidæ (fig. 21), Cirratulidæ, Capitellidæ, Maldanidæ (fig. 9), Ammocharidæ, Hermellidæ, Amphictenidæ (figs. 11 and 12), Ampharetidæ, Terebellidæ, Sabellidæ (fig. 16), Eriographidæ, and Serpulidæ (fig. 15).

Fig. 15.—*Spirorbis nautiloides*, Lamarck.

Fig. 16.—*Sabella vesiculosa*, Mont. (*After Montagu.*)

II. The A. Oligochæta are annelids without tentacles, cirri, or specialised branchial processes. Bristles, variously grouped, from two to eight and upwards in each transverse series. They are hermaphrodite, and the young undergo no metamorphosis.

The body is enveloped in a delicate cuticle resembling that of the Polychæta, and pierced by many pores. Underneath is a cellulo-granular hypoderm, with numerous glands. The setæ are simple, bifid, or hair-like. The muscular layers are an external circular, and an internal longitudinal, marked by the bristle sacs. The foregoing tissues enclose a perivisceral space, with the usual septa and the characteristic corpuscles in a coagulable lymph, which performs important functions in the economy.

The circulatory system consists essentially of a dorsal trunk situated over the digestive chamber, carrying the blood from behind forwards, and a ventral or sub-intestinal conveying the fluid in the opposite direction. The former is broken up into a plexus of vessels in the anterior segments, and generally gives off a large branch (perivisceral) on each side in the others. The perivisceerals in certain segments behind the anterior plexus are enlarged, and so evidently contractile as to have received the name of "hearts," and propel the blood into the ventral vessel. In the other segments the perivisceerals pass to the latter, either with or without division into branches—in the form of cutaneous plexuses, which are greatly developed in this group. Branches pass from the ventral to the intestinal wall, inosculating with others from the dorsal, and forming a rich capillary network. In the *Lumbrici* there is also a third longitudinal vessel underneath the nerve-cord, and it is in communication with both dorsal and ventral, especially by the cutaneous system. The blood is generally reddish, devoid of corpuscles, and coagulable. Respiration seems to be effected by the cutaneous and special plexuses, aided, probably, in some by the currents of water in the ciliated digestive canal.

The digestive system is in the form of a simple straight, more or less muscular tube, differentiated into œsophagus, crop, gizzard, and sacculated intestine in *Lumbricus*, and coated internally with the usual glandular elements (certain glands anteriorly being supposed to be salivary), and lined internally with cilia. In the same group a peculiar closed fold of the chamber constitutes the *typhlosolis* of authors. The anus is situated at the posterior end of the body. In the Limicolous group the structure is less complex—pharynx, œsophagus, and intestine only being present. The nervous system consists of a pair of cephalic ganglia, from each of which a trunk passes by the side of the œsophagus to join the ventral chain, which gives off branches in each segment to the surrounding parts. In *Lumbricus* another small gangliated chain lies over the commencement of the alimentary tract. The nervous system agrees in intimate structure with that of the Polychæta. Besides touch, and in some sight, the special senses are not much developed. Several have epidermal papillæ connected with cutaneous nerves, which probably aid tactile sensibility.

The Oligochæta are hermaphrodite, the sexual elements being developed in certain anterior segments in the form of testicles, deferent canals, receptacles, copulatory papillæ in some males, and ovaries and accessories in the female. In each segment, with a few exceptions (while there are two in each in *Lumbricus*), the segmental organs occur. Claparède thought that in the Limicola the latter are absent from the segments bearing the oviducts and seminal receptacles, but present in those having male organs; while in *Lumbricus* they are present in all the segments except the four last. In some, special glands exist for secreting the egg-capsules. A cincture or clitellum occurs in certain segments anteriorly (in *Lumbricus* from the eighteenth to the twenty-ninth or thirtieth, and in the others from the tenth to the fifteenth segment). The ova are deposited in chitinous capsules (containing one or more), and the young issue therefrom in a tolerably complete condition. Besides the ordinary development by ova, it has long been known that *Nais* and *Chætogaster* exhibit fissiparous reproduction. In *Nais*, after a certain degree of growth has been reached, budding takes place, so that several tolerably complete young forms may be found attached to the adult. The process goes on until the *Nais* has been reduced to twelve or fourteen rings; then a pause occurs, and the animal increases in length to forty or fifty rings, when a new cycle commences by division in the middle of the body. *Chætogaster* shows similar features, the budding taking place between the third and fourth segments in the androgynous form—many zoids or buds being attached in line; but while the second in position is one of the newest, the second in age is near the middle of the series.

Reproduction of lost parts readily takes place in this group. Parasites, such as *Gregarinæ*, *Opalinæ*, Nematoids, and larval cestodes, are met with internally, and *Vorticellæ* are common externally. Commensalism is seen in *Chætogaster*, which lives on the pond-snails (*Limnæus* and *Planorbis*), and *Stylaria* is stated also to be ectoparasitic.

They are distributed over the land and fresh waters (in sand and mud) of the whole world: very few are marine.

Two of the most important classifications are those of D'Udekem and Claparède. The former arranges the suborders according to the gemmiparous, or non-gemmiparous condition of the constituents. The latter group live in earth or mud, are unable to swim or follow their prey, and have always their organs of generation. The former are elegant little worms, living in stagnant or running water, able to swim, and their generative organs are developed only at certain periods. Claparède divides them into two families, viz., the *O. Terricola* (including the earthworm and its allies), and the *O. Limicola*, an arrangement much resembling Grube's *Lumbricina* and *Naidea*.

III. The A. Onychophora are represented by a single aberrant family, *Peripatus*. They are hermaphrodite forms (with claws instead of bristles) approaching the Arthropods, and inhabiting land and moist places in Chili, the West Indies, and other parts. The ventral nerve-cords remain separate.

IV. The A. Discophora (leeches) are ringed forms (fig 17), without lateral appendages (except in *Branchellion*), but possessing an anterior and posterior sucker. There is no specialised respiratory system. They are generally hermaphrodite, and often ectoparasitic.

Fig. 17.—*Hirudo medicinalis*, L.

Externally there is a delicate porous cuticle; beneath lies a thick glandular cutis, which pours out an abundant secretion of mucus, as in the Nemerteans. The muscular system consists of an external circular coat of considerable strength, from which various vertical or decussating bands pass at intervals, powerful longitudinal bundles being held in the intermediate spaces, especially laterally. There are also special muscles connected with the pharynx and other parts. Each end of the body is generally formed into a flattened muscular sucker, consisting apparently of several amalgamated segments. By aid of the latter organs they move from point to point, and they can also progress rapidly by swimming like the Nemerteans. The perivisceral space is quite absent. The circulatory system shows a main dorsal, a ventral, and two lateral trunks, all communicating by branches in each ring. In *Branchiobdella* the blood is corpusculated. The blood is probably aerated on the cutaneous, and perhaps, in some cases, on the digestive surface. The digestive system consists of a mouth opening into the anterior sucker, a muscular pharynx, œsophagus, a large stomach with various cæcal diverticula, and an anus which opens in front of the posterior sucker, though sometimes into it. In some (*e.g.* the common leech), the mouth is furnished with three horny serrated teeth. The nervous system is composed of two cephalic ganglia, which supply branches to the eyes when present, and the usual gangliated ventral cord—giving off branches to the surrounding parts. The gullet passes through the connecting trunks as in the former groups. The last ganglion in the ventral cord of *Clepsine* is larger than the others; and, as in the Polychæta, the ganglia do not always correspond in number with the rings. Other nerves occur in several, *e.g.*, the leech, which has a trunk running along the dorsal surface of the digestive canal. Eye-specks are present in some, and touch is generally much developed. The cupuliform organs in the cutaneous tissues of the head and anterior region in certain leeches are supposed to be connected with the latter sense.

The Discophora are hermaphrodite (with the exception of the *Malacobdellidæ* and *Histriobdellidæ*), with the male organs ranged along the ventral surface in the form of a series of testes, which are connected with a common vas deferens leading into a vesicula seminalis on each side. The latter conveys the fluid into the intromittent organ, and its secretion agglutinates the spermatozoa into a seminal rope or spermatophore. The female organs consist of two ovaries leading to a common duct, opening into the vagina, which receives the spermatophore. The segmental organs are present, but not in direct communication with the reproductive structures, nor do they carry the products to the exterior, since they are often cæcal. The foregoing diverges from the arrangement in the other Annelida, since the generative products are not extruded into a perivisceral cavity, but pass outwards by a particular apparatus. The ova are deposited in capsules formed by special secretions, those of the leech being called cocoons. No metamorphosis occurs in the development of the young, which by-and-by, in some cases, attach themselves in crowds to the abdominal surface of the parent.

The Discophora do not possess much power of regenerating lost parts. They are distributed everywhere, chiefly

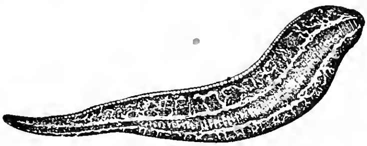

Fig. 18.—*Hirudo medicinalis*, L., var. *officinalis*. The green leech.

in fresh water and moist places; some are marine. A few attain a large size, *e.g.*, a species from Valdivia is described as being two and a half feet long. Many are ectoparasitic, living on fishes, crabs, and even in jelly-fishes (Bolinidæ). In swampy ground in tropical countries certain leeches are often troublesome to travellers. Fossil leeches have been found in the lithographic stones of Germany They have been grouped into five families, viz., Malacobdellidæ, Histriobdellidæ, Acanthobdellidæ, Branchiobdellidæ, and Rhynchobdellidæ—the latter including the medicinal leech of Europe, the green leech (fig. 18), the *Bdella nilotica* of Savigny (fig. 19), the horse-leech, skate-leech, pond-leech, which is devoid of an anterior sucker, and other well-known forms.

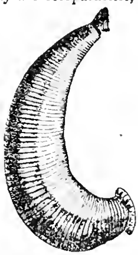

Fig. 19.—*Bdella nilotica*, Sav. (*After Savigny.*)

V. The A. Gephyrea seem to approach the Echinoderms through the Holothuroidea. The body is more or less cylindrical, and, though corrugated, is not definitely segmented. There is generally a protrusible proboscis, having the mouth at the end or at its base; and the anus is terminal or dorsal.

The cuticle is chitinous, has numerous processes of similar composition, longitudinal and transverse rugæ, and many pores. Beneath is a hypoderm containing certain glandular organs or sacs, and, in some, bodies like tricho-cysts. Bristles occur in *Echiurus* and *Bonellia*. The muscular system consists of external circular and internal longitudinal fibres, and special groups of retractor and other muscles of the proboscis. In some the longitudinal layer is arranged in separate bands, stretching from one end of the body to the other. The circulatory system shows a dorsal and ventral vessel, both in the Sipunculidæ communicating with a circular vessel (ciliated internally) surrounding the œsophagus, and sending prolongations into the ciliated tentacles. The latter contains a corpusculated fluid. Certain ciliated infundibuliform organs also occur on the intestinal mesentery of *Sipunculus*, and are thought to be connected with the so-called water-vascular system. In *Echiurus* there is a more distinct circulation, consisting, according to De Quatrefages, of three longitudinal trunks—a dorsal, ventral, and intestinal. The perivisceral cavity is large, with rudimentary dissepiments in some, and contains a corpusculated fluid, which in the living animal shows very lively currents—most marked posteriorly, and generally in a longitudinal direction. In *Bonellia* the respiratory structures open into the latter chamber. Two kinds of excretory organs occur—in some opening into the rectum, and in others into the alimentary cavity anteriorly. The protrusible proboscis is often armed with chitinous processes. The mouth opens at the base of the proboscis in the Echiuridæ, but at its tip in the Sipunculidæ, the latter also having short ciliated tentacles surrounding the aperture. It is followed by a pharynx and much-convoluted alimentary canal lined with cilia. The anus is either terminal, or situated dorsally at a point near the anterior third of the body. The walls of the alimentary canal are glandular, and there are also muscular fibres. The nervous system consists of a ventral cord giving off various branches, but showing no distinct ganglionic enlargements, nor indication of a fusion of two cords. There is an œsophageal collar, but the cephalic ganglia do not seem to be always distinct. There are no organs of the special senses except those of touch, which is fairly developed, and in a few eye-specks, especially in young forms.

The A. Gephyrea are diœcious, and have structures homologous with the segmental organs of the other groups, in the form of a series of tubes or cæca. In the *Sipunculi*, according to Keferstein and Ehlers, there are two testicles, and the ova are developed in ovaries attached to the wall of the body, but they vary in situation in other families. The products fall into the perivisceral cavity. In some the young undergo certain metamorphoses (*Actinotrocha*-form), but in others the larval condition differs from the adult chiefly in the possession of ciliated zones.

The Gephyrea are widely distributed on the surface of the globe, generally in muddy regions, and some are common in empty univalves. They are all marine. They have been grouped in three families: (1.) *Echiuridæ*, containing forms with bristles, such as the common spoon-worm (Echiurus vulgaris) and *Bonellia;* (2.) *Sipunculidæ*, with a dorsal anus, *e.g.*, *Phascolosoma Bernhardi* of the univalve shells; (3.) *Priapulidæ*, with a terminal anus, *e.g.*, *Priapulus caudatus*. *Sternaspis* has lately been removed to the Polychæta, and *Phoronis* has been included in the group as a tubicolar Gephyrean.

The Chætognatha and the higher Turbellaria approach the Annelida proper very closely, though from different points of view, and may be regarded as intermediate between them and the Nematodes, Tematodes, and Cestodes. The Nemerteans (the highest group of the Turbellaria) especially come near the Annelida, notwithstanding the condition of the nervous system. They have cilia externally, and a cutis which secretes similar hyaline tubes to those of many Annelida. The muscular system is greatly developed, and in definite layers, and many swim as freely as the most active leeches. The digestive system intimately agrees, having cilia on the inner surface of the canal, a muscular œsophageal region, and a sacculated intestine, while the glandular and other elements in the wall are very similar; it differs in not passing through a buccal nervous collar, although it lies beneath the nervous system in this region. The circulatory apparatus is fairly developed, and in some corpusculated. The special plexus, in certain forms, in the œsophageal part of the digestive tract points out not only the true function of the vessels (which have been considered a water-vascular system without reference to the cephalic sacs and their ciliated vessels in the Enopla), but shows a close analogy with the anterior plexuses of many Annelida proper and *Balanoglossus*, and even foreshadows the branchial system of certain vertebrates, as seen, for instance, in the young *Petromyzon*. The appending of the branchial system to the anterior end of the digestive is characteristic. Though it is quite inaccurate to say that the Nemerteans have a corpusculated fluid in the general cavity of their bodies, yet a highly organised corpusculated fluid exists in their muscular proboscidian chamber, and evidently performs important functions in their economy Moreover, the remarkable proboscis and its sheath pass through a ring of nervous tissue consisting of the superior and inferior commissures and their connections with the ganglia. The cephalic ganglia are large, and lie over the digestive system, but the nerve-cords are separated throughout. The Nemerteans are chiefly diœcious, and the products of their sexual organs, which are developed in the form of a series of sacs on each side between the muscular wall of the body and the digestive canal, find exit by lateral pores, the contents of the male organs being often vented in clouds, as in *Hermella*. The young sometimes undergo a metamorphosis, *e.g.*, the *Pylidium*-development of certain Anopla. To this the *Tornaria*-condition of *Balanoglossus* and the *Actinotrocha*-state of certain Gephyrea show similar features; and the three forms lead by separate channels to the Annelids proper There is little analogy with the Tunicates, but the similarity of the development of certain Echinoderms to the three forms just mentioned is eminently suggestive.

Finally the Annelida as a whole show certain general features which may be grouped under three heads—(1.) The uses of the class to man; (2.) The property of phosphoresence; and (3.) The power of boring into hard substances.

The Annelida are not devoid of value in an economical sense. All round the British and many other coasts the lobworm (*Arenicola marina*, fig. 20) is used as bait; and here and there *Nephthys cœca* and *Nereilepas fucata*. In the Channel and Channel Islands two of the most plentiful of the Nereidæ (*Nereis cultrifera* and *N. diversicolor*) are extensively employed in fishing.

Fig 20. — *Arenicola marina*, L.

They are constantly sought for between tide-marks with a pointed instrument resembling a spear, and kept in vessels amongst sand and seaweeds. One of the most esteemed baits in ordinary and in conger fishing in the same regions is the large *Marphysa sanguinea*. The anterior segments of the living annelid only are preserved, since the posterior region is apt to decay and cause the death of the whole. The natives of the Fiji group much relish a form allied to our *Lysidice ninetta*, and they predict its annual appearance in their seas by observing the phases of the moon. It is called Palolo by the Samoans and Tonguese, and Mbalolo by the Fijians. Occurring in vast numbers, formal presents of the esteemed food are sent by the fortunate chiefs considerable distances to those whose dominions are not visited by the annelid. If the latter has similar habits to the British *Lysidice*, it probably leaves its retreats in the coral-reefs and rocks for the purposes of reproduction. The extensive use of the *Lumbrici* in fresh-water fishing, and that of the leech in medicine, need only be alluded to—the latter forming a considerable item in British importations. *Echiurus* is employed as bait by the Belgian fishermen, and Pallas records that the natives of the same coast formerly considered the muscular proboscis of the sea-mouse good food. Lastly, a *Sipunculus* is eaten by the Chinese. An examination, again, of the stomachs of our most valuable fishes shows the important part played by the Annelida in their food-supply; and the large number of species of fish which can be speedily captured on a rich coast with bait of *Nereis cultrifera* is ample corroboration. The stomachs of cod and haddock, for instance, are often quite filled with sea-mice with Polynoidæ, Terebellidæ, *Alitta virens*, *Owenia*, *Trophonia*, *Phascolosoma*; and in fresh water those of trout with *Lumbrici*.

The property of phosphorescence occurs in the families Polynoidæ, Syllidæ, Chætopteridæ, and in *Polycirrus* and *Lumbricus*. In the first-mentioned, light greenish and somewhat steady scintillations are given off at the attachment of each scale, and the separate organ gleams with pulsations of light at the ruptured surface. It was probably the latter appearance which caused M. de Quatrefages to state that it was emitted in muscular contraction. The synchronous emissions of light by the Italian fire-flies is interesting in this respect. In the Syllidæ the light comes from the under surface of each foot; in *Chætopterus* the most vivid luminosity is on the dorsum of the tenth segment; and *Polycirrus* is so phosphorescent, that the slightest tremor in the water causes vivid pale bluish fire to gleam along every tentacle. The exact physiology of the luminosity is still open to investigation, though P. Panceri of Naples connects it with certain fatty granules. The luminous emissions have no connection with light or darkness, with the capture of prey, or the alluring of their enemies, nor with the illumination of the depths of the sea.

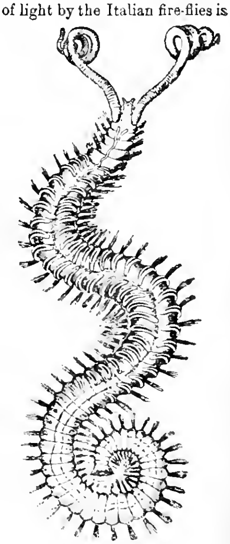

Fig 21.—*Polydora ciliata*, Johnst.

Boring and burrowing in sand, mud, and earth are very general in the Annelida. *Glycera* and *Nephthys*, for instance, disappear with great rapidity amongst sand by boring with their proboscides, the former passing its elongated organ through a considerable space in a single thrust. *Eteone* and *Ammotrypane* carry their bodies swiftly through moist sand and gravel. Others penetrate muddy clay and the debris in fissures of rocks. The labours of the earthworm in passing through the soil only require indication; and the Gephyrea and some leeches show the same habits in clay and mud. Certain Polychæta and Gephyrea have also the power, in common with cirripedes, molluscs, Bryozoa, and sponges, of perforating rocks, stones, shells, and other solid media. The most conspicuous forms are *Polydora* (fig. 21), *Dodecaceria*, *Sabella saxicava*, and *Phascolosoma Johnstoni*. Though such annelids are very abundant in corals, limestone, chalk, and shells, yet their occurrence in large numbers in aluminous shale and sandstone shows that their perforations are not necessarily due to an acid. The influence of the boring annelids in disintegrating the foregoing substances is considerable. (W. C. M.)

ANNESLEY, ARTHUR. See ANGLESEA, Earl of.

ANNI, or ANI, the ancient *Abnicum*, a ruined city of Turkey in Asia, in Armenia, situated about 25 miles E.S.E. of Kars, in a rocky ravine, past which the Arpa-Chai, a tributary of the Aras or Araxes, flows. The private houses of Anni are now little more than heaps of loose stones, but in the ruins of the public buildings there is still ample evidence of the former size and greatness of the city. Several churches, mosques, and a building which was probably the palace, as well as the massive walls of the city, are the most perfect and conspicuous remains at Anni, and exhibit many points of great architectural beauty. Anni was the capital of the Pakradian or Bagratian dynasty of Armenian kings, and under their rule reached the height of its greatness. Alp Arslan captured it in 1064, and handed it over to a tribe of Kurds, from whom it was taken by the Georgians. In 1319 an earthquake completed the misfortunes of the city, reducing it to the state in which it now exists.

ANNO BOM, or ANNABONA, a small island off the west coast of Africa, situated in lat. 1° 24′ S. and long. 5° 35′ E., 190 miles west of Cape Lopez. Its length is about four miles, its breadth two; and, rising in some parts to a height of nearly 3000 feet above the sea, it presents a succession of beautiful valleys and steep mountains, that are covered with rich woods and luxuriant vegetation. The inhabitants, who probably amount to about 3000, are negroes, very ignorant, but professing a belief in the Roman Catholic faith. Their chief town, a village on the north-east of the island, is merely a collection of rude huts, with an equally barbarous chapel. The roadstead is tolerably safe, and passing vessels frequently take advantage of it in order to obtain water and fresh provisions, of which Anno Bom contains an abundant supply. The island was discovered by the Portuguese on the 1st of January 1473, from which circumstance it received its name, "Dia de Anno Bom," being the Portuguese term for New-Year's day. It is claimed both by Spain and Portugal, but neither of these nations exercises any authority in the island, which is governed by a native, or rather it is said by a body of five natives, each of whom holds the office of governor in turn, during the period that elapses till ten ships touch at the island.

ANNONAY, a town of France, in the department of Ardèche, irregularly but picturesquely built on several small hills at the confluence of the rivers Canse and Deôme, 37 miles south of Lyons. It contains few buildings that are worthy of notice, although an obelisk in honour of the celebrated brothers Montgolfier, inventors of the balloon, who were natives of the place, and the Gothic church of Trachi, built in the 14th century, deserve to be mentioned. The manufactures of Annonay are among the most important in the department, the chief being those of paper, long considered to be the best in France, and glove leather, while cotton, woollen, and silk goods are also produced. Population, 18,445.

ANNUITIES

BY an annuity is meant a periodical payment, made annually, or at more frequent intervals, either for a fixed term of years, or during the continuance of a given life, or a combination of lives, as will be more fully explained further on. In technical language an annuity is said to be payable for an assigned *status*, this being a general word chosen in preference to such words as "time," "term," or "period," because it may include more readily either a term of years certain, or a life or combination of lives. The magnitude of the annuity is the sum to be paid (and received) in the course of each year. Thus, if £100 is to be received each year by a person, he is said to have "an annuity of £100." If the payments are made half-yearly, it is sometimes said that he has "a half-yearly annuity of £100;" but to avoid ambiguity, it is more commonly said he has an annuity of £100, payable by half-yearly instalments. The former expression, if clearly understood, is preferable on account of its brevity. So we may have quarterly, monthly, weekly, daily annuities, when the annuity is payable by quarterly, monthly, weekly, or daily instalments. An annuity is considered as accruing during each instant of the status for which it is enjoyed, although it is only payable at fixed intervals. If the enjoyment of an annuity is postponed until after the lapse of a certain number of years, the annuity is said to be deferred. When an annuity is deferred for any number of years, say n, it is said, indifferently, to commence, or to be entered upon, after n years, or to run from the end of n years; and if it is payable yearly, the first payment will be made at the end of $(n+1)$ years; if half-yearly, the first half-yearly payment will be made at the end of $(n+\frac{1}{2})$ years; if quarterly, the first quarterly payment will be made at the end of $(n+\frac{1}{4})$ years; and so on. If an annuity, instead of being payable at the end of each year, half-year, &c., is payable in advance, it is called an annuity-due.

If an annuity is payable for a term of years independent of any contingency, it is called an annuity certain; if it is to continue for ever, it is called a perpetuity; and if in the latter case it is not to commence until after a term of years, it is called a deferred perpetuity. An annuity depending on the continuance of an assigned life or lives, is sometimes called a life annuity; but more commonly the simple term "annuity" is understood to mean a life annuity, unless the contrary is stated. A life annuity, to cease in any event after a certain term of years, is called a temporary annuity. The holder of an annuity is called an annuitant, and the person on whose life the annuity depends is called the nominee.

If not otherwise stated, it is always understood that an annuity is payable yearly, and that the annual payment (or rent, as it is sometimes called) is £1. Of late years, however, it has become customary to consider the annual payment to be, not £1, but simply 1, the reader supplying whatever monetary unit he pleases, whether pound, dollar, franc, thaler, &c. It is much to be desired that this course should be followed in any tables that may be published in future.

The annuity, it will be observed, is the totality of the payments to be made (and received), and is so understood by all writers on the subject; but some have also used the word to denote an individual payment (or rent), speaking, for instance, of the first or second year's annuity,—a practice which is calculated to introduce confusion, and should therefore be carefully avoided.

The theory of annuities certain is a simple application of algebra to the fundamental idea of compound interest. According to this idea, any sum of money invested, or put out at interest, is increased at the end of a year by the addition to it of interest at a certain rate; and at the end of a second year, the interest of the first year, as well as the original sum, is increased in the same proportion, and so on to the end of the last year,—the interest being, in technical language, converted into principal yearly. Thus, if the rate of interest is 5 per cent., £1 improved at interest will amount at the end of a year to £1·05, or, as we shall in future say, in conformity with a previous remark, 1 will at the end of a year amount to 1·05. At the end of a second year this will be increased in the same ratio, and then amount to $(1·05)^2$. In the same way, at the end of a third year, it will amount to $(1·05)^3$, and so on.

Let i denote the interest on 1 for a year; then at the end of a year the amount of 1 will be $1+i$. Reasoning as above, at the end of two years the amount will be $(1+i)^2$, at the end of three years $(1+i)^3$, and so on. In general, at the end of n years the amount will be $(1+i)^n$; or this is the amount of 1 at compound interest in n years. The present value of a sum, say 1, payable at the end of n years, is such a sum as, being improved at compound interest for n years, will exactly amount to 1. We have seen that 1 will in n years amount to $(1+i)^n$, and by proportion we easily see that the sum which in n years will amount to 1, must be $\frac{1}{(1+i)^n}$, or $(1+i)^{-n}$ It is usual to put v for $\frac{1}{1+i}$, so that v is the value of 1 to be received at the end of a year, and v^n the value of 1 to be received at the end of n years.

Since 1 placed out at interest produces i each year, we see that a perpetuity of i is equal in value to 1; hence, by proportion, a perpetuity of 1 is equal in value to $\frac{1}{i}$. At 5 per cent., $i=·05$, and $\frac{1}{i}=20$; or a perpetuity is worth 20 years' purchase: at 4 per cent., it is worth 25 years' purchase, $\left(\frac{1}{·04}=25\right)$: at 3 per cent., it is worth $33\frac{1}{3}$ years' purchase, $\left(\frac{1}{·03}=33\frac{1}{3}\right)$.

Instances of perpetuities are the dividends upon the public stocks in England, France, and some other countries. Thus, although it is usual to speak of £100 consols, this £100 is a mere conception or ideal sum; and the reality is the £3 a year which the Government pays by half-yearly instalments. The practice of the French in this, as in many other matters, is more logical. In speaking of their public funds, they do not mention the ideal capital sum, but speak of the annuity or annual payment that is received by the public creditor. Other instances of perpetuities are the incomes derived from the debenture stocks now issued so largely by various railway companies, also the feu-duties commonly payable on house property in Scotland. The number of years' purchase which the perpetual annuities granted by a government or a railway company realise in the open market, forms a very simple test of the credit of the various governments or railways. Thus at the present time (May 1874) the British perpetual annuity of £3, derived from the 3 per cent. consols, is worth £93, or 31 years' purchase; and a purchaser thus obtains 3·226 per cent. interest on his investment. Other examples are given in the subjoined tables, the figures in which are deduced from the Stock Exchange quotations of the irredeemable stocks issued by the various governments:—

Name.	No. of Years'. Purchase.	Interest per cent. yielded to a Purchaser.
British,	31·00	3·23
Dutch,	23·69	4 22
Swedish,	21·20	4·72
Russian,	20·40	4 90
French,	19·67	5·08
Brazilian,	20·00	5·00
Portuguese,	15·42	6·48
Argentine,	13·50	7·41
Austrian,	13·40	7·46
Italian,	13·00	7·69
Turkish,	9·50	10·53
Spanish,	6·67	15·00
Venezuelan,	3·50	28·57

The following are a few other examples of perpetuities:—

Name.	No. of Years' Purchase.	Interest per cent yielded to a Purchaser
Metropolitan Board of Works Stock,	27·50	3·64
London and N.W. Railway Debenture Stock,	25·75	3·88
North British Railway Debenture Stock,	23·50	4·26
Edinburgh Water Annuities,	22·58	4·43

We may mention in passing that the more usual practice of foreign governments when borrowing is not to grant the lender a perpetual annuity, but to issue to him bonds of say £100 each, bearing an agreed rate of interest, these bonds being usually issued at a discount, and redeemed at par by annual drawings during a specified term of years.

We have seen that the present value of any sum payable at the end of n years is found by multiplying it by $(1+i)^{-n}$; hence the value of a perpetuity of 1 deferred n years is $\frac{(1+i)^{-n}}{i}$. Now an annuity for n years is clearly the difference between the value of a perpetuity to commence at once and a perpetuity deferred n years; its value is therefore $\frac{1}{i}-\frac{(1+i)^{-n}}{i}=\frac{1-(1+i)^{-n}}{i}$; or putting a for the value of the annuity, we have—

$$a=\frac{1-(1+i)^{-n}}{i}$$

By means of this equation, having any two of the three quantities, a, i, n, we can determine the third either exactly or approximately. Thus for n we have—

$$n=-\frac{\log\ (1-ia)}{\log\ (1+i)}.$$

There is no means of determining the value of i exactly, but it may be found to any degree of accuracy required by methods of approximation which our limits will not allow us to describe.[1]

[1] A similar difficulty meets us in many other cases, as, for instance, when we wish to determine the rate of interest, having given the amount of an annuity for a given term, or the value of an annuity or perpetuity deferred for a certain number of years. The reader who wishes to pursue this subject is referred to Francis Baily's *Doctrine of Interest and Annuities*, 1808, in the appendix to which the formulas of previous authors are examined, and new ones, which are at once simpler and more correct, are demonstrated. Particular cases of the problem are considered in Turnbull's *Tables of Compound Interest and Annuities*, p. 132, and in various papers in the *Assurance Magazine*, among which may be specified De Morgan's paper "On the Determination of the Rate of Interest of an Annuity," vol. viii. p. 61, and a letter by J. M'Lauchlan in the eighteenth volume. The analogous

If the annuity for n years is not to be enjoyed at once, but only after the lapse of t years, its value will be reduced in the proportion of 1 to the value of 1 payable in t years, or $1 : (1+i)^{-t}$; and the value of the deferred annuity to continue for n years is therefore—

$$\frac{(1+i)^{-t}}{i}\{1-(1+i)^{-n}\}.$$

It remains to find the amount at compound interest at the end of n years of an annuity payable for that term. The amount of 1 in n years being $(1+i)^n$, its increase in that time is $(1+i)^n - 1$; but this increase arises entirely from the simple interest, i, of 1 being laid up at the end of each year and improved at compound interest during the remainder of the term. Hence it follows that the amount at compound interest of an annuity of i in n years must be $(1+i)^n - 1$; and by proportion the amount of an annuity of 1 similarly improved will be $\frac{(1+i)^n-1}{i}$

One of the principal applications of the theory of annuities certain is the valuation of leasehold property; another is the calculation of the terms of advances in consideration of an annuity certain for a term of years. At present a large sum of money is annually borrowed by corporations and other public bodies upon the security of local rates in the United Kingdom. It is sometimes arranged in these transactions that a fixed portion of the loan shall be paid off every year; but it is more commonly the case that, in consideration of a present advance, an annuity is granted for a term of years, usually 25 or 30, but in some instances extending to 50. Landed proprietors also, who possess only a life interest in their property, have been authorised by various Acts of Parliament to borrow money for the purpose of improving their estates, and can grant a rent-charge upon the fee-simple for a term not exceeding 30 years. These are very favourite investments with the life insurance companies of the country, as they are thus enabled to obtain a somewhat higher interest—from $4\frac{1}{4}$ to $4\frac{3}{4}$ per cent.—than they could obtain upon ordinary mortgages with equally good security; the reason for this, of course, being that these loans are not so suitable as others for private lenders. In this case, as in all others, the price is determined by the laws of supply and demand; and the number of lenders being less than in the case of ordinary mortgages, the terms paid by the borrowers are higher. When a loan is arranged in this way, it is desirable for various purposes, and in particular for the ascertainment of the proper amount of income-tax, to consider each year's payment as consisting partly of interest on the outstanding balance of the loan and partly as an instalment of the principal. The problem of determining the separate amounts of these has been considered by Turnbull, *Tables*, p. 128; and by Gray, *Ass. Mag.*, xi. 172.

In making calculations for these and similar purposes, it is but seldom necessary to use the formulas given above. The computer usually has recourse to one of the tables which have been published, containing values and amounts calculated for various rates of interest. An extensive set of tables of this kind was published in 1726 by John Smart; and many subsequent writers, as Dr Price, Baily, Milne, Davies, D. Jones, J. Jones, have reprinted or abridged portions of these tables. They show the amount and the present value both of a payment and of an annuity of £1 for every term of years not exceeding 100, at the several rates of interest, 2, $2\frac{1}{2}$, 3, $3\frac{1}{2}$, 4, 5, 6, 7, 8, 9, 10 per cent.; the five most important tables giving—

(1.) The amount of £1 in any number of years, n; or $(1+i)^n$.

(2.) The present value of £1 due in any number of years, n; or $(1+i)^{-n}$.

(3.) The amount of an annuity of £1 in any number of years, n; or $\frac{(1+i)^n-1}{i}$.

(4.) The present value of an annuity of £1 for any number of years, n; or $\frac{1-(1+i)^{-n}}{i}$.

(5.) The annuity which £1 will purchase for any number of years, n; or $\frac{i}{1-(1+i)^{-n}}$.

The scheme would be more complete if we add, with Corbaux, whose tables will be described below—

(6.) The annuity which would amount to £1 in n years; or $\frac{i}{(1+i)^n-1}$.

Smart gives the values of these functions not only for all integral values of n up to 100, but also for the half-years. In this respect, however, he has not been followed by subsequent writers. Some (as Milne) have stated that he "has given the amounts and the present values both of sums and annuities certain, wrong for every odd number of half-years." This remark requires some explanation. The fact is that Smart's tables are quite correct, but are not applicable according to the conventions that are usually observed in practice. Thus, for example, he gives the amount of 1 at the end of half a year at 4 per cent. interest as equal to $\sqrt{1\cdot04}=1\cdot01980390$, this being the strictly correct theoretical value at 4 per cent. interest. But in practice the invariable rule is, when interest is calculated for a shorter term than a year, to take a proportionate part of the year's interest, thus virtually charging a higher rate for the odd time, so that in the above case the amount at the end of half a year will be 1·02. This circumstance renders it undesirable to tabulate the amounts and values for half-years; and this is never now done. The course adopted by Smart of giving the values and amounts of annuities for the odd half-years is open to more serious objection. His figures in these cases are merely the values of the algebraical functions above given, corresponding to the values of n, $\frac{1}{2}$, $1\frac{1}{2}$, $2\frac{1}{2}$, &c., and do not give the amounts and values of annuities payable half-yearly. In fact, we are unable to see that any practical use could ever be made of his results in these cases.

The following table, on p. 75, in which the rate of interest is 5 per cent., will serve to illustrate the nature of the tables in question, as reprinted by Baily, D. Jones, and others.

It will be seen that the figures in the column numbered (2) are the reciprocals of those in (1), and the figures in column (5) the reciprocals of those in (4). Also, that the figures in (4) are the sums of the first 1, 2, 3, &c., terms of (2). Again, the figures in (3) are derived by the successive addition of those in (1) to the first term, 1·000000; and the figures in (4) are equal to the product of those in (2) and (3). We have added the column (6) from Corbaux's tables. These figures are the reciprocals of those in (3), and are equal to the product of those in (5) and (2), while the figures in (5) are the products of those in (1) and (6).

It would perhaps be more convenient in practice if tables (3) and (6) were altered so as to relate to annuities payable in advance (or annuities-due). In that case (3) would give the amount at compound interest in n years of an annuity-due of 1, and (6) the annuity-due which would, at compound interest, amount to 1 in n years; that is to say, the values of the functions $\frac{(1+i)^{n+1}-1-i}{i}$ and $\frac{i}{(1+i)^{n+1}-1-i}$, respectively. One very common application of table (3) is to find the amount of the premiums paid upon a life policy, and these premiums are always payable in advance. If that table were arranged as here suggested, the figures contained in it would be derived from those in (1), in precisely the same way as

problem of determining the rate of interest in the bonds of foreign governments above mentioned, debentures, and similar securities, has been fully treated of by Gray, *Ass. Mag.*, xiv. 91, 182, 397; and by Makeham, xviii. 132.

Table of Amounts, Present Values, &c., at 5 per cent. Interest.

$i = \cdot 05.$

n	(1) $(1+i)^n$	(2) $(1+i)^{-n}$	(3) $\frac{(1+i)^n-1}{i}$	(4) $\frac{1-(1+i)^{-n}}{i}$	(5) $\frac{i}{1-(1+i)^{-n}}$	(6) $\frac{i}{(1+i)^n-1}$
1	1·05000000	·95238095	1·00000000	·95238095	1·05000000	1·0000000

(4) from (2). It would also be an improvement, for a reason to be mentioned presently, if the heading of the tables were altered, so that, for example, instead of (1) being called a table of the amounts of "£1" at the end of any number of "years," it were called a table of the amounts of "1" at the end of any number of "terms."

It is not to be understood that the tables are arranged in the manner here shown. Smart gives, in his First Table of Compound Interest, the values of our (1) for the various rates of interest arranged side by side; in his Second Table he gives the values of our (2) at different rates of interest similarly arranged; and so for (3), (4), and (5). This arrangement has been followed by most authors, not only by those mentioned above as having copied Smart's tables, but also by Chisholm, who states that the compound interest tables in his work (*Commutation Tables*, 1858) have been specially computed for it. He gives the tables (1), (2), (3), (4), and (5), at the rates of interest 3, 3½, 4, 5, 6 per cent., to any number of years up to 105. Hardy's *Doctrine of Simple and Compound Interest*, 1839, contains tables (1), (2), (3), (4), for the rates of interest ¼, ½, ¾, 1, 1¼, 1½, 1¾, 2, 2¼, 2½, 2¾, 3, 3¼, 3½, 3¾, 4, 4¼, 4½, 4¾, 5, 6, 7, and 8 per cent., for any number of years up to 100. The arrangement in our specimen is that adopted by Rance in his *Tables of Compound Interest*, 1852. He gives tables (1), (2), (3), and (4), at rates of interest proceeding, by steps of ¼ per cent., from ¼ to 10 per cent., for any number of years from 1 to 100. The same arrangement is also followed in the tables appended to Francis Corbaux's *Doctrine of Compound Interest*, 1825; but this author gives in one opening of the book not only the six tabular results in our specimen, but also the corresponding results when interest at the nominal rate of 5 per cent. is payable half-yearly and quarterly, thus giving in one opening 24 tabular results side by side. He gives results for every quarter of a year up to 16 years, and then for each year up to 100; and his rates of interest range from 3 to 6 per cent., at intervals of ¼ per cent. The only other tables we think it needful to mention are Turnbull's, 1863. His work gives tables (1), (2), (3), (4), and (5), for the rates of interest 3, 3½, 4, 4½, 5, and 6, payable yearly; for 3, 3¼, 3½, 3¾, 4, 4¼, 4½, 4¾, 5, 5½, payable half-yearly; and 3, 3½, 4, 4½, 5, 6, payable quarterly. The results extend in every case to 80 terms of conversion—that is, 80 years, 80 half-years, and 80 quarters respectively. The arrangement of the tables differs from that of all the others mentioned, as each page contains only the results pertaining to one table at one rate of interest. The results are given not only in decimals, but in £ *s. d.* in addition, which also is unusual.

A few words may be here added as to the practical method of constructing compound interest tables. The formulas we have found above are not directly used for the calculation of the greater part of the tabular results; but these are in practice deduced the one from the other by continuous processes, the values found by the formulas being used at intervals for the purpose of verification. Smart gives, on page 47 of his work, a description of the method he has employed, and the subject has been fully dealt with by Gray in his *Tables and Formulæ*, chap. 2. Since the publication of that work, the Arithmometer of M. Thomas (of Colmar) has come into extensive use for the formation of tables of this kind. For a description of the instrument, and some of its uses, the reader is referred to the papers in the *Assurance Magazine* by Major-General Hannyngton, vol. xvi. p. 244; Mr W. J. Hancock, xvi. 265; and by Gray, xvii. 249; xviii. 20 and 123.

Hitherto we have considered the annuity payments to be all made annually; and the case where the payments are made more frequently now requires attention. First, suppose that the annuity is payable by half-yearly instalments; then, in order to find the present value of the annuity, we have first to answer the question, What is the value of a sum payable in six months' time? and, in order to find the amount of the annuity in n years, we must first determine what is the amount of a sum at the end of six months. The annual rate of interest being i, it may be supposed at first sight that the amount of 1 at the end of six months will be $1+\frac{i}{2}$; but if this were the case, the amount at the end of a second period of six months would be increased in the same proportion, and be $\left(1+\frac{i}{2}\right)^2$, or $1+i+\frac{i^2}{4}$. But this is contrary to our original assumption that the annual interest is i, and the amount at the end of a year therefore $1+i$. In fact, if we suppose the interest on 1 for half a year to be $\frac{i}{2}$, the interest on it for a year will not be i, but $i+\frac{i^2}{4}$. In order that the amount at the end of a year may be $1+i$, the amount at the end of six months must be such a quantity as, improved at the same rate for another six months, will be exactly $1+i$; hence the amount at the end of six months must be $\sqrt{1+i}$, or $(1+i)^{\frac{1}{2}}$. Reasoning in the same way, it is easy to see that, the true annual rate of interest being i, the amount of 1 in any number of years, n, whether integral or fractional, will always be $(1+i)^n$. Hence, by similar reasoning to that pursued above, the present value of 1 payable at the end of any number of years, n, whether integral or fractional, will always be $(1+i)^{-n}$ or v^n.

It is now easily seen—we omit the demonstrations for the sake of brevity—that the present value of an annuity payable half-yearly for n years (n being integral) is $\frac{\sqrt{1+i}+1}{2} \cdot \frac{1-(1+i)^{-n}}{i}$; and that the amount of a similar annuity at the end of n years is $\frac{\sqrt{1+i}+1}{2} \cdot \frac{(1+i)^n-1}{i}$.

It is to be observed, however, that when we are dealing with half-yearly payments in practice, the interest is never calculated in the way we have here supposed. On the contrary, the nominal rate of interest being i, the rate paid half-yearly is $\frac{i}{2}$, so that the true annual rate in practice is $i+\frac{i^2}{4}$; for instance, if interest on a loan is payable half-yearly, at the rate of 5 per cent. per annum, the true rate of interest is ·050625, or £5, 1s. 3d. per £100. Under these circumstances interest is said to be convertible into principal twice a year. Assuming that interest is thus convertible m times a year, the rate of interest for the m^{th} part of a year will be $\frac{i}{m}$, and the amount of 1 at the end of n years, that is, at the end of mn intervals of conversion, will be $\left(1+\frac{i}{m}\right)^{mn}$. Assuming the number m now to increase indefinitely, or interest to be convertible momently, the above amount becomes $\epsilon^{i n}$, where ϵ is the base of the natural (or Napierian) logarithms.

In consequence of the above-mentioned practice as to half-yearly interest, the values given in Smart's tables for the odd half-years, though theoretically correct, are practically useless, and they have been superseded by the other tables above mentioned. It is important, however, always to bear in mind that when interest is thus payable half-yearly or quarterly, the true rate of interest exceeds the nominal. From want of attention to this point, the subject has become involved in much confusion, not to say error, in the works of Milne and some other writers.

It is easily seen from the above formula that the amount of 1 in mn years, at the rate of interest $\frac{i}{m}$, is the same as that of 1 in n years, at the rate of interest i convertible m times a year; and a similar property holds good of present values. Hence, the tables calculated at the rate of interest $\frac{i}{m}$ may be used to find the amounts and present values at the rate i convertible m times a year; for example, the tables calculated for interest 2 per cent. will give the results for 4 per cent. payable half-yearly. For this reason it would be an improvement, as remarked above, to use the word "terms" in the headings of the tables instead of "years."

We pass on now to the consideration of the theory of life annuities. This is based upon a knowledge of the rate of mortality among mankind in general, or among the particular class of persons on whose lives the annuities depend. If a simple mathematical law could be discovered which the mortality followed, then a mathematical formula could be given for the value of a life annuity, in the same way as we gave above the formula for the value of an annuity certain. In the early stage of the science, Demoivre propounded the very simple law of mortality which bears his name, and which is to the effect, that out of 86 children born alive 1 will die every year until the last dies between the ages of 85 and 86. The mortality, as determined by this law, agreed sufficiently well at the middle ages of life with the mortality deduced from the best observations of his time; but, as observations became more exact, the approximation was found to be not sufficiently close. This was particularly the case when it was desired to obtain the value of joint life, contingent, or other complicated benefits. Demoivre's law is now, accordingly, entirely a thing of the past, and does not call for any further notice from us. Assuming that law to hold, it is easy to obtain the formula for the value of an annuity, immediate, deferred, or temporary; but such formulas are entirely devoid of practical utility. Those who are curious on the subject may consult the paper by Charlon, *Ass. Mag.*, xv. 141. In vol. vi. p. 181, will be found an investigation by Gray of the formula for the value of an annuity when the mortality table is supposed to follow a somewhat more complicated law. No simple formula, however, has yet been discovered that will represent the rate of mortality with sufficient accuracy, and those which satisfy this condition are too complicated for general use.

The rate of mortality at each age is, therefore, in practice usually determined by a series of figures deduced from observation; and the value of an annuity at any age is found from these numbers by means of a series of arithmetical calculations. Without entering here on a description of the manner of making these observations and deducing the rate of mortality, and of the construction of "Mortality Tables," we append, for the sake of illustration, one of the earliest tables of this kind, namely, that of Deparcieux, given in his *Essai sur les Probabilités de la Durée de la Vie Humaine*, 1746.

Age. x	Number living. l_x	Number dying in the next year. d_x	Age. x	Number living. l_x	Number dying in the next year. d_x	Age. x	Number living. l_x	Number dying in the next year. d_x
3	1000	30	34	702	8	65	395	15
4	970	22	35	694	8	66	380	16

27	758	8	58	489	13	89	16	5
28	750	8	59	476	13	90	11	4
29	742	8	60	463	13	91	7	3
30	734	8	61	450	13	92	4	2
31	726	8	62	437	14	93	2	1
32	718	8	63	423	14	94	1	1
33	710	8	64	409	14	95	0	

It is to be understood from this table that the mortality among the persons observed was such that out of every 1000 children alive at the age of 3, 30 died before attaining the age of 4, leaving 970 alive at 4; 22 died between the ages of 4 and 5, leaving 948 alive at the age of 5; and so on, until one person is left alive at the age of 94, who died before attaining the age of 95.

For the purpose of explaining more fully the method of finding the value of a life annuity, it will be convenient, in the first instance, to establish the two following lemmas.

LEMMA 1. *To find the value of a sum to be received at a future time in the event of the happening of a given contingency.*—Suppose that the sum of 1 is to be received in n years' time, provided that a certain event shall then happen (or shall have then happened), the probability of which is p. We have seen that the value of 1 to be certainly received in n years' time is v^n. In order to introduce the idea of probability into the problem, suppose that $p=\frac{a}{a+b}$, so that there are a cases favourable to the happening of the assumed event, and b unfavourable, the total number of possible cases, all of which are equally probable, being $(a+b)$. We may suppose, for instance, that there are $(a+b)$ balls in a bag, of which a are white and b black; and that 1 is to be received if a white ball is drawn. In order to determine the value of the chance of receiving 1 in consequence of a white ball being drawn, suppose that $(a+b)$ persons draw each one ball, and that every one who draws a white ball receives 1; then the total sum to be received is a, and the value of the expectation of all the $(a+b)$ persons who draw is also a. But it is clear that each of the persons has the same chance of drawing a white ball, therefore the value of the expectation of each of them is $\frac{a}{a+b}=p$. This is the value of the chance of receiving 1 immediately before the drawing is made in

n years' time; the value at the present time will therefore be $v^n p$. We may also arrive at this result as follows: The same suppositions being still adhered to, the present value of the sum a to be distributed at the end of n years is av^n; and each of the $(a+b)$ persons having the same chance of receiving 1, the value of the expectation of each is $\frac{a}{a+b}v^n = pv^n$.

LEMMA 2. *To find the present value of 1 to be received in n years' time, if a specified person, whose age is now x, shall be then living.*—The sum to be received in this case is called an *endowment*, and the person on whose life it depends is called the *nominee*. The probability that the nominee will be alive is to be found, as already intimated, by means of a mortality table. Out of the various tables of this nature that exist, that one must be chosen which, it is believed, most faithfully represents the probabilities of life of the class of persons to which the nominee belongs. Suppose we have reason to believe that Deparcieux's table, above given, is the most suitable in the case before us,—that the age of the nominee is 30, and the term of years 10. Then, observing that, according to Deparcieux's table, the number of persons living at the age 30 is 734, while the number at the age 40 is 657, and the difference, or the number who die between the two ages, is 77, we conclude that the chances of any particular nominee of the age of 30 dying before attaining the age of 40 are as 77 to 734, and the chances in favour of his living to the age of 40 are as 657 to 734; or the probability of his living to 40 is $\frac{657}{734}$.

Passing now from figures to more general symbols, we will use l_x to denote the number given in the mortality table as alive at any age x; so that, for example, in the above table, $l_{30}=734$, $l_{40}=657$; and in accordance with what we have just explained, the probability of a nominee of the age x living to the age $x+n$, will therefore be expressed by $\frac{l_{x+n}}{l_x}$. Hence, by lemma 1, the value of 1 to be received if the nominee shall be alive at the end of n years, is $\frac{l_{x+n}}{l_x}v^n$. In the particular case supposed above, the actual value will be, taking the rate of interest at 3 per cent., $\frac{657}{734}\times(1{\cdot}03)^{-10} = {\cdot}666035$. We may look at the question from another point of view. Suppose that 734 persons of the age of 30 agree to purchase from an insurance company each an endowment of £1, payable at the end of 10 years, then the probabilities of life being supposed to be correctly given by Deparcieux's table, we see that 657 of those persons will be alive at the end of 10 years, or the engagement of the insurance company to pay £1 to each survivor amounts to the same thing as the engagement to pay £657 at the end of 10 years, and the present value of this sum is $657\ (1{\cdot}03)^{-10}$. The sum that should be paid by each of the 734 persons, so that the company shall neither gain nor lose by the transaction, is therefore $\frac{657}{734}(1{\cdot}03)^{-10}$, as before. If we suppose the probabilities of life to agree with those of the English Table, No. 3, Males, which is printed at the end of this article, the value of the same endowment will be—

$$\frac{272{,}073}{304{,}534}(1{\cdot}03)^{-10} = {\cdot}664779\ .$$

If now we carefully examine the reasoning of the last paragraph, we see that we have made an assumption that must not be allowed to pass without some further justification. We have assumed, in fact, that the lives we are dealing with will die off at the exact rate indicated by the mortality table. This, however, we know, is not necessarily the case. Even if the mortality table correctly represents in the long run the rate of mortality among the lives we are dealing with, we know that the rate of mortality will, from accidental circumstances, be sometimes greater and sometimes less than that indicated by the table. If, for example, we have 734 persons under observation all of the age 30, we have no certainty that at the end of 10 years exactly 77 will have died, leaving 657 alive. It is, indeed, within the range of possibility—firstly, that the whole 734 persons may die before the age 40; and, secondly, that none of them may die, or that the whole 734 may attain the age of 40. It appears, therefore, as if we had used the word "probability" in the second lemma in a different sense from that we attached to it in the first; for, in that case we know that if the whole of the $(a+b)$ balls are drawn, a of them will certainly be white, and b black. But the cases will be more parallel if we suppose that each of the balls, after being drawn, is replaced in the bag. If this is done, we see it is no longer certain that when $(a+b)$ drawings take place, a of the balls will be white, and b black. It may, under these altered circumstances, possibly happen that the balls drawn at each of the $(a+b)$ drawings will all be white, or on the contrary all black. But when a very large number of drawings are made, we can prove that the ratio of white balls drawn to the black will differ very little from the ratio of a to b, and will exactly equal it if the number of drawings is supposed to be indefinitely large. In this case we know that the probability of drawing a white ball is still $\frac{a}{a+b}$, and passing now to the case of lives under observation, we can say, in the same sense, that the probability of a person of the age of 30 living for 10 years is, according to Deparcieux's table, $\frac{657}{734}$, and that on the average of a very large number of observations, that fraction will accurately represent the number of persons surviving. We shall, therefore, be justified in basing all our reasonings on the assumption that the lives we are dealing with die precisely at the rate indicated by the figures of the mortality table.

We are now in a position to show how the value of a life annuity is calculated. The annual payment of the annuity being 1, which is to be made at the end of each year through which the nominee shall live, the annuity consists of a payment of 1 at the end of one year if the nominee is then alive, of the same payment at the end of two years, at the end of three years, &c., under the same condition, and is therefore equal to the sum of a series of endowments. If x is the age of the nominee, the value of the endowment to be received at the end of the nth year is, as we have seen in lemma 2, $\frac{l_{x+n}}{l_x}v^n$, and the total value of the annuity is therefore

$$\frac{l_{x+1}}{l_x}v + \frac{l_{x+2}}{l_x}v^2 + \frac{l_{x+3}}{l_x}v^3 + \ .\ .\ .\ . \qquad \text{(I.)}$$

By means of this formula, taking the values of l_x, l_{x+1}, l_{x+2}, &c., from the mortality table, and calculating the values of v, v^2, v^3, &c., according to the desired rate of interest, or taking their values from the compound interest tables previously described, we can calculate the value of an annuity at any age with any degree of accuracy desired. In practice the calculations would be most readily made by the aid of logarithms.

We can arrive at the above formula more readily by availing ourselves of the supposition which we have seen to be allowable, that the lives under observation will die off exactly at the rate indicated by the mortality table.

Thus, suppose that l_x persons of the age x buy each an annuity of 1. Then the number of persons who will survive to the age $x+1$, and claim the first payment of the annuity, will be l_{x+1}. The value of 1 to be paid at the end of a year is v, and therefore the present sum that will be required to provide for all the payments at the end of the first year will be $l_{x+1}v$. The number of persons who will survive two years, so as to claim the second year's payment, will be l_{x+2}; and multiplying this into the value of 1 payable at the end of two years, we get $l_{x+2}v^2$ as the present sum necessary to provide for the payments at the end of the second year. Proceeding in this way, the total sum that will be required to provide the annuities to the l_x persons, will be $l_{x+1}v+l_{x+2}v^2+l_{x+3}v^3+\ldots$ Hence the value of an annuity on a nominee of the age x, or the sum that will on the average be required to provide for such an annuity, will be

$$\frac{l_{x+1}v+l_{x+2}v^2+l_{x+3}v^3+\ldots\ldots}{l_x}\quad\ldots\quad(2.)$$

which is at once seen to be the same as (1) formula under another shape.

If we suppose money to bear no interest, or make $v=1$ in the formula for the value of an annuity, we shall obtain a quantity which is called the "expectation of life," or the "average duration of life," being the average number of years which persons of the given age will one with another live. Denoting this by e_x, and making $v=1$ in the formula above given, we get

$$e_x=\frac{l_{x+1}+l_{x+2}+l_{x+3}+\ldots}{l_x}.$$

As in the formula for the annuity, no payment is made on account of the year in which the nominee dies, this formula gives the average number of *complete* years that persons of the given age will live according to the mortality table, and makes no allowance for the portion of the year in which death occurs. The expectation thus found is called the curtate expectation; and in order to obtain the complete expectation of life, which is denoted by $\mathring{e}_x$, half a year must be added to it.

The first writer who is known to have attempted to obtain, on correct mathematical principles, the value of a life annuity, was Johan De Wit, Grand Pensionary of Holland and West Friesland. All our exact knowledge of his writings on the subject is derived from two papers contributed by Mr Frederick Hendriks to the *Assurance Magazine*, vol. ii. p. 222, and vol. iii. p. 93. The former of these contains a translation of De Wit's report upon the value of life annuities, which was prepared in consequence of the resolution passed by the States General, on the 25th April 1671, to negotiate funds by life annuities, and which was distributed to the members on the 30th July 1671. The latter contains the translation of a number of letters addressed by De Wit to Burgomaster Johan Hudde, bearing dates from September 1670 to October 1671. The existence of De Wit's report was well known among his contemporaries, and Mr Hendriks has collected a number of extracts from various authors referring to it; but the report is not contained in any collection of his works extant, and had been entirely lost for 180 years, until Mr Hendriks conceived the happy idea of searching for it among the state archives of Holland, when it was found together with the letters to Hudde. It is a document of extreme interest, and (notwithstanding some inaccuracies in the reasoning) of very great merit, more especially considering that it was the very first document on the subject that was ever written; and Mr Hendriks's papers will well repay a careful perusal.

It appears that it had long been the practice in Holland for life annuities to be granted to nominees of any age, in the constant proportion of double the rate of interest allowed on stock; that is to say, if the towns were borrowing money at 6 per cent., they would be willing to grant a life annuity at 12 per cent.; if at 5 per cent., the annuity granted was 10 per cent.; and so on. De Wit states that "annuities have been sold, even in the present century, first at six years' purchase, then at seven and eight; and that the majority of all life annuities now current at the country's expense were obtained at nine years' purchase;" but that the price had been increased in the course of a few years from eleven years' purchase to twelve, and from twelve to fourteen. He also states that the rate of interest had been successively reduced from 6¼ to 5 per cent., and then to 4 per cent. The principal object of his report is to prove that, taking interest at 4 per cent., a life annuity was worth at least sixteen years' purchase; and, in fact, that an annuitant purchasing an annuity for the life of a young and healthy nominee at sixteen years' purchase, made an excellent bargain. It may be mentioned that he argues that it is more to the advantage, both of the country and of the private investor, that the public loans should be raised by way of grant of life annuities rather than perpetual annuities. It appears conclusively from De Wit's correspondence with Hudde, that the rate of mortality assumed as the basis of his calculations was deduced from careful examination of the mortality that had actually prevailed among the nominees on whose lives annuities had been granted in former years. De Wit appears to have come to the conclusion that the probability of death is the same in any half-year from the age of 3 to 53 inclusive; that in the next ten years, from 53 to 63, the probability is greater in the ratio of 3 to 2; that in the next ten years, from 63 to 73, it is greater in the ratio of 2 to 1; and in the next seven years, from 73 to 80, it is greater in the ratio of 3 to 1; and he places the limit of human life at 80. If a mortality table of the usual form is deduced from these suppositions, out of 212 persons alive at the age of 3, 2 will die every year up to 53, 3 in each of the ten years from 53 to 63, 4 in each of the next ten years from 63 to 73, and 6 in each of the next seven years from 73 to 80, when all will be dead. This is the conclusion we have drawn from a careful study of the report; but, in consequence of the inaccuracies above mentioned, some doubt exists as to De Wit's real meaning; and Mr Hendriks's conclusion is somewhat different from ours (see his note, *Ass. Mag.* vol. ii. p. 246). The method of calculation employed by De Wit differs much from that described above, and a short account of it may interest the reader. Suppose that it were desired to apply it to deduce the value of an annuity according to Deparcieux's mortality table given above, then we assume that annuities are bought on the lives of 1000 nominees each 3 years of age. Of these nominees, 30 will die before attaining the age of 4, and no annuity payment will be made in respect of them; 22 will die between the ages of 4 and 5, so that the holders of the annuities on their lives will receive payment for 1 year; 18 attain the age of 5 and die before 6, so that the annuities on their lives are payable for 2 years. Reasoning in the same way, we see that the annuities on 15 of the nominees will be payable for 3 years; on 13, for 4 years; on 12, for 5 years; on 10, for 6 years; and so on. Proceeding thus to the extremity of the table, 2 nominees attain the age of 93, 1 of whom dies before the age of 94, so that 90 annuity payments will be made in respect of him; and the last survivor dies between the ages of 94 and 95, so that the annuity on his life will be payable for 91 years. Having previously calculated a table of the values of annuities certain for every number of years up to 91, the value of all the annuities on the

1000 nominees will be found by taking twenty-two times the value of an annuity for 1 year, eighteen times the value of an annuity for 2 years, fifteen times the value of an annuity for 3 years, and so on,—the last term being the value of 1 annuity for 91 years,—and adding them together; and the value of an annuity on one of the nominees will then be found by dividing by 1000. Before leaving the subject of De Wit, we may mention that we find in the correspondence a distinct suggestion of the law of mortality that bears the name of Demoivre. In De Wit's letter, dated 27th October 1671 (*Ass. Mag.*, vol. iii. p. 107), he speaks of a "provisional hypothesis" suggested by Hudde, that out of 80 young lives (who, from the context, may be taken as of the age 6) about 1 dies annually. In strictness, therefore, the law in question might be more correctly termed Hudde's than Demoivre's.

De Wit's report being thus of the nature of an unpublished state paper, although it contributed to its author's reputation, did not contribute to advance the exact knowledge of the subject; and the author to whom the credit must be given of first showing how to calculate the value of an annuity on correct principles is Dr Edmund Halley, F.R.S. In the *Philosophical Transactions*, Nos. 196 and 198 (January and March 1693), he gave the first approximately correct mortality table (deduced from the records of the numbers of deaths and baptisms in the city of Breslau), and showed how it might be employed to calculate the value of an annuity on the life of a nominee of any age. His method of procedure exactly agrees with the formula (1) above given; and while he confesses that it requires a series of laborious calculations, he says that he had sought in vain for a more concise method. His papers, which are full of interest, are reprinted in the eighteenth volume of the *Assurance Magazine*.

Previous to Halley's time, and apparently for many years subsequently, all dealings with life annuities were based upon mere conjectural estimates. The earliest known reference to any estimate of the value of life annuities rose out of the requirements of the Falcidian law, which (40 B.C.) was adopted in the Roman empire, and which declared that a testator should not give more than three-fourths of his property in legacies, so that at least one-fourth must go to his legal representatives. It is easy to see how it would occasionally become necessary, while this law was in force, to value life annuities charged upon a testator's estate. Æmilius Macer (230 A.D.) states that the method which had been in common use at that time was as follows:—From the earliest age until 30 take 30 years' purchase, and for each age after 30 deduct 1 year. It is obvious that no consideration of compound interest can have entered into this estimate; and it is easy to see that it is equivalent to assuming that all persons who attain the age of 30 will certainly live to the age of 60, and then certainly die. Compared with this estimate, that which was propounded by the Prætorian Prefect Ulpian—one of the most eminent commentators on the Justinian Code—was a great improvement. His table is as follows:—

Age.	Years' Purchase.	Age.	Years' Purchase.
Birth to 20	30	45 to 46	14
20 ,, 25	28	46 ,, 47	13
25 ,, 30	25	47 ,, 48	12
30 ,, 35	22	48 ,, 49	11
35 ,, 40	20	49 ,, 50	10
40 ,, 41	19	50 ,, 55	9
41 ,, 42	18	55 ,, 60	7
42 ,, 43	17	60 and upwards	5
43 ,, 44	16		
44 ,, 45	15		

Here also we have no reason to suppose that the element of interest was taken into consideration; and the assumption, that between the ages of 40 and 50 each addition of a year to the nominee's age diminishes the value of the annuity by one year's purchase, is equivalent to assuming that there is no probability of the nominee dying between the ages of 40 and 50. Considered, however, simply as a table of the average duration of life, the values are fairly accurate. At all events, no more correct estimate appears to have been arrived at until the close of the 17th century. Fuller information upon the early history of life annuities will be found in the article "Annuities on Lives, History of," in Mr Walford's *Insurance Cyclopædia*.

Demoivre, in his *Treatise on Annuities*, 1725, showed that it was unnecessary to go through the whole of the calculation indicated by the formula (1) or (2) for each age, and that the value of an annuity at any age might be deduced by a simple process from that at the next older age. This may be demonstrated as follows:—If it were certain that a person of any age, say 39, would live for a year, then the value of an annuity on his life would be such a sum as would increase at interest in a year to the value of an annuity on a life one year older, say 40, increased by a present payment of 1; that is, putting a for the value of an annuity and ${}^1a$ for that on a life one year older, the value would be $v(1+{}^1a)$. But it is uncertain that the life will exist to the end of a year, and the value of the annuity must therefore be reduced in the proportion of this uncertainty, or be multiplied by the probability that the given life will survive a year. Putting then p to denote this probability, we have $a = vp\,(1+{}^1a)$. This formula may also be demonstrated algebraically. We have seen that

$$a = v\frac{{}^1l}{l} + v^2\frac{{}^2l}{l} + v^3\frac{{}^3l}{l} + \ldots\ldots + v^z\frac{{}^zl}{l},$$

where z is the difference between the age of the given life and that of the oldest in the mortality table. (Assuming the present age to be 39, then in the English Table No. 3, Males, z will be $107-39=68$.) In the same way, we have

$${}^1a = v\frac{{}^2l}{{}^1l} + v^2\frac{{}^3l}{{}^1l} + v^3\frac{{}^4l}{{}^1l} + \ldots\ldots + v^{z-1}\frac{{}^zl}{{}^1l}.$$

$$\text{Hence } a = v\frac{{}^1l}{l}\left(1 + v\frac{{}^2l}{{}^1l} + v^2\frac{{}^3l}{{}^1l} + \ldots\ldots + v^{z-1}\frac{{}^zl}{{}^1l}\right)$$

$$= v\frac{{}^1l}{l}(1+{}^1a)$$

$$= vp(1+{}^1a)$$

—the same result as already proved.

If we suppose the present age to be x, we may put the formula in the shape

$$a_x = v\frac{l_{x+1}}{l_x}(1+a_{x+1});$$

but it will be found preferable to omit the subscript x whenever this can be done without risk of confusion.

This formula has been commonly attributed to Simpson, who in 1742 published his *Doctrine of Annuities and Reversions;* but, although he certainly showed that it is applicable to annuities on the joint duration of two or more lives, the first discovery of it is undoubtedly due to Demoivre. (See Farren's *Historical Essay on the Use and early Progress of the Doctrine of Life Contingencies in England*, p. 46.) The formula appears to have been independently discovered by Euler, and was given by him in a paper in the *Memoirs of the Royal Academy of Sciences at Berlin*, for the year 1760.

Mr Peter Gray has shown in his *Tables and Formulæ*, 1849, how Gauss's logarithmic table may be advantageously employed in calculating the values of annuities by the above formula. That table gives us the value of log $(1+a)$ when that of log a is known. In other words, the argument of the table is log a, and the tabular result is log $(1+a)$. When ordinary logarithmic tables are used, the formulas being

$$\log a_x = \log vp_x + \log(1+a_{x+1}),$$
$$\log a_{x-1} = \log vp_{x-1} + \log(1+a_x);$$

we have to find a_x by means of an inverse entry into the table before $\log(1+a_x)$ can be found; but when Gauss's table is used (as recomputed and extended by Gray), "All the entries of the same kind—direct and inverse—are brought together, the whole of the logarithms being found before a single natural number is taken out. We consequently proceed right through the table; and as we proceed, we find two, three, four, and even as many as six and eight entries on the same opening. At the close, moreover, the taking out of the numbers may, if necessary, be turned over to an assistant. On the other hand, when the common tables are used, direct and inverse entries alternate with each other, and involve likewise a continual turning of the leaves backwards and forwards, by which the process is rendered exceedingly irksome."—Page 165, second issue, 1870.

When the only object is to form a complete table of immediate annuities, the above is the simplest and most expeditious mode of procedure; but when it is desired to have the means of obtaining readily the values of deferred and temporary annuities, it is better to employ a wholly different method.

The value of a deferred annuity may be found as follows. —If it were certain that the nominee, whose age is supposed to be now x, would survive n years, so as to attain the age of $x+n$, the value of the annuity on his life being then a_{x+n}, its present value would be $v^n a_{x+n}$. But as the nominee may die before attaining the age of $x+n$, the above value must be multiplied by the probability of his living to that age, which is $\frac{l_{x+n}}{l_x}$, and we thus get the present value of the deferred annuity, $v^n \cdot \frac{l_{x+n}}{l_x} \cdot a_{x+n}$. We may arrive at this result otherwise. Thus, as we have seen above, the present value of the first payment of the annuity, that is, of 1 to be received if the nominee shall be alive at the end of $n+1$ years, is $\frac{{}^{n+1}l}{l}v^{n+1}$ The present value of the next payment is similarly seen to be $\frac{{}^{n+2}l}{l}v^{n+2}$, and so on. The value of the deferred annuity is therefore

$$\frac{{}^{n+1}l}{l}v^{n+1} + \frac{{}^{n+2}l}{l}v^{n+2} + \frac{{}^{n+3}l}{l}v^{n+3} + \ldots\ldots\ldots$$
$$= \frac{{}^{n}l}{l}v^n\left\{\frac{{}^{n+1}l}{{}^{n}l}v + \frac{{}^{n+2}l}{{}^{n}l}v^2 + \frac{{}^{n+3}l}{{}^{n}l}v^3 + \ldots\ldots\right\}$$
$$= \frac{{}^{n}l}{l}v^n \cdot {}^{n}a, \left(\text{or } \frac{l_{x+n}}{l_x} \cdot v^n \cdot a_{x+n}\right).$$

(We may here mention that this formula holds good, not only for ordinary annuities, but also for annuities payable half-yearly or quarterly, and for continuous annuities; also for complete annuities.)

A temporary annuity is, as explained above, an annuity which is to continue for a term of years provided the nominee shall so long live. Hence it is clear that if the value of a temporary annuity for n years is added to that of an annuity on the same life deferred n years, this sum must be equal to an annuity for the whole continuance of the same life; the value of a temporary annuity for n years will therefore be equal to the difference between the value of a whole term annuity and that of an annuity deferred n years, or to

$$a - \frac{{}^{n}l}{l}v^n \cdot {}^{n}a, \left(\text{or } a_x - \frac{l_{x+n}}{l_x}\ v^n a^{x+n}\right).$$

We are now in a position to explain the method of calculating the value of annuities above referred to. We have seen that the value of an annuity for the life of a nominee whose age is x, is

$$\frac{l_{x+1}v + l_{x+2}v^2 + \ \ldots\ldots + l_{x+s}v^s}{l_x};$$

which, multiplying both numerator and denominator by the same quantity v^x, becomes

$$\frac{l_{x+1}v^{x+1} + l_{x+2}v^{x+2} + \ \ldots\ldots + l_{x+s}v^{x+s}}{l_x v^x}$$

In the same way, the value of an annuity on the same life, deferred n years, is

$$\frac{l_{x+n+1}}{l_x}v^{n+1} + \frac{l_{x+n+2}}{l_x}v^{n+2} + \ \ldots\ldots + \frac{l_{x+s}}{l_x}v^s.$$
$$= \frac{l_{x+n+1}v^{n+1} + l_{x+n+2}v^{n+2} + \ \ldots\ldots + l_{x+s}v^s}{l_x}$$
$$= \frac{l_{x+n+1}v^{x+n+1} + l_{x+n+2}v^{x+n+2} + \ \ldots\ldots\ldots + l_{x+s}v^{x+s}}{l_x v^x}.$$

If, then, we calculate in the first instance the values of the product $l_x v^x$ for all values of x, and then form their sums, beginning at the highest age, we shall have the means of obtaining by a single division the value of any immediate or deferred annuity we wish.

It is convenient to arrange these results in a tabular form, as shown in the appended tables (3) and (4). The quantity $l_x v^x$ is placed in the column headed D, opposite the age x, and is denoted by D_x; while the sum $l_{x+1}v^{x+1} + l_{x+2}v^{x+2} + \ \ldots\ldots + l_{x+s}v^{x+s}$ is placed in the column headed N, opposite the same age x, and is denoted by N_x; so that the value of an immediate annuity on a life x is equal to $\frac{N_x}{D_x}$; the letters N and D being chosen as the first letters of the words Numerator and Denominator. Then it is easy to see that the value of an annuity on x deferred n years is equal to $\frac{N_{x+n}}{D_x}$; whence by subtraction the value of a temporary annuity for n years on the same life is $\frac{N_x - N_{x+n}}{D_x}$.

If, for example, we wish to find the value of an annuity on a male life of 40 according to the English Table No. 3, with interest at 3 per cent., we find from table (3) appended to this article, $N_{40} = 1374058$, $D_{40} = 83406$, and by division we get the value of $\frac{N_{40}}{D_{40}} = 16{\cdot}4744$, which agrees with the value contained in the table (5), also appended to this article.

Next, suppose we wish to find the value of a deferred annuity on a life of 30 to commence at the end of 10 years. From what precedes, we see that the value of this annuity will be equal to the quotient $\frac{N_{40}}{D_{30}}$ or $\frac{1374058}{125464}$, which will be found to be equal to 10·9518.

If we wish to find the value of this deferred annuity without using the D and N table, the formula for it will be $\frac{l_{40}}{l_{30}}v^{10}a_{40}$, v being equal to $\frac{1}{1{\cdot}03}$. But we have seen above that the value of $\frac{l_{40}}{l_{30}}(1{\cdot}03)^{-10} = {\cdot}664779$, and that $a_{40} = 16{\cdot}4744$; and multiplying these together, we get the value of the deferred annuity, 10·9518, as before.

We have, in conformity with popular usage, called our auxiliary table a "D and N table." It is also called a "commutation table"—a name proposed by De Morgan

In his paper "On the Calculation of Single Life Contingencies," which appeared in the *Companion to the Almanac* for the year 1840, and which is reprinted in the *Assurance Magazine*, xii. 328. His explanation of the term is to the following effect:—Taking any two ages, say 30 and 40, we have, according to the English Table No. 3, Males—see appended table (3),—

$$D_{30} = 125464\,,\ N_{30} = 2385610;$$
$$D_{40} = \ 83406\,,\ N_{40} = 1374058.$$

Transpose the numbers opposite each age to the other age; then whatever may be the present age (less than 30)—

A person might now give up £83,406, due at the age of 30, to receive £125,464, if he live to be 40.

A person might now give up an annuity of £1,374,058, to be granted at the age of 30, to receive in return another of £2,385,610 to be granted at the age of 40, if he should live so long.

"These proportions are independent of the present age of the party, and show that the most simple indication of the tables is the proportion in which a benefit due at one age ought to be changed, so as to retain the same value and be due at another age. They might, therefore, with great propriety, be called *Commutation Tables.*"

It is clear that this property will not be altered if all the quantities in the D column, and consequently those in the N column, are increased or diminished in a constant ratio.

A "D and N table" may be used, not only to find the value of annuities, immediate, deferred, and temporary, but also to find the annual premium that should be paid for a given number of years as an equivalent for a deferred annuity. If the annuity is deferred n years, and the annual premium of equal value is to be paid for m years, it will be $\frac{N_{x+n}}{N_{x-1}-N_{x+m-1}}$. The table may also be used to find the single and annual premiums for insurances, immediate, deferred, or temporary. The single premiums are—

1. For an ordinary insurance, $\frac{vN_{x-1}-N_x}{D_x}$;
2. For an insurance deferred n years, $\frac{vN_{x+n-1}-N_{x+n}}{D_x}$.
3. For a temporary insurance for n years,

$$\frac{v(N_{x-1}-N_{x+n-1})-N_x+N_{x+n}}{D_x}$$

The annual premiums payable during life for the same benefits are found by substituting N_{x-1} for D_x in the denominator; and the annual premiums payable for m years, by putting $N_{x-1}-N_{x+m-1}$ in the denominator instead of D_x.

Before quitting this subject, we should mention that in practice other columns are added to the table besides the D and N columns. A column, S, is given for the purpose of calculating the values of increasing annuities; a column, M, for calculating the values of assurances; and a column, R, for calculating the values of increasing assurances. An explanation of the M column belongs to the subject INSURANCE; for an account of the S and R columns, we refer the reader to the works and papers on life insurance contingencies, in which the D and N (or commutation) method is described; particularly to those of David Jones, Gray, and De Morgan.

The earliest known specimen of a commutation table is contained in William Dale's *Introduction to the Study of the Doctrine of Annuities*, published in 1772. A full account of this work is given by Mr F. Hendriks in the second number of the *Assurance Magazine*, pp. 15–17. Dale's table, as there quoted, differs from the one above described in that it commences only at the age of 50, and that he has tabulated $l_x v^{x-50}$ instead of $l_x v^x$. He says, "These calculations being made for the use of the societies in particular who commence annuitants at the age of 50, it was not thought necessary to begin the tables at a younger age." He gives, however, another table based on different mortality observations, commencing at the age of 40; and in this case he tabulates $l_x v^{x-40}$. His table also differs from the common form in that it is adapted to find the values of annuities payable by half-yearly instalments.

The next work in which a commutation table is found is William Morgan's *Treatise on Assurances*, 1779. In this work the values of $\frac{l_x}{l_1}v^{x-1}$ are tabulated, and not those of $l_x v^x$; but, as above mentioned, the properties of the table are not altered by the change. Morgan gives the table as furnishing a convenient means of checking the correctness of the values of annuities found by the ordinary process. It may be assumed that he was aware that the table might be used for the direct calculation of annuities; but he appears to have been ignorant of its other uses.

The first author who fully developed the powers of the table was John Nicholas Tetens, a native of Schleswig, who in 1785, while professor of philosophy and mathematics at Kiel, published in the German language an *Introduction to the Calculation of Life Annuities and Assurances.* This work appears to have been quite unknown in England until Mr F. Hendriks gave, in the first number of the *Assurance Magazine*, pp. 1–20 (Sept. 1850), an account of it, with a translation of the passages describing the construction and use of the commutation table, and a sketch of the author's life and writings, to which we refer the reader who desires fuller information.

The use of the commutation table was independently developed in England—apparently between the years 1788 and 1811—by George Barrett, of Petworth, Sussex, who was the son of a yeoman farmer, and was himself a village schoolmaster, and afterwards farm steward or bailiff. In the form of table employed by him, the quantity tabulated is not $l_x v^x$, but $l_x(1+i)^{w-x}$, where w is the last age in the mortality table used. It has been usual to consider Barrett as the originator in this country of the method of calculating the values of annuities by means of a commutation table, and this method is accordingly sometimes called Barrett's method. (It is also called the commutation method and the columnar method.) Barrett's method of calculating annuities was explained by him to Francis Baily in the year 1811, and was first made known to the world in a paper written by the latter and read before the Royal Society in 1812.

By what has been universally considered an unfortunate error of judgment, this paper was not recommended by the council of the Royal Society to be printed, but it was given by Baily as an appendix to the second issue (in 1813) of his work on life annuities and assurances. Barrett had calculated extensive tables, and with Baily's aid attempted to get them published by subscription, but without success; and the only printed tables calculated according to his manner, besides the specimen tables given by Baily, are the tables contained in Babbage's *Comparative View of the various Institutions for the Assurance of Lives*, 1826. It may be mentioned here that Tetens also gave only a specimen table, apparently not imagining that persons using his work would find it extremely useful to have a series of commutation tables, calculated and printed ready for use.

In the year 1825 Griffith Davies published his *Tables of Life Contingencies*, a work which contains, among other tables, two arranged on the plan we have above explained, the idea of them having been confessedly derived from Baily's explanation of Barrett's tables. The method was, however, improved and extended by the addition of the columns (M and R) for finding the values of assurances. Davies's treatise on annuities, as issued by his executors in 1855, with the explanation that it is an uncompleted work, but that the completed portion had been in print since 1825, contains several other tables of the same kind. In the preface to this work it is stated that "the most important distinction between the two methods is, that Mr Davies's method is much simpler in principle than that of Mr Barrett, as the columnar numbers given by the latter must be considered more as the numerical results of algebraical expressions; whereas in Davies's arrangement it will be found, on reference to age 0, that the number in column D represents the number of children just born, and those opposite ages 1, 2, 3, 4, &c., to the end of life, the present sums which would be required for the payment of £1 to each survivor of such children at the end of 1, 2, 3, 4, &c., years to the extremity of life; and the sum thereof inserted in column N, opposite age 0, represents the present fund required to provide the payment of annuities of £1 each for life to all the children given in column D at age 0; and from this method very considerable amount of labour is avoided by multiplying the number living at each age by a fraction less than a unit; but by Barrett's method, the number living at each age has to be multiplied by the amount of £1 improved for as many years as are equal to the difference between that age and the greatest tabular duration, as already stated, which makes each product a large multiple of the number living." This passage, we are informed, correctly represents Mr Davies's own views on the subject. It may be noticed that Davies does not employ the notation used above, D_x, N_x, &c., but omits the subscript x. Thus, instead of the formula $\frac{N_{x+n}}{N_{x-1}-N_{x+n-1}}$ he would write $\frac{{}^{n}N}{N_1-{}^{n}N_1}$.

In some respects this notation is perhaps preferable to that now used, as it is certainly better, when there is no risk of confusion, to omit the subscript x. But Davies's notation cannot be adopted without alteration, as N_1 might be mistaken for the number in the column N opposite the age 1. We may, however, consistently with the principles of the notation adopted by the Institute of Actuaries, write the formula $\frac{{}^{n}N}{{}^{-1}N-{}^{n-1}N}$. The notation at present commonly used is due to David Jones, whose work (mentioned below) was the first that contained an extensive series of commutation tables.

On a general review of the whole evidence, we cannot help thinking that Barrett's merits in the matter have been somewhat exaggerated. The first idea of a commutation table was not due to him, but (leaving Tetens out of view) to Dale and Morgan; and it is certain that he was familiar with the latter's treatise. The change he introduced into the arrangement of the table, namely, multiplying by a power of $(1+i)$ instead of by a power of v, is the reverse of an improvement; and accordingly, his form of table has never been in practical use by any person but himself, excepting only Babbage. It is, of course, not to be denied that great credit is due to him as a self-educated man, for perceiving more clearly than his predecessors the great usefulness of the commutation table; but in our opinion he does not stand sufficiently out from those who preceded and followed him, to justify the attempt to attach his name to the columnar method of calculating the values of annuities and assurances. Those who desire to obtain further information on the matter, and to learn the views of other writers, can refer to the appendix to Baily's *Life Annuities and Assurances*, De Morgan's paper "On the Calculation of Single Life Contingencies," *Assurance Magazine*, xii. 348–9; Gray's *Tables and Formulæ*, chap. viii.; the preface to Davies's *Treatise on Annuities*; also Hendriks's papers in the *Assurance Magazine*, No. 1, p. 1, and No. 2, p. 12; and in particular De Morgan's "Account of a Correspondence between Mr George Barrett and Mr Francis Baily," in the *Assurance Magazine*, vol. iv. p. 185.

The principal D and N tables published in this country are contained in the following works:—

David Jones, *Value of Annuities and Reversionary Payments*, issued in parts by the Useful Knowledge Society, completed in 1843, which gives for the Northampton Table, 3 per cent. interest, columns D, N, S, M, R; Carlisle Table, interest 3, 3½, 4, 4½, 5, 6, columns D, N, S, M, R; and interest 7, 8, 9, 10, columns D, N, S. Volume ii. contains D and N tables for all combinations of two joint lives, according to the Northampton Table, 3 per cent., and the Carlisle, 3, 3½, 4, 4½, 5, 6 per cent.

Jenkin Jones, *New Rate of Mortality*, 1843, Seventeen Offices' Experience, 2½, 3, 3½ per cent., columns D, N, S, M, R.

G. Davies, *Treatise on Annuities*, 1825 (issued 1855). Equitable Experience, 2½, 3, 3½, 4, 4½, 5, 6 per cent., columns D, N, S, M, R; 7, 8 per cent., columns D, N; also three tables relating to joint lives for the differences of age 19, 20, 21 years, and one relating to three joint lives of equal ages, all giving D and N columns at 3 per cent. interest: Northampton, 3 per cent., columns D, N, S, M, R; 4 per cent., columns D, N; also tables for two joint lives similar to those above mentioned.

David Chisholm, *Commutation Tables*, 1858; Carlisle, 3, 3½, 4, 5, 6 per cent., columns D, N, S, C, M, R; also columns D, N, for joint lives, and M, R, for survivorship assurances.

Neison's *Contributions to Vital Statistics*, 1857. Mortality of England and Wales (males), 3, 3½, 4, 4½, 5, 6, 7, 8, 9, 10 per cent., columns D and N, with logarithms; two joint lives, males, 7 per cent., columns D and N; also D and N columns relating to the mortality of master mariners, and to that among friendly societies, and in particular the Manchester Unity.

Jardine Henry, *Government Life Annuity Commutation Tables*, 1866 and 1873, single lives male and female, 0, 1, 2, 2½, 3, 3½, 4, 4½, 5, 5½, 6, 7, 8, 9, 10 per cent.

Institute of Actuaries Life Tables, 1872. New Experience (or Twenty Offices), males and females separately, H^M and H^F, 3, 3½, 4, 4½, 5, 6, columns D, N, S, M, R, also logarithms; and similar tables at 3, 3½, and 4 per cent. for the table $H^{M(5)}$.

R. P. Hardy, *Valuation Tables*, 1873, gives the same table at 4½ per cent. for $H^{M(5)}$.

The *Sixth Report of the Registrar-General*, 1844, contains the English Table (No. 1), 3 and 4 per cent., columns D, N, S, C, M, R, for males and females separately; also D_{xy}, N_{xy}, 3 and 4 per cent., for x male and y female; also five tables for joint lives, one male and one female, differences of ages −20, −10, 0, 10, 20.

The *Twelfth Report*, 1849, contains the English Table (No. 2), males, 3, 4, 5, per cent., columns D, N, S, C, M, R.

The *Twentieth Report*, 1857, contains the English Table (No. 2), females, 3 per cent., columns D, N, S, C, M, R.

The *English Life Table*, 1864, contains columns D, N, at 3, 3¼, 3⅓, 3½, 3¾, 4, 5, 6, 7, 8, 9, 10 per cent., also the logarithms; columns S, C, M, R, at 3, 4, 5 per cent.; special tables for half-yearly and quarterly payments, columns D, N, at 3 per cent.; joint lives at all combinations of ages, columns D, N, at 3 per cent., (1) male and female, (2) two males, (3) two females.

The explanations of the tables in the last four works are by Dr William Farr, F.R.S.

Very unfortunately, these tables are not all arranged upon the same principle, but those contained in the Reports of the Registrar-General, in the *English Life Table*, in Chisholm's and in Henry's tables, are so arranged that the column N is shifted down one year, so that in them the ratio $\frac{N_x}{D_x}$ gives, not the value of the ordinary annuity, but the value of the annuity increased by unity, or the annuity-due. It is very needful to bear this in mind for the prevention of error; and the existence of a difference of this kind is extremely perplexing. For information upon the subject of this confusing change, see De Morgan's paper "On the Forms under which Barrett's Method is represented, and on Changes of words and symbols," *Ass. Mag.*, x. 302.

All the preceding methods require a considerable amount of calculation in order to obtain the value of an annuity on a life of any particular age. We will now explain some methods of approximation, by means of which we can calculate with much less labour the value of an annuity at a single age, when we do not require a complete table of annuities. The following method was demonstrated by Mr Lubbock (afterwards Sir J. W. Lubbock) in a paper "On the Comparison of Various Tables of Annuities" in the *Cambridge Philosophical Transactions* for the year 1829. Instead of calculating the value of each payment of the annuity to be received at the ages $x+1$, $x+2$, ... to the extremity of life, it will be sufficient to calculate the values of the payments to be received at a series of equidistant ages, say at the ages $x+n$, $x+2n$, $x+3n$, ... Then, if V_m denote the payment to be received at the age $x+m$, and Δ_1, Δ_2, Δ_3, ... denote the leading differences of V_0, V_n, V_{2n}, V_{3n} . . . . . . the value of the annuity is approximately

$$n\left(V_0+V_n+V_{2n}+V_{3n}+\ldots\ldots\right)-\frac{n+1}{2}+\frac{n^2-1}{12n}\Delta_1$$
$$-\frac{n^2-1}{24n}\Delta_2+\frac{(n^2-1)(19n^2-1)}{720n^3}\Delta_3-\frac{(n^2-1)(9n^2-1)}{480n^3}\Delta_4.$$

Here $V_0=1$, $V_n=\frac{l_{x+n}}{l_x}v^n$, $V_{2n}=\frac{l_{x+2n}}{l_x}v^{2n}$, &c.

As an example, we will apply this formula to calculate the value of an annuity on a nominee of 40, according to the English Table, No. 3, Males, at 3 per cent. interest.

First, taking $n=7$, we find

V_0 = 1·0000					
	− ·2654				
V_7 = ·7346		+ ·0521			
	·2133		− ·0115		
V_{14} = ·5213		·0406		+ ·0029	
	·1727		·0086		
V_{21} = ·3486		·0320			
	·1407				
V_{28} = ·2079					
V_{35} = ·0990					
V_{42} = ·0318					
V_{49} = ·0055					
V_{56} = ·0004					
Sum = 2·9491					

Hence $\Delta_1=-\cdot2654$, $\Delta_2=\cdot0521$, $\Delta_3=-\cdot0115$, $\Delta_4=\cdot0029$; and the value of the annuity is approximately

$$=7+2\cdot9491-4-\frac{4}{7}\times\cdot2654-\frac{2}{7}\times\cdot0521-\cdot1808\times\cdot0115-\cdot1283\times\cdot0029.$$

$$\begin{aligned}&=20\cdot6437-4\cdot0000\\&\qquad\;-\cdot1517\\&\qquad\;-\cdot0149\\&\qquad\;-\cdot0021\\&\qquad\;-\cdot0004\\&=20\cdot6437-4\cdot1691\\&=16\cdot4746.\end{aligned}$$

Next, taking $n=11$, we have

V_0 = 1·0000					
	− ·3924				
V_{11} = ·6076		+ ·1115			
	·2809		− ·0310		
V_{22} = ·3267		·0805		+ ·0453	
	·2004		+ ·0143		
V_{33} = ·1263		·0948			
	·1056				
V_{44} = ·0207					
V_{55} = ·0006					
2·0819					

Hence, the value of the annuity is approximately

$$=11\times2\cdot0819-6-\frac{10}{11}\times\cdot3924-\frac{5}{11}\times\cdot1115-\cdot2878\times\cdot0310-\cdot2044\times\cdot0453$$

$$\begin{aligned}&=22\cdot9009-6\cdot0000\\&\qquad\;-\cdot3567\\&\qquad\;-\cdot0507\\&\qquad\;-\cdot0089\\&\qquad\;-\cdot0093\\&=22\cdot9009-6\cdot4256\\&=16\cdot4753.\end{aligned}$$

The value of the annuity calculated in the ordinary way is, as we have seen (page 80), 16·4744.

An improved form of this method was given by Mr W. S. B. Woolhouse in the *Ass. Mag.*, xi. 321. In order to explain this, we must introduce the reader to a term which is of recent origin, but which the application of improved mathematical methods to the science of life contingencies has rendered of great importance—*the force of mortality* at a given age. This may be defined as the proportion of the persons of that age who would die in the course of a year, if the intensity of the mortality remained constant for a year, and the number of persons under observation also remained constant, the places of those who die being constantly replaced by fresh lives. More briefly, it is the instantaneous rate of mortality. A very full explanation of this term is given by Mr W. M. Makeham, in his paper "On the Law of Mortality," *Ass. Mag.*, xiii. 325. The value of the function can be approximately found by dividing the number of persons who die in a year by the number alive in the middle of the year. Thus, if l_x denote the number of persons living at the age x, d_x the number dying between the ages x and $x+1$, and d_{x-1} the number dying between the ages $x-1$ and x, then the number dying between the ages $x-\frac{1}{2}$ and $x+\frac{1}{2}$ will be approximately $\frac{d_{x-1}+d_x}{2}$, and the force of mortality is approximately $\frac{d_{x-1}+d_x}{2l_x}$. Thus, in the English Table, No. 3, Males, the value of the force of mortality at age 40 is $\frac{3465+3529}{544146}$ $=\cdot012853$.

This quantity is usually denoted by the Greek letter μ, while δ is used to denote the quantity $\log_e(1+i)$, which Woolhouse has called the *force of discount*. This being premised, Woolhouse's formula for the approximate value of an annuity is

$$n(V_n+V_{2n}+V_{3n}+\ .\ .\ .\ )+\frac{n-1}{2}-\frac{n^2-1}{12}(\mu+\delta),$$

where it will be noticed that, since $V_0=1$, the two first terms are exactly equal in value to those in Lubbock's formula.

Taking the same example as above, we have seen that

$$\begin{aligned}\mu_{40}&=\cdot012853\\ \text{also}\qquad \delta&=\cdot029558\\ \therefore\qquad \mu_{40}+\delta&=\cdot042411\end{aligned}$$

Making $n=7$, we have the value of the annuity

$$\begin{aligned}&=16\cdot6437-4\times\cdot042411\\&=16\cdot6437-\cdot169644\\&=16\cdot4741.\end{aligned}$$

Making $n=11$, we have the value

$$\begin{aligned}&=16\cdot9009-10\times\cdot042411\\&=16\cdot9009-\cdot4241\\&=16\cdot4768.\end{aligned}$$

Comparing the two processes, we see that when we have the values of μ and δ already computed, Woolhouse's is decidedly the shorter. On the other hand, it is easy to see that Lubbock's formula applies, not only to annuities, but to other benefits; and that it will be applicable to find the values of such quantities as contingent annuities, the values of which cannot be found exactly except by a very long series of calculations. (See Davies, p. 354.) The reader who refers to Lubbock's paper (which is reprinted in the *Ass. Mag.*, v. 277), or to the short account of it given in the *Treatise on Probability*, issued by the Useful Knowledge Society, and often bound up with D. Jones's work on annuities, will see that the terms involving Δ_2, Δ_3, Δ_4 are not given there; and it may assist the student who is desirous of working out the formula fully, to be referred to De Morgan's expansion of $\frac{x}{(1+x)^z-1}$, *Diff. Calc.*, p. 314, § 184. Lubbock not only considered it unnecessary to calculate the terms involving Δ_2, Δ_3, &c. but thought that the value of the term containing Δ_1, as calculated for one mortality table, might be used without material error in finding the values of annuities by other tables. The above examples show that the formula, as now completed, is capable of giving the values of annuities (and of course of other quantities) with very great accuracy.

So long as we consider the annuity to be payable yearly, no allowance being made for the time which elapses between the death of the nominee and the last previous payment of the annuity, it is, as we have seen, a very simple problem to calculate its value. But in practice annuities are generally payable by half-yearly instalments, and it is the custom to pay a proportionate part of the annuity for the odd time that elapses between the last half-yearly payment and the death of the nominee; and the value found by the methods described above therefore require to be corrected before they are strictly applicable in practice. Approximate values of the necessary corrections are very easily found; but the strict investigation of their correct values is a problem requiring a considerable knowledge of the higher mathematics, and it would be quite beyond our present purpose to consider it.

When an annuity is payable half-yearly, the common rule for finding its value is to add ·25, or a quarter of a year's purchase, to the value of the annuity payable yearly. When it is payable quarterly, ·375 is added; and when by instalments at n equal periods throughout the year (or by $\frac{1}{n}$-thly instalments), the addition is $\frac{n-1}{2n}$. The values thus found are sufficiently correct for most purposes. More correct methods of finding the values of annuities payable half-yearly, quarterly, &c., are investigated in papers in the *Assurance Magazine*, by Woolhouse, xi. 327, and by Sprague, xiii. 188, 201, 305. Some authors have assumed that when an annuity is payable half-yearly, interest is also convertible half-yearly, overlooking the circumstance that the true rate of interest is thereby changed, as we have explained in the earlier part of this article. In fact, as we showed, 5 per cent. interest convertible half-yearly is equivalent to a true rate of interest, £5, 1s. 3d. per cent. If, then, we have found the value of an annuity when payable yearly at 5 per cent. interest, and require, perhaps, in the course of the same investigation, the value of an annuity payable half-yearly, it is clear that that value should be computed, not at £5, 1s. 3d. per cent. interest, but at 5 per cent.; or if we prefer the rate £5, 1s. 3d., then the value of the annuity payable yearly should also be calculated at that rate.

The approximate value of an annuity payable up to the day of the nominee's death, or of a "complete" annuity, as it is now usually called, is found in the case of annuities payable yearly by adding to the value of the ordinary annuity the value of $\frac{1}{2}$, payable at the instant of the nominee's death; in the case of half-yearly annuities, by adding the value of $\frac{1}{4}$; and in the case of quarterly annuities, the value of $\frac{1}{8}$, similarly payable. The more exact value of the correction is investigated by Sprague, *Ass. Mag.*, xiii. 358.

The previous remarks refer almost exclusively to annuities which depend on the continuance of one life, or to "single life annuities," as they are commonly called. But an annuity may depend on the continuance of two or three or more lives. It may continue so long as both of two nominees are alive, in which case it is called an annuity on the joint lives; or it may continue as long as either of them is alive, in which case it is called an annuity on the last survivor. Again, if it depends on the existence of three nominees, it may either continue so long only as they are all three alive, when it is called an annuity on the joint lives; or so long as any two of them continue alive, when it is called an annuity on the last two survivors; or so long as any one of them is alive, when it is called an annuity on the last survivor. In addition to these, we have "reversionary" annuities, which are to commence on the failure of an assigned life, and continue payable for the life of a specified nominee; or, more generally, to commence on the failure of a given status, or combination of lives, and continue payable during the existence of another status. There are also "contingent" annuities, which depend on the order in which the lives involved fail. Thus, we may have an annuity on the life of x, to commence on the death of y, provided that take place during the life of z, and not otherwise, and to continue payable during the remainder of the life of x. Reversionary annuities are of considerable practical importance, but contingent annuities are rarely met with. Lastly, we may mention annuities on successive lives. These are of importance in the calculation of the values of advowsons, and of fines on copyhold property. It does not fall within the scope of this article to treat at any length of annuities on more than one life, and we must refer the reader who wishes for further information with regard to them to the works of Baily, Davies, and David Jones, already mentioned, and Milne's *Treatise on the Valuation of Annuities and Assurances*, 1815.

The student who wishes to pursue the subject more thoroughly, and to become acquainted with all the improvements in the theory of annuities that have been introduced of late years, should carefully study the various articles contributed to the *Journal of the Institute of Actuaries*, particularly those of Woolhouse and Makeham. The Institute was founded in the year 1848, the first sessional meeting being held in January 1849. Its establishment has contributed in various ways to promote the study of the theory of life contingencies. Among these may be specified the following:—Before it was formed, students of the subject worked for the most part alone, and without any concert; and when any person had made an improvement in the theory, it had little chance of becoming publicly known unless he wrote a formal treatise on the whole subject. But the formation of the Institute led to much greater interchange of opinion among actuaries, and afforded them a ready means of making known to their professional associates any improvements, real or supposed, that they thought they had made. Again, the discussions which follow the reading of papers before the Institute have often served, first, to bring out into bold relief differences of opinion that were previously unsuspected, and afterwards to soften down those differences,—to correct extreme opinions in every direction, and to bring about a greater agreement of opinion on many important subjects. In no way, probably, have the objects of the Institute been so effectually advanced as by the publication of its *Journal*. The first number of this work, which was originally called the *Assurance Magazine*, appeared in September 1850, and it has been continued quarterly down to the present time. It was originated by the public spirit of two well-known actuaries (Mr Charles Jellicoe and Mr Samuel Brown), and was carried on by them for two years, we believe, at a considerable loss. It was adopted as the organ of the Institute of Actuaries in the year 1852, and called the *Assurance Magazine and Journal of the Institute of Actuaries*, Mr Jellicoe continuing to be the editor,—a post he held until the year 1867, when he was succeeded by Mr Sprague. The name was again changed in 1866, the words "*Assurance Magazine*" being dropped; but in the following year it was considered desirable to resume these, for the purpose of showing the continuity of the publication, and it is now called the *Journal of the Institute of Actuaries and Assurance Magazine*. This work contains not only the papers read before the Institute (to which have been appended of late years short abstracts of the discussions on them), and many original papers which were unsuitable for reading, together with correspondence, but also reprints of many papers published elsewhere, which from various causes had become difficult of access to the ordinary reader, among which may be specified various papers which originally appeared in the *Philosophical Transactions*, the *Philosophical Magazine*, the *Mechanics' Magazine*, and the *Companion to the Almanac*; also translations of various papers from the French, German, and Danish. Among the useful objects which the continuous publication of the *Journal* of the Institute has served, we may specify in particular two:—that any supposed improvement in the theory was effectually submitted to the criticisms of the whole actuarial profession, and its real value speedily discovered; and that any real improvement, whether great or small, being placed on record, successive writers have been able, one after the other, to take it up and develop it, each commencing where the previous one had left off. The result has been, as stated above, that great advances have lately been made in the theory. It may be truly said that the recent advances and improvements in the theory of life contingencies have rendered all the existing text-books antiquated; and until a new one shall be produced, bringing the treatment of the subject down to the present time, a complete knowledge of it can only be gained by a diligent study of the *Journal of the Institute of Actuaries and Assurance Magazine.*

As intimated above, our remarks on annuities involving more than one life will be very brief. The methods employed for the calculation of single life annuities are easily extended to the case of joint life annuities. The fundamental equation

$$a = vp\,(1 + {}^1a)$$

is true of annuities on two, three, or any number of joint lives, if we consider p to denote the probability that they will all survive for one year; and ${}^1a$ the value of an annuity on the joint continuance of lives which are severally one year older than those on which the required annuity depends. Thus we have—x, y, z, being the ages of the nominees—

$$a_{xy} = v\,\frac{l_{x+1}}{l_x}\cdot\frac{l_{y+1}}{l_y}\,(1 + a_{x+1.y+1}),$$

$$= vp_xp_y\,(1 + {}^1a_{xy}),$$

$$\text{and } a_{xyz} = vp_xp_yp_z\,(1 + {}^1a_{xyz}).$$

The columnar method of calculating annuities admits also of being extended to annuities on joint lives. In the extensive tables contained in D. Jones's work,

$\mathrm{D}_{xy} = l_xl_yv^y$, y being the older of the two ages,
and $\mathrm{N}_{xy} = {}^1\mathrm{D}_{xy} + {}^2\mathrm{D}_{xy} + {}^3\mathrm{D}_{xy} + \ldots\ldots,$

where ${}^n\mathrm{D}_{xy}$ is used to denote $\mathrm{D}_{x+n.y+n}$.

An improved form of the table was suggested by De Morgan, according to which we should have $\mathrm{D}_{xy} = l_xl_yv^{\frac{x+y}{2}}$ This would simplify the formulas for the values of contingent annuities, but no tables have as yet been published calculated on this principle. The same method might be extended to three lives, in which case the most advantageous form would be $\mathrm{D}_{xyz} = l_xl_yl_zv^{\frac{x+y+z}{3}}$; but the extent of the tables when three lives are involved renders it extremely improbable that such will ever be published. The practical construction of a D and N table for joint lives has been considered by Gray, *Tables and Formulæ*, pp. 122–137, and *Ass. Mag.*, xviii. 26. Mr Jardine Henry has described in the *Ass. Mag.*, xiv. 212, a mechanical method of computing the values of $\mathrm{D}_{xy} = l_xl_yv^y$, by means of which he has calculated the values in his extensive tables mentioned above.

The values of annuities on the last survivor of two or more lives cannot be calculated by the ordinary methods that apply to annuities on joint lives; thus, for example, the equation $a = vp\,(1 + {}^1a)$ does not hold good with regard to them. Their values must be found from those of joint life annuities by means of the following formulas:—

An annuity on the last survivor of two lives, x and y, $\quad a_{\overline{xy}} = a_x + a_y - a_{xy}$

An annuity on the last survivor of three lives, x, y, and z, $\quad a_{\overline{xyz}} = a_x + a_y + a_z - a_{yz} - a_{zx} - a_{xy} + a_{xyz}$

An annuity on the last two survivers of the three lives, x, y, z, $\quad a_{\overline{xyz}}{}^2 = a_{yz} + a_{zx} + a_{xy} - 2a_{xyz}$

If we have the values of annuities on the last survivor of two lives tabulated, as is the case in the *Institute of Actuaries Life Tables*, we may find the value of an annuity on the last of three lives by means of the formula $a_{\overline{xyz}} = a_{\overline{xz}} + a_{\overline{yz}} - a_{\overline{wz}}$, where w is found by means of the relation $a_w = a_{xy}$; see *Ass. Mag.*, xvii. 266, 379.

The methods of approximation given by Lubbock and Woolhouse also apply to the calculation of annuities on the joint existence of any number of lives; see the latter's explanation of his method, *Ass. Mag.*, xi. 322, and for an illustration of its application to complicated cases, xvii. 267. They may also be applied to find the value of an annuity on the last survivor of any number of lives; see *Ass. Mag.*, xvi. 375.

The formula usually given for the value of a reversionary annuity on the life of x to commence on the death of y is $a_x - a_{xy}$. But this is not sufficiently correct, being deduced from suppositions that do not prevail in practice. It assumes the first yearly payment of the annuity to be made at the end of the year in which y dies, and the last at the end of the year before that in which x dies; whereas in practice the annuity runs from the death of y, the first yearly payment being made one year after such death, and a proportionate part being paid up to the date of x's death. A more correct formula, as given by Sprague (*Ass. Mag.*, xv. 126), is $\frac{a_x - a_{xy}}{\sqrt{1+i}}$. If the annuity is payable half-yearly, the value will be approximately $(a_x - a_{xy})\,\frac{1 + (1+i)^{-\frac{1}{2}}}{2}$; and if quarterly, $(a_x - a_{xy})\,\frac{i}{(1+i)^{\frac{1}{4}} - 1}$. In practice, it is often sufficient to deduct half a year's interest from the value found by the formula $a_x - a_{xy}$, when the annuity is payable yearly, a quarter of a year's interest when it is payable half-yearly, and an eighth of a year's interest when quarterly.

In dealing with annuities in which three lives are involved, we are met by the difficulty that no tables exist in which the values of such annuities are given to the extent required in practice. Such tables as those computed for the Carlisle 3 per cent. table by Herschel Filipowski are of too limited extent to be of any practical utility; for the values being given only for certain ages differing by multiples of five years, a considerable amount of labour is required to deduce the values for other ages. When, therefore, we desire to find the value of an annuity on the joint lives of say x, y, and z, it is usual to take the two oldest of the lives, say x and y, and find the value of a_{xy}, then to look in the table of single life annuities for the annuity which is nearest in value to this,—a_w suppose,—and lastly, to find the value of a_{wz}, and use it as an approximation to that of a_{xyz}. De Morgan, in a paper written for the *Philosophical Magazine* for November 1839, and reprinted in the *Ass. Mag.*, x. 27, proved that the value of a_{xyz} thus found would be strictly accurate, if the mortality followed the law known as Gompertz's; that is to say, if the number of persons living according to the mortality table at any age, x, could be represented by means of the formula dg^{q^x}. Gompertz proved, in the *Philosophical Transactions* for 1825, that by giving suitable values to the constants, the above formula might be made to represent correctly the number living during a considerable portion of life, say from age 10 to 60; but in order to represent by the same formula the numbers living at higher ages, it is necessary to give fresh values to the constants, and the discontinuity thence resulting has always been a fatal obstacle to the practical use of the formula. It has, however, from its theoretical interest, attracted a great deal of attention from actuaries; and numerous papers on the subject will be found in the *Assurance Magazine*. A claim to the independent (if not prior) discovery of the formula has been put forward by Mr T. R. Edmonds; but this claim, respecting which many communicatious will be found in the *Assurance Magazine*, is generally repudiated by competent judges. De Morgan further showed (*Ass. Mag.*, viii. 181) that if the above property holds good, or $a_{xyz} = a_{wz}$, then the mortality must follow Gompertz's law; and Woolhouse gave independently a simple algebraical demonstration of the same property, x. 121. Makeham removed the above mentioned objection to Gompertz's formula by introducing another factor, and showed (*Ass. Mag.*, xii. 315) that the formula $dg^{q^x}s^x$ will correctly represent the number living at any age x from about the age of 15 upwards to the extremity of life, and this formula has been found very serviceable for certain purposes.

The fact that Gompertz's law does not correctly represent the mortality throughout the whole of life, proves that the above-described practical method of finding the value of an annuity on three joint lives is accurate only in certain cases. Makeham has shown (*Ass. Mag.*, ix. 361, and xiii. 355) that when the mortality follows the law indicated by his modification of Gompertz's formula, the value of an annuity on two, three, or any number of joint lives, can be readily found by means of tables of very moderate extent. Thus the value of an annuity on any two joint lives can be deduced from the value of an annuity at the same rate of interest on two joint lives of equal ages; the value of an annuity on any three joint lives, by means of a table of the values of annuities on three joint lives of equal ages; and so on; and Woolhouse has shown (vol. xv. p. 401) how the values of annuities on any number of joint lives, at any required rate of interest, can be found by means of tables of the values of annuities on a single life at various rates of interest. These methods, we believe, have not hitherto been practically employed to any extent by actuaries, and it would perhaps be premature to say which of them is preferable.

As the reader will have observed, neither Gompertz's nor Makeham's formula represents correctly the rate of mortality for very young ages. Various formulas have been given which are capable of representing with sufficient accuracy the number living at any age from birth to extreme old age, but they are all so complicated that they are of little more than theoretical interest. They are, however, likely to prove of increasing value in the problem of adjusting (or graduating) a table of mortality deduced from observations,—an important subject, which does not fall within the scope of this article. We may mention in particular those given by Lazarus in his *Mortalitätsverhältnisse und ihre Ursache* (*Rates of Mortality and their Causes*), 1867, of which a translation is given by Sprague in the eighteenth volume of the *Assurance Magazine*, namely, $CK^{q^x}h^xH^{p^x}$, and by Gompertz (see *Ass. Mag.*, xvi. 329),

$$l_x = \text{const. } A^{r^x}B^{f^x \cdot x}C^{q^x}D^{P}, \text{ where } P = \theta\omega^{\pi^x(x-n)}.$$

If l_x represents the number living at any age in the mortality table, the force of mortality, or the instantaneous rate of mortality, mentioned above (see p. 83), is equal to $-\frac{d}{dx}\log_e l_x$ Hence, in Gompertz's original law the force of mortality at any age x is proportional to q^x, or is equal to aq^x, where a is a constant; in Makeham's law the force of mortality is equal to $aq^x + b$, where a and b are constants; and in Lazarus's law the force of mortality is equal to $aq^x + b + cp^x$, where a, b, and c are constants, or to $a\epsilon^{-mx} + b + c\epsilon^{nx}$ Dr Thiele has shown (see *Ass. Mag.*, xvi. 313) how to graduate a mortality table, by assuming the formula for the force of mortality, $a_1\epsilon^{-b_1x} + a_2\epsilon^{-\frac{1}{2}b_2^2(x-c)^2} + a_3\epsilon^{b_3x}$, and Makeham has explained (*Ass. Mag.*, xvi. 344) a very convenient practical method for adjustment, which results in assuming that the number living at any age x can be accurately represented by the sum of three terms of the form $dg^{q^x}s^x$.

The employment of formulas such as those given in the last paragraph, and the application of the differential calculus to the theory of life contingencies, have naturally led to an improvement in the theory which is probably destined to become of very great importance—we refer to the introduction of the idea of "continuous" annuities and assurances. If the intervals at which an annuity is payable are supposed to become more and more frequent, until we come to the limit when each payment of the annuity is made momently as it accrues, the annuity is called continuous. Strictly speaking, of course, this is an impossible supposition as regards actual practice; but if an annuity were payable by daily instalments, its value would not differ appreciably from that of a continuous annuity, and if the annuity be paid weekly, the difference will be so small that it may be always safely neglected. The theory of continuous annuities has been fully developed by Woolhouse (*Ass. Mag.*, xv. 95). Assuming the number living in the mortality table at any age x to be represented by l_x, the value of a continuous annuity on a nominee of the age x is $\frac{1}{l_x}\int_x^\infty l_x v^x dx = \frac{1}{l_x}\int_x^\infty l_x \epsilon^{-\delta x} dx$, putting $\delta = \log_\epsilon(1+i)$. From the nature of the case, l_x must be a function that is never negative for positive values of x and as x becomes larger, l_x must continually diminish, and must vanish when x becomes infinite. It will be noticed here that the superior limit of the integral is ∞. This is necessary if l_x is a continuous mathematical function; for in that case, however large x be taken, l_x will never become absolutely zero. Makeham has shown (*Ass. Mag.*, xvii. 305) that when the number living, l_x, can be correctly represented by the formula $cg^{q^x}e^{-ax}$, the value of a continuous annuity is equal to $\frac{1}{\log q} \cdot \frac{1}{10^{-10^z} \cdot \epsilon^{-nz}} \int_z^\infty 10^{-10^z} \cdot \epsilon^{-nz} \cdot dz$, where $n = \frac{\alpha + \delta}{\log_{10} q}$, and $z = x \log_{10} q + \log_{10}^2 \frac{1}{g}$; and he has given (pp. 312–327) a table, by means of which the value of the annuity can be found when the values of n and z are known. This table requires a double interpolation, and is therefore rather troublesome to use. Mr Emory M'Clintock has shown in the eighteenth volume of the *Assurance Magazine*, how the value of an annuity may be found by means of the ordinary tables of the gamma-function. As Lazarus has pointed out in his above-mentioned paper, when mortality tables are given in the ordinary form, it is difficult to compare them and define precisely their differences; but if they can be accurately represented by a formula containing only a few constants, it becomes easy to show wherein one table differs from another; and the methods of Makeham and M'Clintock enable us to compare the values of annuities, for any ages desired, according to different tables as determined by such constants, without the labour of computing the mortality tables in the usual form. They can therefore scarcely fail to grow in popularity as they become better known.

The principal application of the theory of life annuities is found in life insurance. (See INSURANCE.) At the present time there are upwards of one hundred companies of various kinds transacting the business of life insurance in the United Kingdom. It is only since the passing of the Life Assurance Companies Act, 1870, that it has been possible to form an accurate estimate of the extent of the business transacted by these companies; but, from the returns made under that Act, it appears that the total assets of the companies amount to about £110,000,000, which are invested so as to produce an annual income of about £4,000,000, and that the total premiums received annually for insurance amount to about £10,000,000. There is no means at present of saying exactly what is the total sum assured; but it is probably about £330 000,000, the average premium for insurance being about 3 per cent. per annum. The actual transactions at the present time in the purchase and grant of immediate annuities, although small in comparison with the life insurance transactions, are yet of considerable amount. It appears from the returns made under the above-mentioned Act, that upwards of £250,000 is annually paid to insurance companies for the purchase of annuities, and that the aggregate amount of their liabilities under that head is nearly £420,000 a year The Government competes with the companies in the grant of annuities; and although its terms are on the whole very much less favourable than the companies', still in consequence of the greater security offered, the business transacted by the Government is much in excess of that transacted by the whole of the insurance companies. It appears from recent returns (see *Ass. Mag*, xv 23), that the life annuities annually paid by the National Debt Office amount to about £1,000,000, and that about £600,000 is on the average annually invested with the Government for the purchase of fresh annuities. The purchase and grant of life annuities have been carried on to a very considerable extent, apparently at all times. We learn from De Wit's above-mentioned report, that the Governments of Holland and West Friesland had granted annuities systematically for one hundred and fifty years before any correct estimate was formed of the value of a life annuity The British Government has at various times granted life annuities, more especially on the Tontine principle, for the purpose of raising money when it was difficult to obtain the sums required for the public service by the ordinary methods. Various local bodies have at different times raised money on the security of the local rates in consideration of the grant of life annuities; and, at the present time, the Manchester Corporation grants annuities on favourable terms for the purpose of obtaining funds to defray the expense of the waterworks belonging to the city. During the existence of the usury laws, it was very common for persons borrowing money upon the very best security to grant annuities upon their lives in consideration of a present advance. Thus, for example, if a country gentleman of the age of 40 wished to borrow £10,000 upon a landed estate, the law forbade him to pay, or the lender to receive, more than 5 per cent. interest, say £500 a year, but the law did not forbid his granting an annuity of £1000 for his life, secured upon the estate. Speaking roughly, an annual payment of £300 would be required to insure £10,000 upon the borrower's life, and the annuity would therefore return the lender about 7 per cent. interest, in addition to the premium on the insurance necessary to return his capital. In this way the law, which was intended as a protection to the borrower, to enable him to obtain a loan at a fixed moderate rate of interest, very often had the directly opposite effect of greatly increasing the cost of borrowing. The usury laws being now repealed, borrowers and lenders are left at full liberty to make such terms with each other as they may think best. (T. B. S.)

ANNUNCIATION, the announcement made by the angel Gabriel to the Virgin Mary of the incarnation of Christ (Luke i. 26–38). A festival commemorative of the annunciation is kept by the church on the 25th of March. The first authentic allusions to it are in a canon of the Council of Toledo (656 A.D.), and another of the Council of Trullo (692), forbidding the celebration of all festivals in Lent, excepting the Lord's day and the Feast of the Annunciation. An earlier origin has been claimed for it on the ground that it is mentioned in sermons of Athanasius and of Gregory Thaumaturgus, but both these documents are now admitted to be spurious.

ANODYNE (α privative, and ὀδύνη, pain), denotes etymologically anything which relieves pain. The common usage of the word restricts it, however, to medicines which lessen the sensibility of the brain or nervous system, without acting directly on the cause of pain The anodynes generally employed are opium, henbane, hemlock, tobacco, stramonium, and chloroform.

ANOINTING, the practice of pouring an aromatic oil upon the head or over the whole body, has been in use from the earliest times among Oriental nations, from whom it passed, chiefly in its ceremonial application, to the nations of the west. It served three distinct purposes, being regarded as a means of health and comfort, as a token of honour, or as a symbol of consecration. Reasoning from analogy, it seems probable that anointing was practised for sanative reasons before it became a religious ceremonial, but it is impossible to determine this with certainty. Its adoption as a sanative agent was dictated chiefly by the conditions of climate in the East. Used as it generally was in conjunction with the bath, it closed the pores, repressed undue perspiration, and so prevented loss of strength. It was also regarded as a protection against the heat of the sun, and the oil, being aromatic, counteracted disagreeable smells The anointing of the head as a token of honour paid to guests and strangers is mentioned in Scripture (Ps. xxiii. 5, Luke vii. 46), and was customary among the Egyptians (Wilkinson's *Ancient Egyptians*, ii. 213), the Greeks, and the Romans. Anointing as a symbol of consecration was practised among the Jews from the time of the exodus from Egypt, as part of the ceremonial investiture with the sacred offices of prophet (1 Kings xix. 16), priest (Exod. xxix. 7), and king (1 Sam. ix. 16). It does not seem to have been essential to the consecration of a prophet, and, as each individual holder of the office of priest or king was not anointed, it has been generally inferred that in these cases it was essential only at the consecration of a new line or dynasty. The titles *Messiah* and *Christ*, both meaning anointed, are applied to our Saviour as the anti-typical prophet, priest, and king. Anointing has passed from the Jewish into the Christian economy, and finds a place in the rites of baptism, confirmation, dedication of a church, &c., as these are administered in the Roman Catholic and Episcopalian communions. Its use at coronations symbolises the idea of monarchy as a mediate theocracy The practice of anointing the sick in the primitive church, and the dying in the Roman Catholic Church, will be found treated in the article EXTREME UNCTION.

ANOUKIS, or ANAKA, the name of an Egyptian goddess, one of the contemplar or companion goddesses of Khnum or Chnoumis. Her name meant "the Clasper" or "Embracer." She belonged to the "triad of Elephantine," formed of Khnum or Chnoumis, Sati or Satis —the Egyptian Hera or Juno, "the sunbeam"—and herself. As Sati personified the upper world or hemisphere, and wore the white crown upon her head, so Anoukis wore the red crown, emblem of the lower world or hemisphere. She personified Hestia or Vesta, and had the crown surmounted by a tiara of feathers, similar to those of the Pulusata, or supposed Pelasgi, and Tsakkaru, or Teucri, as if she had been a goddess of these nations. Some have compared her name to that of the Phœnician goddess *Onga*. It rarely appears in the texts and monuments, although it is occasionally seen. Statuettes of Anoukis are of the greatest rarity, if, indeed, they occur. —Champollion, *Panth. Egypt;* Wilkinson, *Mann. and Cust.*, v. p. 26, Rosellini, *Mon. d. Cult.*, ii., Letronne, *Recherches*, pp. 345–6.

ANQUETIL, LOUIS PIERRE, a French historian, was born at Paris, 21st Jan. 1723. He was for some time director of the academy at Rheims, and published in 1757 three volumes of a history of that city. In 1759 he was appointed prior of the abbey de la Roe, in Anjou, and soon after director of the college of Senlis. In 1766 he obtained the curacy or priory of Chateau-Renard, near Montargis, which he exchanged, at the commencement of the Revolution, for the curacy of La Villette, in the neighbourhood of Paris. During the reign of terror he was imprisoned at St Lazare. On the establishment of the National Institute he was elected a member of the second class, and was soon afterwards employed in the office of the minister for foreign affairs. He died on the 6th of September 1808. Anquetil left a very considerable number of historical works; but his style is censurable in many respects, and he appears to have been almost entirely destitute of the critical discernment and philosophical sagacity of a good historian. A list of his works is given in the *Biographie Universelle*.

ANQUETIL DU PERRON, ABRAHAM HYACINTHE, an eminent Oriental scholar, brother of the subject of the preceding article, was born at Paris 7th Dec. 1731. He was a distinguished student at the university of that city, and at first intended to enter the church; but his taste for Hebrew, Arabic, Persian, and other languages of the East, developed into a passion, and he discontinued his theological course to devote himself entirely to them. His diligent attendance at the Royal Library, and his ardour in the prosecution of his favourite studies, attracted the attention of the keeper of the manuscripts, the Abbé Sallier, whose influence procured for him a small salary as student of the Oriental languges. He had scarcely received this appointment, when, lighting on some manuscripts in the Zend, he formed the project of a voyage to India, with the view of discovering the works of Zoroaster. Seeing no other means of accomplishing his plan, he enlisted as a common soldier on the 7th of November 1754, in the Indian expedition which was about to start from the port of L'Orient. His friends procured his discharge, and the minister, affected by his romantic zeal for knowledge, granted him a free passage, a seat at the captain's table, and a salary, the amount of which was to be fixed by the governor of the French settlement in India. After a passage of nine months, Anquetil landed, on the 10th of August 1755, at Pondicherry. Here he remained a short time to master modern Persian, and then hastened to Chandernagore, to acquire Sanscrit. Just then war was declared between France and England; Chandernagore was taken; and Anquetil resolved to return to Pondicherry by land. The journey was one of a hundred days, and he had many adventures and suffered many hardships by the way. He found one of his brothers at Pondicherry, and embarked with him for Surat, but, with the view of exploring the country, he landed at Mahe, and proceeded on foot. At Surat he succeeded, by perseverance and address in his intercourse with the native priests, in acquiring a sufficient knowledge of the languages to enable him to translate the dictionary called the *Vedidad-Sade*, and some other works. Thence he proposed going to

Benares, to study the languages, antiquities, and sacred laws of the Hindus; but the capture of Pondicherry obliged him to quit India. Returning to Europe in an English vessel, he spent some time in London and Oxford, and then set out for France. He arrived in Paris in May 1762, without fortune or the desire of acquiring it, but esteeming himself rich in the possession of one hundred and eighty Oriental manuscripts, besides other curiosities. The Abbé Barthelemy procured for him a pension, with the appointment of interpreter of Oriental languages at the Royal Library. In 1763 he was elected an associate of the Academy of the Belles Letters; and began to arrange for the publication of the materials he had collected during his Eastern travels. In 1771 he published in three vols. 4to, the *Zend-Avesta*, containing collections from the sacred writings of the Persians, a life of Zoroaster, and fragments of works ascribed to that sage. The work was a very important accession to our stores of Oriental literature. Sir John Malcolm (*Hist. of Persia*, vol. i. p. 193, note) refers to the *Zend-Avesta* as the most authentic source of information on the religion and institutions of the great Persian legislator. In 1778 he published his *Législation Orientale*, in which he controverted the system of Montesquieu, and endeavoured to prove that the nature of Oriental despotism had been greatly misrepresented. His *Recherches Historiques et Géographiques sur l'Inde* appeared in 1786, and formed part of Thieffenthaler's *Geography of India*. The Revolution seems to have greatly affected him. During that period he abandoned society, and shut himself up in literary seclusion. In 1798 he published in 2 vols. 8vo, *L'Inde en Rapport avec l'Europe*, a work remarkable for its invectives against the English, and its numerous misrepresentations. In 1804 he published in 2 vols. 4to, a Latin translation from the Persian of the *Oupnek'hat* or *Upanischada, i.e.*, secrets which must not be revealed. It is a curious mixture of Latin, Greek, Persian, Arabic, and Sanscrit. (See *Ed. Rev.*, vol. i. pp. 412–421). On the reorganisation of the Institute, Anquetil was elected a member, but soon afterwards gave in his resignation. He died at Paris 17th January 1805. Besides the works named above, he was the author of several others on subjects connected with the history and antiquities of the East. See *Biographie Universelle; Monthly Review*, vol. lxi.; Lord Teignmouth's *Life of Sir William Jones*.

ANSBACH, or ANSPACH, originally ONOLZBACH, a town of Bavaria, capital of the circle of Middle Franconia, and formerly of the margraviate of Ansbach, situated on the Rezat, 25 miles S.W. of Nuremberg, and 90 N. of Munich. It is a pleasantly-built place, containing a castle, once the residence of the margraves, and still noted for the gardens that surround it; several churches, the finest of which are those dedicated to St John and St Gunibert; a gymnasium; and a picture gallery. The chief manufactures of Ansbach are woollen, cotton, and half-silk stuffs, earthenware, tobacco, cutlery, and playing cards. There is a considerable trade in grain, wool, and flax. In 1791 the last margrave of Ansbach sold his principality to Frédérick William II., king of Prussia; it was transferred by Napoleon to Bavaria in 1806, an act which was confirmed by the Congress of Vienna in 1815. Population of the town, 12,635.

ANSELM, Archbishop of Canterbury, was born in 1033, at or near Aosta, in Piedmont. His family was accounted noble, and was possessed of considerable property. Gundulph, his father, was by birth a Lombard, and seems to have been a man of harsh and violent temper; his mother, Ermenberga, was a prudent and virtuous woman, from whose careful religious training the young Anselm derived much benefit. At the early age of fifteen he desired to devote himself to the service of God by entering a convent, but he could not obtain his father's consent. Disappointment brought on an illness, on his recovery from which he seems for a time to have given up his studies, and to have plunged into the gay life of the world. During this time his mother died, and his father's harshness became unbearable. He left home, and with only one attendant crossed the Alps, and wandered through Burgundy and France. Attracted by the fame of his countryman, Lanfranc, then prior of Bec, he entered Normandy, and, after spending some time at Avranches, settled at the monastery of Bec. There, at the age of twenty-seven, he became a monk; three years later, when Lanfranc was promoted to the abbacy of Caen, he was elected prior. This office he held for fifteen years, and then, in 1078, on the death of Herluin, the warrior-monk who had founded the monastery, he was made abbot. Under his rule Bec became the first seat of learning in Europe, a result due not more to his intellectual powers than to the great moral influence of his noble character, and his loving, kindly discipline. It was during these quiet years at Bec that Anselm wrote his first philosophical and religious works, the dialogues on Truth and Freewill, and the two celebrated treatises, the *Monologion* and *Proslogion*. Meanwhile the convent had been growing in wealth, as well as in reputation, and, among other properties, had acquired considerable possessions in England. Anselm paid frequent visits to that country in connection with the convent lands, and by his mildness of temper and unswerving rectitude, so endeared himself to the English that he was looked upon and desired as the natural successor to Lanfranc, then archbishop of Canterbury. But on the death of that great man, the ruling sovereign, William Rufus, seized the possessions and revenues of the see, and made no new appointment. About four years after, in 1092, on the invitation of Hugh, earl of Chester, Anselm, with some reluctance, for he feared to be made archbishop, crossed to England. He was detained by business for nearly four months, and when about to return, was refused permission by the king. In the following year William fell ill, and thought his death was at hand. Eager to make atonement for his sin with regard to the archbishopric, he nominated Anselm to the vacant see, and, after a great struggle, compelled him to accept the pastoral staff of office. After obtaining dispensation from his duties in Normandy, Anselm was consecrated in 1093. He demanded of the king, as the conditions of his retaining office, that he should give up all the possessions of the see, accept his spiritual counsel, and acknowledge Urban as Pope, in opposition to the anti-pope, Clement. He only obtained a partial consent to the first of these, and the last involved him in a serious difficulty with the king. It was a rule of the church that the consecration of metropolitans could not be completed without their receiving from the hands of the Pope the *Pallium*, or robe. Anselm, accordingly, insisted that he must proceed to Rome to receive the pall. But William would not permit this; he had not acknowledged Urban, and he maintained his right to prevent any Pope being acknowledged by an English subject without his permission. A great council of churchmen and nobles, held to settle the matter, advised Anselm to submit to the king, but failed to overcome his mild and patient firmness. The matter was postponed, and William meanwhile privately sent messengers to Rome, who acknowledged Urban, and prevailed on him to send a legate to the king, bearing the archiepiscopal pall. A partial reconciliation was then effected, and the matter of the pall was compromised. It was not given by the king, but was laid on the altar at Canterbury, whence Anselm took it. Little more than a year after, fresh trouble arose with the king, and Anselm resolved to proceed to Rome and seek the counsel of his spiritual father.

With great difficulty he obtained a reluctant permission to leave, and in October 1097 he set out for Rome. William immediately seized on the revenues of the see, and retained them to his death. Anselm was received with high honour by Urban, and at a great council held at Bari, he was put forward to defend the Latin doctrine of the Holy Ghost against the objections of the Greek Church. But Urban was too politic to embroil himself with the king of England, and Anselm found that he could obtain no substantial result. He withdrew from Rome, and spent some time at the little village of Schlavia. Here he finished his treatise on the atonement, *Cur Deus homo*, and then retired to Lyons. In 1100 William was killed, and Henry, his successor, at once recalled Anselm. But Henry demanded that he should again receive from him in person investiture in his office of archbishop, thus making the dignity entirely dependent on the royal authority. Now, the Papal rule in the matter was plain; all homage and lay investiture were strictly prohibited. Anselm represented this to the king; but Henry would not relinquish a privilege possessed by his predecessors, and proposed that the matter should be laid before the Holy See. The answer of the Pope reaffirmed the law as to investiture. A second embassy was sent, with a similar result. Henry, however, remained firm, and at last, in 1103, Anselm and an envoy from the king set out for Rome. The Pope, Paschal, reaffirmed strongly the rule of investiture, and passed sentence of excommunication against all who had infringed the law, except Henry. Practically this left matters as they were, and Anselm, who had received a message forbidding him to return to England, unless on the king's terms, withdrew to Lyons, where he waited to see if Paschal would not take stronger measures. At last, in 1105, he resolved himself to excommunicate Henry. His intention was made known to the king through his sister, and it seriously alarmed him, for it was a critical period in his affairs. A meeting was arranged, and a reconciliation between them effected. In 1106 Anselm crossed to England, with power from the Pope to remove the sentence of excommunication from the illegally invested churchmen. In 1107 the long dispute as to investiture was finally ended by the king resigning his formal rights. The remaining two years of Anselm's life were spent in the duties of his archbishopric. He died 21st April 1109. His canonization appears to have taken place in 1494.

Anselm may, with some justice, be considered the first scholastic philosopher and theologian. His only great predecessor, Scotus Erigena, had more of the speculative and mystical element than is consistent with a schoolman; but in Anselm are found that recognition of the relation of reason to revealed truth, and that attempt to elaborate a rational system of faith, which form the special characteristics of scholastic thought. His constant endeavour is to render the contents of the Christian consciousness clear to reason, and to develop the intelligible truths interwoven with the Christian belief. The necessary preliminary for this is the possession of the Christian consciousness. "He who does not believe will not experience; and he who has not experienced will not understand." That faith must precede knowledge is reiterated by him. "Neque enim quæro intelligere ut credam, sed credo ut intelligam. Nam et hoc credo, quia, nisi credidero, non intelligam." "Christianus per fidem debet ad intellectum proficere, non per intellectum ad fidem accedere." "Rectus ordo exigit, ut profunda Christianæ fidei credamus, priusquam ea præsumamus ratione discutere." But after the faith is held fast, the attempt must be made to demonstrate by reason the truth of what we believe. It is wrong not to do so. "Negligentiæ mihi esse videtur, si, postquam confirmati sumus in fide, non studemus quod credimus, intelligere." To such an extent does he carry this demand for rational explanation that, at times, it seems as if he claimed for unassisted intelligence the power of penetrating even to the mysteries of the Christian faith. On the whole, however, the qualified statement is his real view; merely rational proofs are always, he affirms, to be tested by Scripture. (*Cur Deus homo*, i. 2 and 38; *De Fide Trin.* 2.)

The groundwork of his theory of knowledge is contained in the tract *De Veritate*, in which, from the consideration of truth as in knowledge, in willing, and in things, he rises to the affirmation of an absolute truth, in which all other truth participates. This absolute truth is God himself, who is therefore the ultimate ground or principle both of things and of thought. The notion of God comes thus into the foreground of the system; before all things it is necessary that it should be made clear to reason, that it should be demonstrated to have real existence. This demonstration is the substance of the *Monologion* and *Proslogion*. In the first of these the proof rests on the ordinary grounds of realism, and coincides to some extent with the earlier theory of Augustine, though it is carried out with singular boldness and fulness. Things, he says, are called good in a variety of ways and degrees; this would be impossible if there were not some absolute standard, some good in itself, in which all relative goods participate. Similarly with such predicates as great, just; they involve a certain greatness and justice. The very existence of things is impossible without some one Being, by whom they are. This absolute Being, this goodness, justice, greatness, is God. Anselm was not thoroughly satisfied with this reasoning; it started from *a posteriori* grounds, and contained several converging lines of proof. He desired to have some one short demonstration. Such a demonstration he presented in the *Proslogion*; it is his celebrated ontological proof. God is that being than whom none greater can be conceived. Now, if that than which nothing greater can be conceived existed only in the intellect, it would not be the absolutely greatest, for we could add to it existence in reality. It follows, then, that the being than whom nothing greater can be conceived, *i.e.*, God, necessarily has real existence. This proof has rarely seemed satisfactory. It was opposed at the time by the monk Gaunilo, in his *Liber pro Insipiente*, on the ground that we cannot pass from idea to reality. The same criticism is made by several of the later schoolmen, among others by Aquinas, and is in substance what Kant advances against all ontological proof. Anselm replied to the objections of Gaunilo in his *Liber Apologeticus*. The existence of God being thus held proved, he proceeds to state the rational grounds of the Christian doctrines of creation and of the Trinity. With reference to this last, he says we cannot know God from himself, but only after the analogy of his creatures; and the special analogy used is the self-consciousness of man, its peculiar double nature, with the necessary elements, memory and intelligence, representing the relation of the Father and the Son. The mutual love of these two, proceeding from the relation they hold to one another, symbolises the Holy Spirit. The further theological doctrines of man, original sin, free will, are developed, partly in the *Monologion*, partly in special treatises. Finally, in his greatest work, *Cur Deus homo*, he undertakes to make plain, even to infidels, the rational necessity of the Christian mystery of the atonement. The theory rests on three positions: that satisfaction is necessary on account of God's honour and justice; that such satisfaction can be given only by the peculiar personality of the God-man; that such satisfaction is really given by the voluntary death of this infinitely valuable person. The demonstration is, in brief, this. All the actions of men are due to the furtherance of God's glory; if, then, there be sin, *i.e.*, if God's honour be wounded, man of himself can give no satisfaction. But the justice of God demands satisfaction; and as an insult to infinite honour is in itself infinite, the satisfaction must be infinite, *i.e.*, it must outweigh all that is not God. Such a penalty can only be paid by God himself, and, as a penalty for man, must be paid under the form of man. Satisfaction is only possible through the God-man. Now this God-man, as sinless, is exempt from the punishment of sin; His passion is therefore voluntary, not given as due. The merit of it is therefore infinite; God's justice is thus appeased, and His mercy may extend to man. This theory has exercised immense influence on the form of church doctrine. It is certainly an advance on the older patristic theory, in so far as it substitutes for a contest between God and Satan, a contest between the goodness and justice of God; but it puts the whole relation on a merely legal footing, gives it no ethical bearing, and neglects altogether the consciousness of the individual to be redeemed. In this respect it contrasts unfavourably with the later theory of Abelard.

Anselm's speculations did not receive, in the Middle Ages, the respect and attention justly their due. This was perhaps owing to their unsystematic character, for they are generally tracts or dialogues on detached questions, not elaborate treatises like the great works of Albert, Aquinas, and Duns Scotus. They have, however, a freshness and philosophical vigour, which more than makes up for their want of system, and which raises them far above the level of most scholastic writings.

A full account of Anselm's life is given by Eadmer, *Vita Anselmi*. His works have been frequently published; the best editions are by Gerberon (containing the life, by Eadmer), Paris, 1675, 2nd ed. 1721; and in Migne, *Patrologiæ Cursus Completus*, vol. clv.

The *Cur Deus homo* has been frequently published in a separate form. The *Monologion* and *Proslogion* have been translated, with notes, by Bouchitté, *Le Rationalisme Chrétien*, Paris, 1842. In addition to the copious notices in general histories of theology and philosophy, the following works may be referred to:—Möhler, *Anselm*, translated into English, 1842; Franck, *Anselm von Canterbury*, 1842; Hasse, *Anselm von Canterbury*, I. "Leben," 1843, II. "Philosophie," 1852; Remusat, *Anselm de Cantorbéry*, 1855, 2d ed. 1868; R. W. Church, *St Anselm*, 1870.

ANSELM, of LAON, a famous theologian, was born of very humble parents at Laon before the middle of the 11th century. He is said to have studied under St Anselm at Bec. About 1076 he taught at Paris with great success, but not long afterwards removed to his native place, where his school for theology rapidly became the most famous in Europe. He died 1117. His greatest work was an interlinear gloss on the Scriptures, which has been frequently reprinted. Other commentaries apparently by him have been ascribed to various writers, principally to the great Anselm. A list of them, with notice of Anselm's life, is contained in the *Histoire Littéraire de la France*, x. 170–189.

ANSON, GEORGE, LORD, the famous circumnavigator, was born at Shuckborough Manor, Staffordshire, on the 22d of April 1697. He entered the navy at the age of fifteen. By the time he was twenty-one he had been promoted to the command of the "Weasel" sloop, and by 1724 to the command of the man-of-war "Scarborough." Between this year and 1735 he was engaged in active service, chiefly on the Carolina stations in America, and a town and county, named Ansonborough, in South Carolina, commemorate his residence there. He was recalled in 1739, on the outbreak of the Spanish war, and entrusted with the command of a squadron of eight vessels, equipped to annoy the Spaniards in the South Seas, and to co-operate with Admiral Vernon across the Isthmus of Darien. Anson sailed in September 1740; doubled Cape Horn in a dangerous season; lost most of his men by the scurvy, and with only one remaining ship, the "Centurion," crossed the Pacific Ocean. If no considerable national advantage resulted from this voyage, Commodore Anson made his own fortune, and enriched his surviving companions, by the capture of a rich galleon on her passage from Acapulco to Manilla. He was no less fortunate in escaping a French fleet, then cruising in the Channel, by sailing through it during a fog. Soon after his return, in 1744, he was appointed rear-admiral of the blue, and one of the lords of the Admiralty. In April 1745 he was made rear-admiral of the white, and the following year vice-admiral of the blue, when he was chosen member of parliament for the borough of Heydon. In 1747 he intercepted, off Cape Finisterre, a powerful fleet, bound from France to the East and West Indies, taking six men-of-war and four East Indiamen, not one of them escaping. The French admiral, Jonquiere, on presenting his sword to the conqueror, said, *Monsieur, vous avez vaincu l'Invincible, et la Gloire vous suit*—"Sir, you have conquered the Invincible, and Glory follows you," pointing to the ships named the "Invincible" and the "Glory," which he had taken. For his signal services he was created Baron Anson, of Soberton, in Hants, and vice-admiral of the red; and, on the death of Sir John Norris, vice-admiral of England. In 1748 he was made admiral of the blue. In 1757 he became first lord of the Admiralty, and in 1761 admiral of the fleet, in which rank he continued, with a very short interval, until his death; and the last service he performed was to convey Queen Charlotte to England. He died 6th June 1762. No book ever met with a more favourable reception than *Lord Anson's Voyage Round the World*, which, though printed under the name of his chaplain, was composed by Benjamin Robins under the inspection of, and from materials furnished by Lord Anson.

ANSTEY, CHRISTOPHER, poet, was son of the Rev. Christopher Anstey, rector of Brinkley, Cambridgeshire, where he was born in 1724–5. He was educated at Eton and King's college, Cambridge. He was originally designed for the church, but his degrees being withheld from him, he retired into privacy "upon a competent fortune." He was rusticated from the university. A speech made by him in one of the public schools upon some offence given by him, thus began, "Doctores sine doctrinâ, magistri artium sine artibus, et baccalaurei baculo potius quam lauro digni." The penalty was his rustication. He entered the army, and having married a daughter of Cabert of Allbury Hall, Herts, he obtained a seat in parliament for Hertford by his father-in-law's influence. One of the most glaring of current literary blunders is the common statement that the *New Bath Guide* of Christopher Anstey was in a great measure built on Smollett's novel of *Humphrey Clinker*. The facts are that the *New Bath Guide* was published in 1766, whilst *Humphrey Clinker* was not written until 1770, and was first published in 1771. It may be conceded that Sir Walter Scott holds the balance even in his verdict, as follows:—"But Anstey's diverting satire was but a slight sketch compared to the finished and elaborate manner in which Smollett has, in the first place, identified his characters, and then filled them with language, sentiments, and powers of observation in exact correspondence with their talents, temper, condition, and disposition" (*Works of Smollett*, Introduction). Perhaps "diverting" is a rather inadequate word, for there is depth of insight and weight of shrewd sense beneath the sparkle and the laughter of the *New Bath Guide*. The *Election Ball, in Poetical Letters from Mr Inkle at Bath to his Wife at Gloucester*, sustained the reputation won by the

Guide. It seems to us even more brilliant in its wit, and finely touched as verse. Other productions in verse and prose have long passed into oblivion. The poetical works were collected in 1808 (2 vols.) by the author's son John, himself author of *The Pleader's Guide*, in the same vein with the *New Bath Guide*. He died on 3d August 1805. (A. B. G.)

ANSTRUTHER-EASTER, a royal and parliamentary burgh of Scotland, in the county of Fife, situated on the Firth of Forth, 9 miles S. of St Andrews. It is on the whole an ill-built place, containing tanning, shipbuilding, and fish-curing establishments, and carrying on a considerable amount of sea-fishing and some coasting trade, to accommodate which a new harbour is in course of construction, under the direction of the Board of Fisheries. In 1871 the parliamentary burgh, which, along with Anstruther-Wester, Crail, Cupar, Kilrenny, Pittenweem, and St Andrews, returns one member to parliament, contained 1289 inhabitants; the royal burgh had a population of 1169. Dr Thomas Chalmers was born at Anstruther-Easter in 1780.

ANSTRUTHER-WESTER, also a royal and parliamentary burgh in Fifeshire, close to Anstruther-Easter, from which it is separated by a small stream called the Dreal Burn. In 1871 the population was 484.

ANT. The insects included under this name are divisible into two distinct groups, which exhibit important differences not only in structure but also in habits. The familiar ant (*Formica*), found in Britain and Europe generally, belongs to an order of insects known as the *Hymenoptera*, of which division the bees, wasps, hornets, are also well-known examples. But the *Termites*, or white ants—insects which also live in social communities, and which inhabit tropical regions—belong to a different order, that of the *Neuropterous* insects, and exhibit differences in several important respects from the ordinary ants. To both species or kinds of these forms it will be necessary to direct attention, and the familiar ants naturally fall to be considered first.

The Hymenopterous insects are distinguished by the possession of four membranous wings, although in certain exceptional instances—as among certain members of the ant community—the wings may be wanting. The organs of the mouth are partly fitted for mastication by the development of jaws, and partly for suctorial purposes by the possession of a proboscis or "antlia." The females of this order generally possess a terminal abdominal appendage, forming a "sting" (*aculeus*), or which may be used in the deposition of the eggs, when it is termed an *ovipositor*. The Hymenoptera, besides, undergo a "complete" metamorphosis,—that is, in their passage from the egg towards adult or mature existence they appear first as grubs, or *larvæ*, then are enclosed in a pupa-case, and finally appear as the perfect, and generally winged insect, or "imago." The Hymenoptera exhibit, perhaps, the most remarkable development among insects of the faculty of instinct, and constitute excellent examples of so-called "social" insects, living in communities regulated by definite laws, each member of the society bearing a separate and well defined part in the organisation and arrangement of the colony at large.

From the earliest times ants have attracted the attention, not only of naturalists, but of philosophers and poets. The ancients were familiar with many of the phenomena characteristic of the ant colony. Aristotle and Pliny, for example, inform us that the labours of ants are regulated in a great measure by the phases of the moon. Pliny also makes mention of a species which he alleges is found in Northern India, which were said to equal Egyptian wolves in size, and were supposed to occupy themselves in digging gold from the bowels of the earth, whilst the inhabitants of the country were said to rob the ants in summer of their accumulated winter treasures.

The harvesting and grain-storing habits of ants, so familiar to the popular reader, were at first supposed to be common to *all* species of ants, but this view has been abundantly proved to be erroneous, whilst the opposite extreme of asserting that no species practise these habits is to be viewed as equally incorrect. In many cases it is probable that observers have been deceived into the supposition that certain species of ants really carried grains of corn in their mouths, whereas the so-called corn grains of these species were in reality the cocoons or pupæ-cases containing the young and immature forms. And whilst most species of ants are granivorous, or vegetable feeders, certain species are as decidedly carnivorous. These latter kinds do not, therefore, participate in the frugal and industrious habits of their allies.

The bibliography of ants is very extensive. Dr King, in the 23rd number of the *Philosophical Transactions*, described the form of the eggs and of the larvæ, and also the habits of ants in reference to their care of their young. Leeuwenhoeck, the Dutch naturalist, traced the successive stages of development in the ants, and demonstrated the egg, "larva," "pupa," and "imago," or perfect insect. Swammerdam, with the application of the microscope, further advanced the knowledge of the development and structure of the ants, and Linnæus (*Memoirs of the Royal Academy of Sciences of Stockholm*) ascertained many facts relative to the reproduction of these forms, and determined that the winged ants are those which alone exercise the generative functions. A Mr Gould published *An Account of English Ants*, of which work a notice by the Rev. Dr Miles is given in the *Philosophical Transactions* for 1747. This account, excellent in many respects, is nevertheless erroneous in certain points,—the result of following too closely the analogy presumed to exist between bees and ants. Geoffroy (*Histoire des Insectes qui se trouvent aux Environs de Paris*), a good naturalist otherwise, is a bad authority on the subject of ants. The most complete series of observations on ants, which appeared among the earlier accounts of these forms, are those of De Geer, a Swedish entomologist (*Mémoires pour servir à l'Histoire des Insectes*), an observer on whose fidelity the utmost reliance may be placed. Olivier, in the *Encyclopédie Méthodique* (article *Fourmi*), summarised the knowledge of his own and of preceding times, and described a few new species of ants; and Bonnet, in his *Observations sur les Insectes* (vol. ii.), has given us some interesting, though by no means extensive information regarding the habits of ants. The "sugar-ant" (?) forms the subject of a memoir in the *Philosophical Transactions* for 1790, this latter species having caused much havoc among the sugar-plantations of Grenada over a period of ten years. Latreille, a famous entomologist, in his special monograph (*Histoire Naturelle des Fourmis*), published at Paris in 1802, gave the most succinct and accurate account of the ant-tribe which had appeared up to that date. His description of the structure and classification of these insects is remarkably clear, and he fully describes one hundred species known to himself, and mentions twenty-four species which he was enabled to describe from the reports of others. He distributed these species among nine families, selecting as the bases of his classification the situation and structure of the "antennæ" or "feelers," and the disposition of the abdominal scales.

The habits of ants receive the fullest attention at the hands of Pierre Huber of Geneva, who in a treatise (*Traité des Mœurs des Fourmis Indigènes*) published in 1810, gave a very interesting, lucid, and valuable account of his native ants, drawn from actual observation of the nests and communities. This result he achieved by means of an apparatus which enabled him to view the interior of the nest. Many facts have been added to the history of ants since 1810; the list of works and treatises upon this and allied entomological pursuits having been largely increased, especially of late years.

The constitution of an ant-community may be readily appreciated; but it is, at the same time, important to note the distinctions between the various groups or sects into which the curious colony is divided. A threefold distinction of sex, resulting in the production of three kinds of individual forms, is to be perceived in the ant-colony, as well as among other hymenopterous insects (*e.g.* bees). These three grades of individuals are known respectively as males, females, and neuters. The males and females

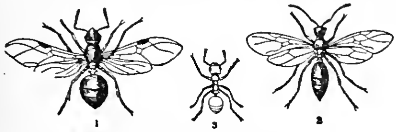

Fig 1.—Wood Ant (*Formica rufa*). 1, Female; 2, Male; 3, Neuter.

are winged,—the former retaining their wings throughout life, and the latter losing these organs after the pairing is over. During the summer the winged males and females are produced in large numbers, and they soon leave the nest to take their "nuptial flight" in the air, in the course of which the females are impregnated. The function of the male ants having been thus performed, they die; the females, after impregnation, lose their wings; and whilst in this comparatively helpless state they are conveyed by the neuters to new situations, where they become the founders of fresh colonies.

Each fertile female or "queen" is carefully attended by a retinue of "neuters," the latter being simply females the sexual organs of which are undeveloped. The curious experiments of entomologists have proved that, in all probability, the cause of this differentiation of sex is dependent upon the nature of the food with which during the larval state the ant is fed. Exempted thus from all sexual functions, the duties of the neuters are confined to the performance of all the offices which contribute to, or are connected with, the welfare and labour of the ant-community. They thus not only construct and build the nest or home, and keep it in constant and assiduous repair, but they are also the providers of food and sustenance for the community; and they act the part of nurses, in that they carefully attend to the hatching, nutrition, and rearing of the young. They are also the defenders of the colony, in that they protect the nest and its inmates from the attacks and assaults of nearly-related enemies or foreign foes. In connection with the defence of the ant-colony, certain species possess peculiar neuters, termed "soldiers," upon which the care and protection of the community more especially devolve. These "soldiers" are provided with large mandibles or biting-jaws, which constitute efficient organs of offence or defence; and they are distinguished from the ordinary neuters by several characteristics in addition to this larger development of the jaws.

Regarding the more intimate structural differences which have been ascertained to exist between the various members of the ant-community, it may be remarked that the antennæ of the male ants possess thirteen joints each, and those of the female twelve. The antennæ of the neuters are composed of twelve joints. The abdomen of the male ant consists of seven joints, and that of the female and neuter of six. The mandibles or large jaws of the female and neuter ants are larger than those of the males, and are frequently found to be serrated or even hooked at their extremities. The external sexual organs of the neuters correspond to those of the females, although, as already remarked, the essential internal reproductive organs are wholly undeveloped in the neuter ants; and to this most important distinction there is added the absence of wings, the neuters being thus distinguished from the females by a variety of characters, while the near relation is at the same time shown of the one series of truly sexual forms to those in which the sex is undeveloped. The neuters, it may lastly be remarked, conform to the female characteristics, in having the abdomen provided with a sting, the male ants being destitute of this appendage.

The nervous system of the ants conforms to the ordinary insect-type; but in these and other insect forms, we find the highest development of those faculties to which the general name of *Instinct* is applied. By instinctive acts, in their simplest sense, we mean those acts which an animal performs chiefly from impressions made by surrounding objects upon its nervous or sensory apparatus. These are very different in character and origin from the actions of the higher vertebrate animals, in which the independent faculty of *mind* operates as the direct source of action, in place of the surrounding circumstances of the lower form. Thus, in the case of ants, bees, &c., wonderful as their operations may appear, and regular and methodical as the manner in which they are performed may seem, it will be found that a marked uniformity and likeness of conditions exist, which tend to produce a corresponding similarity of effects. The same external conditions thus tend to induce undeviatingly similar series of phenomena, and under the operation of these acts the animal exercising them may justly be compared to an automatic machine, or to a piece of mechanism, self-directing only in so far as it is directed by external circumstances and outside conditions. Hence we find certain species of ants or bees invariably constructing similar series of cells or habitations, and engaging in the same labours as their predecessors, which labours or operations will be faithfully and exactly repeated by succeeding generations. And the automatic and mechanical nature of instinctive acts may be clearly viewed when we contrast them in their essential nature with the directing intelligence and guiding impulse of mind, as we find these qualities exercised in the highest vertebrates. In the latter case, the mental impulse itself directs alike the physical and psychical operations, and so far from the animal being merely automatic, it assumes the higher phase of nervous action involved in self-originating mental impulse. The actions of the intelligent being are self-determined: those of the instinctive being originate from the outer world. Through the higher nervous centres the intelligent being first appreciates the outward circumstances, and then reacts upon them; the nervous centres of the lower being are, in the first instance, acted upon by the outer world, and then in their turn react upon the organism. Lastly, and in accordance with the more perfect appreciation of external objects through sensations and perceptions, we have to note in the higher being the operation of the educative power we entitle *experience*. The ant or bee, when first introduced into the special sphere of its labours, assumes its functions, and performs its duties as perfectly as if it had been engaged in their performance for a lengthened period. And the long-continued performance of these duties will in no degree tend to make the ant or bee a more perfect or more skilful worker than when the performance of the duties first commenced. Here, again, we observe the operation of the automatic powers; the lower animal, like the perfected machine, operates at once and without any previous experience as perfectly as after a lengthened period of working. But, in the higher operations directed by intelligence, the being acquires in a gradual manner, and only after a lengthened experience, the perfect manner of working. In the one case instinct incites the being automatically, or through the excitory outward impressions, to perform the acts; in the other, an intelligent mind first appreciates the impressions, and, through the educative training of experience, is enabled to perform the acts, and to understand in a greater or less degree the reasons which prompt and justify them.

Apart from the possession of high instincts, however, we find ants, in common with many other insects, to be possessed of very perfect senses. In addition to the large compound eyes with which most insects are provided, they possess simple organs of vision. The sense of smell also appears to be represented in the ants and insects generally, but the seat of this sense has not been well or satisfactorily determined. Judging from analogy, however, the olfactory apparatus has been supposed to reside in the basal joints of the feelers or antennæ. Ants have been long observed to follow accurately the track of their companions. Bonnet concluded that they were enabled to follow up this line of march by their scent, and in proof of this he repeatedly drew his finger at various parts across the line of march. The ants, on arriving at the interrupted spots, seemed to lose scent, and directed their steps in an irregular and hesitating manner, but having once crossed the interrupted space of the finger track, they resumed their journey once more in a regular manner along the line of march. Latreille, with the view of ascertaining if the sense of smell resided in the antennæ, cut off these organs in several ants, when he found that they appeared to lose their way, and to be incapable of directing their further steps. It may, however, on obvious grounds be doubted whether this experiment may be deemed at all satisfactory or conclusive on the point. In this experiment it was noticed that the neighbouring ants appeared to observe the distress of their mutilated companions, and they seemed to stanch the wounds of the sufferers by an application of the organs of the mouth to the wounded surface.

The antennæ in insects are certainly the organs of touch, but in ants these organs appear to subserve some undetermined function, in that through their agency communication may be made from one ant to the other. M. Huber was so strongly impressed with this latter fact, that he applied the term *langage antennal* to the intercourse which he supposed took place between ants through the media of the antennæ. For example, by each ant striking its head against its neighbour, and by the transmission of this impulse, the whole ant-community appeared to be warned of danger, and in other ways, but chiefly through the antennæ, the sense of danger appears to be appreciated by each member of the colony.

The food of ants has formed a debatable point ever since the attention of naturalists was directed to the investigation of their economy. As already remarked, many species are truly carnivorous, and prey upon the soft parts of other insects, and particularly of larvæ, which they are enabled to seize and capture with little danger and trouble. The well-known partiality of ants for animal food is taken advantage of by those who wish to obtain the hard parts or skeletons of animal forms; since by placing an animal body within reach of an ant-colony, the soft parts are gradually eaten away, and the harder portions are left intact. In tropical climates, rats, mice, and poultry, even in a living state, are said to succumb to the attack of these creatures; and man himself, as related by Prévost in his *Histoire Général des Voyages*, is even subject to the attacks of ants. Prévost relates that an Italian missionary in Congo was awakened from sleep by his negroes, with the intelligence that an immense horde of ants was invading his house. Before he could rise they had already covered his legs, and the floor of his house was carpeted by a thick layer of the invading forms. Fire seemed to be the only preventive to their onward march; and it was stated that cows were known to be devoured in their stalls by these creatures. These remarks may be viewed as applying more particularly to the *white ants* or *termites*, of which an account will be given afterwards. For *sugar* ants seem to have a special predilection; and they appear not only to obtain the saccharine matter from vegetables, but also to abstract it from animal sources. The *aphides*, or plant lice, become in this way the subjects of very extraordinary attentions on the part of ants. The plant lice possess a glandular structure, situated at the extremity of the abdomen, which communicates with the external surface by two small ducts. This gland secretes a sweet or saccharine liquid of viscous nature, of which ants are extremely fond, and the *aphides* appear to be literally "milked" by their smaller neighbours. The antennæ of the ants in this case also appear to be the media of intercourse between the *aphides* and themselves, and by touching the abdomen of the plant lice with the antennæ, a drop of the saccharine liquid exudes from the gland, which is eagerly seized upon by the ants; and in this fashion the milking process is continued until the ant is satisfied. The *aphides*, in this instance, appear voluntarily to surrender themselves for the purpose of affording the saccharine matter; but it has been also alleged that certain species of ants keep *aphides* within their nests for the purpose of affording the desired matter. Whether or not this alleged domestication of the aphides by ants is to be deemed worthy of belief yet remains to be proved. A single *aphis* may be occasionally seen surrounded by three or four ants,—the latter ordinarily finding the *aphides* on the leaves of plants and in their natural habitat. The association of ants and aphides, strange as it may seem, is not, however, without its parallels in the history of the ant-colony. Thus wood-lice are not infrequently found as apparently normal guests within the ant-nest; and Siva of Pisa observed a species of grasshopper, to which he has given the name *Gryllus myrmecophilus*, which inhabits the nest of an Italian ant. The ant-nest, in fact, appears to be the normal habitation of this grasshopper.

The ant-nest forms a very interesting subject for consideration, and the various groups of ants differ widely in the outward form and internal plan according to which the nests are constructed, as well as in the materials of which the habitations are built. Clay, earth, and vegetable matters form the chief sources of supply, and excavations in the ground, or erections above ground, in trees, walls, and house-roofs, may be mentioned as the most common situations for the nests. The internal arrangement also varies even to a greater extent than the external appearance or materials. The general plan of the nest shows an arrangement of flats or stories, connected throughout by passages, and supported by definite pillars or partitions. The chief ends and objects in the construction of the nest appear to be directed to the preservation of the larvæ, and to their protection from changes of temperature. During the night the larvæ are placed in the furthest chambers of the nest, the entrance to the nest being carefully secured for warmth and for ensuring protection from the raids of enemies. In the morning the larvæ are transferred by the diligent neuters to the outer chambers, to which the sun's heat has access; or they may even be exposed directly to the sun. A change of temperature or weather is sufficient to set the watchful neuters on the alert, and to cause them to hurry the larvæ to the inner recesses of the abode, where they may be safely protected from the variable effects of the climate.

Some of the most curious and extraordinary traits in ant-character relate to the acquiring by certain ants (*e.g.* Amazon-ants) of the pupæ or immature young of other species, and the training and subjection of these pupæ as slaves and servitors. Regular raids and forays appear to be made by the slave-making ants upon the nests of certain species, the pupæ of which are captured, and when developed brought into bondage and subjection to the captors.

No closer imitation of the ways of man could well be found in the entire animal economy; and the circumstances of these curious cases have been so thoroughly investigated that the matter is placed above the possibility of doubt or error. The relative position of the masters and slaves varies greatly, the extreme of hard servitorship being seen in some cases, whilst in other cases the position of the slaves is much easier. The slaves of *Formica sanguinea* are aided by their masters in the work of the colony. But in the case of *Formica rufescens* the labours of the slaves are greatly increased,—the entire work of the community devolving upon the unfortunate captives, and the neuters, laborious in other species, being merely employed in the duty of capturing fresh servitors. This latter trait also appears among the Amazon-ants, which literally stir neither "hand nor foot," nor make any effort to help themselves, but are waited upon and attended in the most devoted manner by their willing serfs. The slave-making forays are by no means invariably destitute of bloodshed or warfare, and frequent and hot combats appear to be engaged in between the would-be masters and the species of intended slaves. Once captured, developed, and domiciled within the nests of their masters, the slave-ants appear to be thoroughly at home, and no effort at insurrection or attempt to gain their freedom appears ever to be made. The early state of development in which the pupæ are generally captured, would necessarily favour the complete domestication of the captured ants within the home of the slave-making community; and the ants appear to possess and exhibit the greatest care and solicitation for the welfare of their serfs, —the slaves being carried in the mouths of their owners when the latter shift their abode, or undertake any expedition leading them from home.

From the accounts of Messrs Bates and Belt, we gain some curious and interesting information regarding species of ants peculiar to South and Central America, which exhibit marked differences in habits from all British or even other foreign species. Chief among these South American ants are the *Foraging* Ants (*Eciton*), of which there are several distinct species. These ants are truly carnivorous in their tastes, and ravage whole districts, their march being regarded with terror by the natives of Central America. Mr Bates tells us that different species have different modes of marching, by which they may be recognised. The Ecitons in Nicaragua are termed "Army Ants," and they appear regularly to change their hunting-grounds in quest of food. Their community comprises males and females, and two kinds of neuters or workers—a "worker-major," or large-headed worker, and a small-headed kind, termed the "worker-minors." The former kind are noted for their elongated jaws; and in some species these forms are denominated "soldiers," their peculiar office being the protection of the community from the attacks of enemies, or the making forays on the nests of other species, or upon other animals. The habit the Ecitons have of hunting in regular organised bands distinguishes them from other and more familiar British species (*e.g.*, *Myrmica*, the Red Stinging Ant of Britain), which are predatory, but hunt in an irregular and ill-defined manner. One of the best-defined species of foraging ants is the *Eciton predator*, a small species which hunts in dense hordes, and marches rapidly over a territory. A moving phalanx of this species will extend over from 4 to 6 square yards; and any unwary insect meeting with, or falling into the serried ranks, is soon torn to pieces and devoured. *Eciton hamata* hunts both in dense masses or in detached columns. The nature of the prey appears to regulate the mode of march. Thus, when proceeding in columns, Mr Belt found that the *Eciton hamata* was in search of the nests of another ant (*Hypoclinea*), the larvæ and pupæ of which are seized by the Ecitons for the purpose of being brought up as slaves, in accordance with the habits already alluded to. The Hypoclineas rush out on being attacked, bearing their pupæ and larvæ in their jaws; but the Ecitons at once seize the young ants, although they never appear to injure the parent Hypoclineas. The latter appear a cowardly race, as they make no effort at self-defence, their habits leading them chiefly to milk *aphides*, which they desert at once on seeing another and even smaller species of ant approach. Birds and opossums are terrified, as well as insects, at the Foraging Ants, and frequently fall victims to the determined onslaught of the little furies.

The other species of Ecitons comprise *Eciton rapax*, the largest of the race, the body of which is half-an-inch in length; *Eciton legionis*, famed for its ravages on other species of ants (*Formicæ*); *Eciton hamata* and *E. drepanophora*, nearly related species; and the so-called *Blind Ecitons*, thus named from the imperfect condition of the eyes. The *E. vastator* and *E. erratica*, species of blind Ecitons, proceed on their raids by means of covered roads or ways, which are excavated and formed in front at a rate corresponding to the advance of the army.

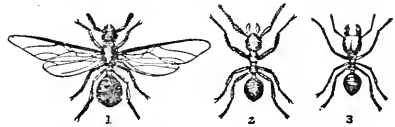

FIG. 2.—Leaf-cutting and Foraging Ants. 1, *Œcodoma cephalus*; 2, *Eciton drepanophora*; 3, *Eciton erratica*.

Some interesting information regarding the senses and instincts of the Foraging Ants appears to corroborate the opinions of some earlier observers, already alluded to, on the subject. About a dozen individuals of *Eciton hamata* were observed to assemble together, as if in consultation, in a tramway excavation in Nicaragua. One ant suddenly left the assembly, and ran up the perpendicular side of the cutting. The example of this first ant was followed by several others, which ran after the first ant for a short distance, then returned, and again proceeded for a farther distance along the track of the first. The object of this proceeding was to make the track readily determinable by the succeeding travellers, and the route of the first individual was unerringly followed by the others, who were at long distances behind. A portion of the trail was removed, when the ants appeared at fault, and occupied themselves in making detours until they again hit upon the interrupted track. On arriving at the top of the excavation, a suitable spot for hunting was descried, when the information appeared to be quickly communicated to those that were below, and the whole army rushed upwards in obedience to the behest of the scouts. All the Foraging Ants are migratory in habits, and appear to possess no fixed place of abode, but shift their camp at intervals of from four to six or more days. The temporary abode is found in hollow trees, or under fallen trunks. An Eciton, intentionally imprisoned beneath a stone, was discovered by a companion, who at once informed his neighbours. The other ants then came to the rescue; and by biting at the stone, trying to move it, and seizing the prisoned ant by the legs, they, by their united efforts, set their companion free. An ant embedded in clay, with only the points of the antennæ protruding, was discovered by his neighbours, and soon disentombed. And in cases where the efforts of one ant have been inadequate to release a comrade placed in peril, the others were duly informed of the fact, and hurried to assist their less fortunate neighbour. In crossing a crumbling slope, which was gradually disintegrating under the passage of the ant-army, a portion of the band, by adhering to each other, formed a solid pathway, over which the others passed safely. A twig formed a bridge across a small rill; but this proving insufficient and too narrow for the transit of the army, it was widened by ants clinging to each side of the twig, and in this way the track was broadened sufficiently to admit of the easy passage of the mass. Such acts would appear to lie beyond the category of purely instinctive processes, since they appear to involve an adaptation of faculties to special cases, and result in special actions being instituted, and thus bear some resemblance to what we familiarly see involved in the process of reasoning characteristic of man's mental powers. The more ordinary operations of ant-life are purely instinctive, as has been already shown; but it may be a matter for consideration if the theory of some naturalists, that the higher development of instinctive powers is akin to reason itself, may not be tenable. Such instances as these just given of the curious and extraordinary acts of the Foraging Ants may serve to show from what circumstances the theory obtains support. Houzeau, in particular, among recent writers, adopts analogous views to these, and maintains that the ants most nearly approach man in the arrangement and general nature of their social existence and condition.

The Leaf-cutting Ants (*Œcodoma*) are noted pests of central and tropical America; and, as is implied by their name, commit fearful havoc among trees, laboriously and persistently carrying off in their mouths, piece by piece, the foliage of trees and shrubs. The orange, lemon, and mango trees in particular have suffered from their attacks. Carbolic acid has been tried with success as a remedy against these ants, the use of this antiseptic killing large numbers; and corrosive sublimate in powder, sprinkled across their paths, has a deadly effect upon the leaf-cutters. Coal tar has also been employed against them. Gigantic black ants, averaging an inch in length, are found in Central America. They are notable as being solitary in their habits, and possess well-developed eyes and formidable stings. These forms contrast with the gregarious and social ants, in which the eyes are comparatively weak, or may be rudimentary.

Certain curious little ants (*Pseudomyrma bicolor*) inhabit the hollow thorns of the "bull's horn" acacia of Central America. The horn-like thorns form the nest, the aperture being situated near the tip of the thorn. These ants preserve the plant from the attack of the Leaf-cutting Ants, and also from mammals feeding upon it. The ants obtain a supply of food from the plant, in the shape of a honey-like secretion, found in a gland situated at the base of the leaflets. Protected by, and at the same time protecting the plant, the intimate relations between the acacia and the ants may be argued to possess a deeper significance than relates to a merely casual or chance connection. The *Cecropia*, or trumpet tree of Central America, is tenanted by ants, which obtain a sweet fluid, through the agency of brown scale-insects (*Coccidæ*), kept by them in the cells of the trunk. This recalls the case of the *aphides*, or ordinary plant lice, the ants sucking the fluid from the scale-insects through a dorsal or back-pore. The queen-ant in her royal cell is attended by a special bevy of *Coccidæ*, who supply her with the requisite food. The *Coccidæ* in America take the place of the European *aphides* as ant-cows, but the tropical ants appear to attach themselves to other insects also. Thus, the leaf-hoppers (*Membracis*) are attended by ants, for the sake of the honey which the larvæ exude. Those insects which are attended by ants are protected from the attacks of other animal forms; and the shelter given to the ants thus serves to protect the tree or shrub, and to save it from becoming exterminated.

The "soldier ants," referred to in the foregoing account of the Foraging Ants, are not peculiar to that race, many other species also possessing "soldiers." These forms, as has been already stated, appear to be merely neuters which have the jaws very largely developed, for the protection of the true neuters or workers, and for the defence of the nest generally. This further subdivision of the ant-community would seem to indicate an additional approach to the social arrangements which characterise the human state.

The reproduction and development of the ordinary ants may be very briefly touched upon in the present notice. The impregnation of the females in their aerial nuptial flight has been already alluded to, as also has the death of the males after the congress. The impregnated females are conveyed to the nest, and the deposition of eggs is proceeded with, the young forms being tended through their larvæ and pupæ stages by the assiduous neuters. Unlike the bees, several female ants may inhabit the same nest; and the swarming or exodus of the young ants, so far from having for its one and essential object the formation of a new colony, appears to be simply devoted to further reproductive measures. Thus, those that leave the nest are the fresh males and females, the sexual history of which has already been traced; and the nest thus remains a more or less permanent institution, changing its inmates only in part, and in exceptional circumstances alone giving origin to a new and independent colony.

The stings with which the neuters and females are armed constitute formidable organs of defence. The poison, to which the violent or painful effects of the sting are due, appears to consist of a definite chemical organic compound, the chief acid of which is known by the appropriate name of *formic acid*, the formula for this compound being CH_2O_2. Formic acid is also found in the glands attached to the pointed hairs of stinging-nettles. This acid, in itself possessing irritant qualities of a high order, also appears capable of producing even more serious effects when manipulated by chemical means.

The ant-colony, powerful as we have seen it to be, and well protected as it undoubtedly is, is nevertheless subject to the attacks of enemies which wage a successful war against it. Certain species of ants appear to be more subject than others to the attack of such higher forms as the mammalian ant-eaters (*Echidna* and *Myrmecophagidæ*) and armadillos, as well as to the onslaught of the insect ant-lion (*Myrmeleo*). The latter literally digs a pit for his

FIG. 3.—Ant-lion (*Myrmeleo formicaleo*).

victim, in the bottom of which he lies securely hidden, ready to devour any unwary ant which may chance to tumble in. And even where the victim is not within actual reach of the *Myrmeleo*, the latter by means of a shower of sand-particles frequently succeeds in causing it to fall into the snare. Several substances which have a noxious effect upon the ant-colony have been already mentioned. Thus carbolic acid and corrosive sublimate appear to affect the ant-colony as poisonous agents; and solutions of tobacco, lime, soot, and walnut leaves, with urine, are also stated to prove effectual in destroying them, although these latter are decidedly inferior to the two first-mentioned substances. Corrosive sublimate, indeed, appears to have a curious and even specific action upon these forms, in rendering them actually *maniacal*, to use a phrase which is applicable generally to the human subject alone. Under the influence even of external contact with this substance, the ants in Grenada during their ravages of last century, were observed to be singularly affected, and were seen even to attack each other with outrageous violence,—an effect also corroborated of late years in Central America by Mr Belt, who saw the rabid ants collected into small balls biting one another, and seizing hold of each other in a most extraordinary fashion under the influence of the mercurial poison. The corrosive sublimate, it is stated, can be effectively used only in dry weather.

White ants. A brief description of the *Termites*, or white ants, may appropriately conclude the present article. These forms have already been stated to be entirely different from the familiar and true ants, and to belong to the Neuropterous insects, whereas the true ants are classed with the *Hymenoptera*. They resemble the true ants in living in highly organised social communities, and in being endowed with as high and as specialised instincts. But they differ from them, first, in the fact that they do not undergo a complete metamorphosis, that is, the Termite larvæ and pupæ resemble the perfect insect, and do not pass through the defined stages of change and development characteristic of the true ants, bees, and other insects. The young Termite, in fact, differs from the ordinary adult only in the non-possession of eyes, and from the sexual forms in the non-development of wings. The white ants inhabit the tropical regions of the world generally, but are found in the greatest abundance in tropical South America. Their nests form characteristic structures, rising sometimes to a height of 5 or 6 feet, and constructed of earthy particles worked into a mass as hard and durable as stone. Many species of Termites are known, but they resemble one another in essential structure and habits. As indicated by their popular name, they are of a whitish colour and are soft-bodied. The Termite community consists, as in the true ants, of males, females, and workers or neuters. In the true ants the latter are undeveloped females, whereas in the Termites the sex of the neuters is wholly undeterminable; and in addition the workers are invariably divided into two distinct classes: the "soldiers," with largely-developed jaws, whose sole office is to defend the community; and the ordinary "workers," on whom devolves the entire labour of the nest. Both classes of neuters are blind; and from a close examination of the eggs, the distinctions, not only between males and females, but also between the soldiers and workers, may be easily seen. The difference in food, so powerful in the development of sex and characteristics in other insects, does not therefore operate in the case of the Termites. The entire white ant colony and species also exhibits a division into subordinate groups and classes, the recognition and characters of which are very difficult of determination. And on this, as well as upon other grounds, the organisation of the white ant community is generally to be regarded as of a higher type than that of the familiar and true ants.

Fig. 4.—White Ant (*Termes bellicosus*). Male.

Fig. 5.—White Ant (*Termes bellicosus*). Soldier.

The nest of the Termites is known as a *termitarium*, the essential internal arrangement of which consists of a large number and series of chambers, connected by galleries and passages. Entrance to the nest is afforded by concealed roads and subterranean passages. A large hillock may be a compound termitarium, formed by and inhabited by different species; and certain kinds of Termites build their nests of smaller size, sometimes of the consistence of paper. Their structures may be attached to the branches of trees, or they may be entirely subterranean, or concealed under the bark or within the stems of trees. The latter species are those which destroy timber, furniture, and household objects.

Within this curious home an equally curious community is found to reside. The king and queen represent the sexual part of the community, the true neuters or workers form the greater part of the ordinary individuals, and the soldiers and winged Termites complete the list of inmates. The royal cells, tenanted by the king and queen, exist in the inmost part of the nest, and are closely guarded by a retinue of workers. The king and queen are wingless and much larger than the neuter ants. The queen Termite when within the royal cell is permanently gravid, the abdomen being immensely distended with eggs, which as they are produced, are seized upon by the workers,

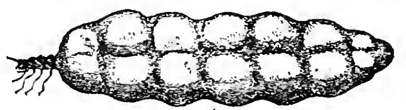

Fig. 6.—White Ant (*Termes bellicosus*). Gravid female.

and conveyed to special cells prepared for their reception. The relations of the winged Termites to the other members of the nest long formed a subject of great difficulty to naturalists; but they appear to be males and females, which are ready to assume sexual relations, and to become the progenitors or kings and queens of new communities. The neuters are, accordingly, quite distinct from the sexual forms, and do not pass through any similar developmental phases, but differ from the others, even in the egg, as has been already mentioned. Occasionally a new termitarium may be found, in which a king and queen are absent, and which contains workers only. These, however, gradually prepare the nest for full completion, by bringing eggs into the cells from a neighbouring termitarium, from which the due population of the colony will be in time produced.

The exodus or swarming of the Termites appears to resemble more nearly that of the bees, although like that of the true ants, it is more purely reproductive in its nature, and not so much connected with the departure of fully grown forms from a hive which has become inadequate to the comfortable accommodation of all its inmates. The larvæ, prior to the swarming, are fed and tended by the workers, the youngest larvæ receiving the greatest share of attention. The workers apparently feed the larvæ by injecting a fluid from their mouths into the larval cells; and in about a year after the deposition of the eggs the larvæ become fully grown, and the period of the exodus arrives. The exodus generally takes place on damp evenings, or cloudy mornings, and many extend over several days, or until such time as all the males and females have emerged from the nest. Having reached the ground, the wings of each ant are shed by a natural effect—a seam or place of separation existing at the roots of the wings—and after the throwing off of the wings, the surviving males and females pair, and become the parents of new colonies. Many fall victims to the attacks of enemies, as spiders, bats, lizards, toads, and goat-suckers. The pairs that survive take up their abode in some secluded situation, as under leaves, or under a clod of earth; there the females become impregnated, and by-and-by a new hive and its population are produced. The Termites serve an important purpose, in the particular areas of the world they inhabit, in disintegrating, removing, and destroying decaying wood.

ANTÆUS, in Greek Mythology, a giant of Lybia, the son of Poseidon and Ge (Terra). He compelled all strangers passing through the country to wrestle with him, and as, when thrown, he derived fresh strength from each successive contact with his mother earth, he proved invincible. With the skulls of those whom he had slain he built a temple to his father. Hercules, in combat with him, discovered the source of his strength, and lifting him up from the earth crushed him to death. The struggle between Antæus and Hercules is a favourite subject in ancient sculpture.

ANTALCIDAS, a Spartan politician, who rendered conspicuous service to his native state at one of the turning-points in Greek history. He comes first into notice as ambassador from Sparta to Tiribazus, the Persian satrap of Ionia, to sue for peace (393–2 B.C.) Upon hearing of this the Athenians, becoming anxious lest they should lose their growing ascendency, also sent an embassy, at the head of which was Conon, to counteract the efforts of the Spartans. Tiribazus favoured the cause of Sparta, and secretly supplied Antalcidas with the means of carrying on war against Athens. Artaxerxes, however, disapproving the conduct of his satrap, recalled him, and appointed Struthas, whose sympathies were on the side of Athens, in his place. But this check to the policy of Antalcidas was only temporary. In a few years circumstances became even more favourable than at first to a successful negotiation, Tiribazus having been restored to his satrapy, and accordingly, in 388–7, Antalcidas was again sent upon an embassy to Asia. By skilful diplomacy he succeeded in securing the active assistance of the Persian power against Athens. Appointed on his return admiral of the Spartan fleet, he carried on a naval warfare in a manner so vigorous, that the Athenians were glad to accept peace on the terms Artaxerxes chose to dictate. These were made known by Tiribazus to a congress of deputies from Sparta, Argos, and Athens, and formed the basis of "the peace of Antalcidas," so called from its being arranged in accordance with the views of the Spartan ambassador. Antalcidas seems to have been engaged in another mission to Persia in 371; but the later incidents of his career are involved in uncertainty. Plutarch states that he committed suicide on the failure of his last mission, but there seems no proof of this.

ANTALO, a town of Tigré, in Abyssinia, capital of the district of Enderta, situated in lat. 13° 17′ N., and long. 39° 28′ E., on a plateau about 8000 feet above the level of the sea, out of which a steep hill rises on the north of the town, while beneath it a wide plain stretches southward. A large part of Antalo is now in ruins, but it still possesses a weekly market of considerable importance, and contains several churches. Its population was once estimated at 8000.

ANTARA, or, as he is usually called, ANTAR, an early Arabian warrior and poet, famous as the author of one of the poems hung up in the Kaaba at Mecca, and as the hero of a romance which bears somewhat the same relation to Arabic literature which the Arthurian legend bears to our own. He was the son of Shedad-el-Absi, a warrior in the army of Zoheir, by Zabuba, a negro slave who had been captured in some plundering expedition; and, if we can trust the Arabian romancist, he bore strong evidence of his negro origin. He spent his youth in servitude and neglect, but soon became known for his strength and high-handedness. Before long, while yet a slave, he fell in love with his cousin, the beautiful Abla, whose praises are still preserved at Mecca, but at the same time had the misfortune to incur the hate of his father's wife, Shameeah. A number, however, of happy opportunities presenting themselves, he showed such extraordinary prowess against some hostile tribes, that his father was constrained to join in the public appreciation of his services, and to recognise him as his son. He now gradually rose in favour, and held for long a position of the greatest influence among his people, filling the surrounding country with the fame equally of his song and his sword. In a great war between two rival tribes, which lasted forty years, he is said to have played a very prominent part. The time and manner of his death are matter of dispute,—Ibn Doreid making him be slain by Wasr-ben-Jaber, while, according to Abu Obeida, he died a natural death when well stricken in years. Wherever the Arabic language is known his fame is still green · and frequent references are made to *Chubli Antar*, *Istabli Antar*, Antar's house and Antar's stable. By whom the romantic account of his life was originally written is far from being satisfactorily decided; but it is generally ascribed to Asmai, who lived at the court of Harun-al-Rashid. It is composed in rhythmic prose, interspersed with fragments of verse, many of which are attributed to Antar himself. The style is remarkably pure, and a picture is afforded of early Arabian life that is equally graphic and minute. The romance, which in its fuller form extends to fifty or sixty MS. volumes, was first brought under European notice in 1802 by Von Hammer, who, after repeated perusal, spoke of it as surpassing the *Arabian Nights* in interest and beauty. Sir William Jones had already written in the highest terms about a part of it which had fallen in his way. In 1820 Terrick Hamilton, brother of W. Hamilton, the author of *Ægyptiaca*, published a translation of a portion of it from a condensed Syrian manuscript obtained at Aleppo; and this gave occasion for a number of articles on Antar in our periodical literature. (See Von Hammer, *Mines de l'Orient*, 1802; Arnold's *Moallakat*, Leipsic, 1850; Ahlwardt's *Divans of Six Ancient Arabic Poets*, London, 1870; Kitto's *Journal of Sacred Lit.*, 1850.)

ANTARCTIC OCEAN, a name that should, strictly speaking, be applied only to the ice-bound sea to the south of the antarctic circle; in practice, however, it is usually vaguely extended so as to include more or less of the cold regions round the south pole, without reference to the circle. As compared with the corresponding Arctic Ocean, little is known about this portion of the earth's surface; but it is sufficiently clear that the cold and the dangers to navigation in the southern ocean greatly exceed those of the northern, and that human beings and most other animals cannot, or at least do not, ordinarily subsist within its limits. See POLAR REGIONS.

ANTELOPE. The term antelope is applied to denote a genus of *Mammalia*, included in the *Ungulate* or *Hoofed* order of that large class. Of the ungulate or hoofed mammals, the *Ruminants*, or those that "chew the cud," form a chief subdivision; and the antelopes, sheep, oxen, and goats, are included and classified together in this division as the family *Cavicornia*, or "hollow-horned" ruminants. The chief character by which the Cavicornia are distinguished from other families of the Ruminantia

consists in the peculiar and characteristic type of structure of the horns. These appendages are essentially processes of the frontal or forehead bone of the skull, and so far from being deciduous,—that is, being shed at stated periods,—as in the deer, the horns in the Cavicornia are permanent and persistent throughout life. The process arising from the frontal bone constitutes the inner shaft, or "core" of the horn; and this bony core is covered by a horny sheath. The horny sheath is purely epidermic in its origin and nature; that is, it consists of a special development of the outer skin or epidermal tissue. When these structures are contrasted with the horns of the deer,—with which group, it may be remarked, the antelopes are frequently confused, but from which they are essentially distinct,—they are at once seen to be different in every particular. The horns or "antlers" of the deer are solid, and consist entirely of bony tissue; and they are, furthermore, shed annually.

The antelopes, with the other Cavicornia, participate in the following characters, in addition to those furnished by the structure of the horns. Both sexes are generally provided with horns. The dental formula or arrangement of the teeth exhibits a want of incisor teeth in the upper, and six incisors in the lower jaw; canines totally wanting in the upper jaw, and two in the lower jaw; and twelve molars in each jaw. The dental formula, therefore, runs thus:—

$$\text{I.}\ \frac{0-0}{3-3}\ \text{C.}\ \frac{0-0}{1-1}\ \text{PM.}\ \frac{3-3}{3-3}\ \text{M.}\ \frac{3-3}{3-3}=32.$$

The feet are cleft; and accessory or supplemental hoofs exist on the back aspect of the feet.

The antelope family (*Antilopidæ*), including a great number of different species, is generally distinguished from the allied families of the sheep, oxen, and goats, by the light, graceful, and deer-like form of its members. The horns are chiefly cylindrical in shape, but may be twisted in an annular or spiral manner. The beard, or "dew-lap," characteristic of the deer tribe, is generally absent in the antelopes; and of all the Cavicornia, they constitute the only family in which the curious "tear-pits" or "lachrymal sinuses" of the eyes are found. These latter organs are small sacs situated below the eyes, and devoted to the secretion of a yellow substance of a sebaceous or waxy nature.

As regards their distribution, the antelopes are chiefly found in the eastern hemisphere, and Africa appears to be the great centre of distribution of the group. South Africa is especially rich in antelopes, and they may be regarded as representing in that continent the deer of other regions of the world. In habits they are, for the most part, gregarious, and are frequently found in immense herds inhabiting the grassy plateaus and plains; whilst some species are exclusively mountainous in their distribution.

The particular form to which the name of "antelope" has been generally assigned is the *Antilope cervicapra* (Plate I. fig. 5), found in the East, and distinguished by the triple curve of its annulated horns. The gazelle or Barbary antelope (*Gazella Dorcas*) has long been famed in the poetic imagery of Eastern writers. It has two small black horns. The algazel (*Gazella Leucoryx*) (Plate I. fig. 2), found in Persia and Arabia, has slender limbs, and the horns of the male are horizontal, bent backwards, obliquely annulated, with smooth tips, and nearly three feet long. Several nearly allied species inhabit the northern portions of Africa, the *Gazella Corinna* (Plate I. fig. 3) exemplifying one of these latter forms. The springbok (*Gazella Euchore*) of the Dutch settlers, or "springer" antelope, is a well-known form inhabiting the southern districts of Africa. The horns are simple and annulate, and are curved, so as to form a lyrate or lyre-shaped figure. This animal's activity and powers of leaping have procured for it its familiar names; and travellers have long noted the immense numbers of these forms which congregate in vast herds in the plains of Southern and Central Africa. The bontebok (*Gazella Pygarga*), and the blesbok (*Gazella albifrons*), are allied to the springbok, and inhabit the same regions as that form. The other species found in Southern Africa include the rarer blue antelope (*Gazella leucophæa*), and the roan antelope (*Gazella equina*), a large species described by Burchell.

The water bok (*Kobus ellipsiprymnus*) (Plate I. fig. 4), a well-known African form, is of considerable size. Its familiar name has been derived from its habit of frequenting rivers, and from its powers of swimming. The horns are large, curved, and spreading. The klippspringer (*Oreotragus saltatrix*) of South Africa has a close resemblance in size and habits to the European chamois. The koodoo (*Strepsiceros Koodoo*) (Plate I. fig. 1), inhabiting South and West Africa, and otherwise widely distributed over the continent, is provided with very long spiral horns, which, however, exist only in the male animals. These latter antelopes represent "solitary" species, that is, they are generally found living in detached pairs, or as solitary individuals. A related species to the koodoo has been described under the name of *Antilope Doria.*

The pigmy antelopes present examples of singular members of the family, in that they are of exceedingly diminutive size. The *Guevei* (*Antilope* [or *Cephalolophus*] *pygmæa*) presents two well-marked varieties, and one female specimen of the smaller variety scarcely exceeded the dimensions of a large rat. The gueveis occur on the Guinea Coast, but are also occasionally found at the Cape of Good Hope. The bush antelope (*Cephalolophus sylvicultrix*), inhabiting the districts around Sierra Leone, is also of a smaller size than the more typical antelopes, and is nearly related to the preceding forms. The harnessed antelope (*Antilope scripta*) (Plate II. fig. 1), so named from the white stripes with which its body is encircled, has been described as occurring in Senegal.

The eland or impophoo (*Boselaphus Oreas*) is one of the largest of the antelopes, and is ox-like in its general proportions and appearance. The horns are straight and erect, and the breast possesses a "dew-lap" or tuft. It inhabits the flat lands of Southern Africa. Allied to the elands, but of smaller size, we find the addax (*Oryx nasomaculata*). Of this species there are several varieties; but the typical form is found in Northern Africa, and is distinguished by the elongated spiral horns.

The gnus of South Africa form connecting links between the antelope and ox families, presenting characters in external aspect which separate them out as singular and somewhat abnormal forms. The gnu proper or wildebeest (*Catoblepas Gnu*) (Plate II. fig. 5), and the bastard wildebeest (*Catoblepas Gorgon*), are the two forms included in this genus. The head is bovine in its appearance, and to the ox-like head are added the mane of the horse, the limbs of the stag, and the horns of the buffalo. The horns are possessed by both sexes, and are curved from their broad bases, at first downwards and forwards, their terminal portions being directed upwards and backwards. These animals resemble a small horse in size, and occur in large herds on the flat steppes of Southern Africa, although they appear to be migratory in habits, and to have a wide range in distribution over the southern half of the continent.

Having thus indicated the more familiar of the antelopes inhabiting the great African or central tract of distribution of the family, we may next glance at the species found in the other continents. The Chinese antelope (*Antilope gutturosa*), or dzerin of the Mongolian Tartars, possesses short, thick horns, directed backwards, divergent, with their points turned inwards. It occurs in the deserts lying between China and Thibet. The chiru (*Pantholops Hodgsonii*), inhabiting Thibet and the mountainous slopes of the Himalayas, possesses elongated horns of an annulated character, and is besides distinguished by a soft glandular swelling above each nostril. It has an abundant woolly coating; and from the fact of it sometimes appearing with a single horn,—the second horn being rudimentary or undeveloped,—the mythical tales of "unicorns" are supposed to have arisen.

The chicara (*Tetracerus quadricornis*) (Plate II. fig. 4), or four-horned antelope, found in the forests of India generally, and plentifully in Bengal, is of small size, and distinguished by the presence, in the males only, of four horns, the larger pair of which are situated on the upper aspect of the forehead, and are smooth, erect, inclined slightly forwards, divergent, and about three inches long. The smaller horns are situated in front of the first pair, and average in length an inch or more. The nyl ghau (*Portax picta*) (Plate II. fig. 3), found in Northern India, like its African representative, the gnu, appears to unite in itself the characters of the antelopes and oxen. The native name of the creature, *nyl ghau*, signifies *blue ox*, and by the inhabitants of India it is regarded as being an ox, although its true place is undoubtedly among the antelopes. In size the nyl ghau resembles a stag; the tail is tufted; and the horns, occurring in the males only, are curved upwards, and diverge at their extremities. The nyl ghau is susceptible of being partly domesticated, and it has been ascertained to breed freely in a tame state.

The European species of antelope include the chamois (*Rupicapra Tragus*) (Plate II. fig. 2), and the saiga (*Colus* or *Antilocapra Saiga*). The former is essentially European in its distribution, but the latter extends from Poland and Russia into Asia. The chamois inhabits the Alps and mountains of Southern Europe, and occurs in small herds. The horns are present in both males and females, and are of small size, and recurved at their extremities. The chamois may be regarded as tending to link the antelope type to that of the sheep. The saiga is distinguished by the large size of the horns, and by the peculiar conformation of the nose, the opening of which is large, and bounded by a soft cartilaginous margin.

The American continent possesses but two representatives of the antelope family. These are the so-called Rocky Mountain sheep or goat—a true antelope—and the prongbuck or cabrit of North American regions. The Rocky Mountain sheep or goat (*Haplocerus laniger*), possessing a coat of long woolly hair, is closely related to the chamois of Europe; and in this form, as well as in the prongbuck, the connection between the antelopes and goats may be traced.

The prongbuck (*Antilocapra furcifera* or *americana*) (Plate I. fig. 6) presents a singular exception to the other members of the antelope family, in the deciduous nature of the *sheaths* of the horns, which are annually shed and developed. Accessory hoofs are wanting in the prongbuck, and the lachrymal sinuses of other antelopes are undeveloped; as also are the "inguinal pores," or groin-sacs, found in most members of the family, and which secrete a viscid substance, the function of which is undetermined. The females are devoid of horns, and those of the males are branched in front, or are "furcate,"—a conformation of these structures not found in any other member of the antelope family. The chief habitat of the prongbuck appears to be the prairie lands of Central America, and its northern limit would appear to be about the fifty-third degree of north latitude. (A. W.)

ANTEMNÆ, a small Latian town, of great antiquity, built on the top of a hill that rose above the alluvial plain at the meeting of the Anio and Tiber. Hersilia, the wife of Romulus, was a native of Antemnæ; and the city was one of those that endeavoured to avenge the rape of the Sabine women. In purely historic times it is of the smallest importance. The Samnites were pursued thither by Crassus, after the battle of the Colline Gate (82 B.C.), and surrendered there to Sulla. In 409 A.D. Alaric encamped on the hill, which now retains no trace of the ancient city.

ANTENOR, a Trojan elder of great prudence, who advised his fellow-townsmen to send Helen back to her husband, and in various ways showed himself not unfriendly to the Greeks. In the Homeric poems there is no intimation of this disposition having led him into any breach of his natural allegiance; but in the later development of the romance he appears as a full-blown traitor, and in the general sack of the city his house, distinguished by a panther's skin at the door, is spared by the victors in reward of his treachery. He afterwards, according to various versions of the legend, either rebuilt a city on the site of Troy, or settled at Cyrene, or became the founder of Padua (*Patavium*) and several other towns in Eastern Italy.

ANTENOR, son of Euphranor, the native sculptor to whom the Athenians were indebted for the bronze statues of Harmodius and Aristogiton, which, after adorning the Ceramicus, were carried off to Susa by Xerxes, and restored, it is probable, by Alexander.

ANTEQUERA, an ancient city of the province of Malaga, in Spain, supposed to be the Roman *Antiquaria*, or *Anticaria*, beautifully situated in a fertile valley on the south of the river Guadaljorce, 28 miles N. of Malaga, and 45 W. of Granada. It occupies a commanding position, while the remains of its walls, and of a fine Moorish castle on a rock that overhangs the town, show how admirably its natural defences were supplemented by art. In 1410 it was recaptured from the Moors by the regent Fernando, and thereafter became one of the most important outposts of the Christian power in Spain. Antequera possesses manufactures of flannels, paper, leather, silk, soap; it has also a large trade in grain, fruit, and oil, while marble is quarried to a considerable extent in the neighbourhood. Population, 27,201.

ANTHEM is derived from the Greek ἀντίφωνα, through the Saxon *Antefn*, and originally had the same meaning as antiphony. (See ANTIPHONY.) It is now, however, generally restricted to a form of musical composition peculiar to the service of the Church of England, and appointed by the rubrics to follow the third collect at both morning and evening prayer, "in choirs and places where they sing." Several anthems are included in the English coronation service. The words are selected from Holy Scripture, or in some cases from the Liturgy, and the music is generally more elaborate and varied than that of psalm or hymn tunes. Anthems may be written for soli voices only, for the full choir, or for both, and according to this distinction are called respectively *Verse*, *Full*, and *Full with Verse*. Though the anthem of the Church of England is analogous to the *motett* of the Roman Catholic and Lutheran Churches, both being written for a trained choir, and not for the congregation, it is as a musical form essentially English in its origin and development. The English school of musicians has from the first devoted its chief attention to this form, and scarcely a composer of any note can be named who has not written several good anthems. Tallis, Tye, Bird, and Farrant, in the 16th century; Orlando Gibbons, Blow, and Purcell, in the 17th; and Croft, Boyce, Kent, Nares, Cooke, and Samuel Arnold, in the 18th, have composed anthems which are still to be regularly heard in cathedral services.

ANTHEMIUS, a Greek mathematician and architect of great genius, who produced, under the patronage of Justinian (532 A.D.), the original and daring plans for the church of St Sophia, in Constantinople, which strikingly displayed at once his knowledge and his ignorance. He was one of five brothers—the sons of Stephanus, a physician of Tralles—who were all more or less eminent in their respective departments. Dioscorus followed his father's profession in his native place; Alexander became at Rome one of the most celebrated medical men of his time; Olympius was deeply versed in Roman jurisprudence; and Metrodorus was one of the distinguished grammarians of the great Eastern capital. There appears to be good grounds for believing that Anthemius anticipated Buffon in the invention of burning glasses; he has also been credited, though on very dubious authority, with a knowledge of gunpowder, or some similar compound, and with a certain acquaintance with the force of steam. Some portions of his περὶ παραδόξων μηχανημάτων were published by Dupuy in 1777, and also appeared, in 1786, in the forty-second volume of the *Hist. de l' Acad. des Inscr.* (See Gibbon's *Dec. and Fall,* vol. vii. cap. xl.; Procopius, *de Ædific.*)

ANTHESTERIA, an Athenian festival held annually in the month of Anthesterion, corresponding nearly to our February, at which time the wine stored at the previous vintage was considered fit for use. The object of the festival was to celebrate the arrival of that season, and the beginning of spring. It lasted three days, from the 11th to the 13th of the month. On the first day, called *Pithoigia,* or "jar opening," libations were offered from the newly-opened jars to the god of wine, all the household, including servants or slaves, joining in the festivity of the occasion. The rooms and the drinking vessels in them were adorned with spring flowers, as were also the children over three years of age. The second day, which was named *Choës,* or "the pouring," was a time of merry-making. The people dressed themselves gaily, some in the disguise of the mythical personages in the suite of Bacchus, and paid a round of visits to their acquaintances. Drinking clubs met to drink off matches, the winner being he who drained his cup most rapidly. Others did not forget deceased relations, but poured libations on their tombs. On the part of the state this day was the occasion of a peculiarly solemn and secret ceremony in one of the temples of Bacchus, which for the rest of the year was closed. The Basilissa, or Basilinna, wife of the Archon Basileus for the time, went through a ceremony of marriage to the wine god, in which she was assisted by fourteen Athenian matrons, called *Geraræ,* chosen by the Basileus, and sworn to secrecy. The third day was named χύτροι, or "jugs." Cooked fruit of all kinds was offered to Mercury, in his capacity of a god of the lower world; rejoicings and games were held; and though no tragedy was allowed to be performed in the theatre, there was yet a sort of rehearsal, at which the players for the ensuing dramatic festival were selected.

ANTHOLOGY. The term anthology, literally denoting a collection of flowers, is figuratively applied to any selection of literary beauties, and especially to that great body of fugitive poetry, comprehending about 4500 pieces, by upwards of 300 writers, which is commonly known as the GREEK ANTHOLOGY.

Literary History of the Greek Anthology.—The art of occasional poetry had been cultivated in Greece from an early period,—less, however, as the vehicle of personal feeling, than as the recognised commemoration of remarkable individuals or events, or the accompaniment of votive offerings. Such compositions were termed epigrams, *i.e.,* inscriptions. The modern use of the word is a departure from the original sense, which simply indicated that the composition was intended to be engraved or inscribed. Such a composition must necessarily be brief, and the restraints attendant upon its publication concurred with the simplicity of Greek taste in prescribing conciseness of expression, pregnancy of meaning, purity of diction, and singleness of thought as the indispensable conditions of excellence in the epigrammatic style. The term was soon extended to any piece by which these conditions were fulfilled. The transition from the monumental to the purely literary character of the epigram was favoured by the exhaustion of more lofty forms of poetry, the general increase, from the general diffusion of culture, of accomplished writers and tasteful readers, but, above all things, by the changed political circumstances of the times, which induced numbers who would otherwise have engaged in public affairs to addict themselves to literary pursuits. These causes came into full operation during the Alexandrian era, in which we find every description of epigrammatic composition perfectly developed. About 90 B.C., the sophist and poet, Meleager of Gadara, undertook to combine the choicest effusions of his predecessors into a single body of fugitive poetry. Collections of monumental inscriptions, or of poems on particular subjects, had previously been formed by Polemon the grammarian, Alcetas, and others; but Meleager first gave the principle a comprehensive application. His selection, compiled from forty-six of his predecessors, from Sappho downward, and including numerous contributions of his own, was entitled *The Garland* (Στέφανος); and in an introductory poem each poet is compared to some flower, fancifully deemed appropriate to his genius. The arrangement of the collection was alphabetical, according to the initial letter of each epigram.

In the age of Tiberius (rather than of Trajan, as commonly stated) the work of Meleager was continued by another epigrammatist, Philip of Thessalonica, who first employed the term anthology. His collection included the compositions of thirteen writers subsequent to Meleager. Somewhat later, another supplement was formed by the sophist Diogenianus, and, under Hadrian, Strato of Sardis compiled his elegant but tainted Μοῦσα παιδική from his own productions and those of earlier writers. No further collection from various sources is recorded until the time of Justinian, when epigrammatic writing, especially in its amatory department, experienced a great revival at the hands of Agathias, the historian, Paulus Silentiarius, and their circle. Their ingenious but mannered productions were collected by Agathias into a new anthology, entitled *The Circle* (Κύκλος); the first to be divided into books, and arranged with reference to the subjects of the pieces.

Five Greek anthologies, accordingly, existed at the commencement of the Middle Ages. The partial incorporation of these into a single body was the work of a certain Constantinus Cephalas, whose name alone is preserved in the single MS. of his compilation extant, but who probably lived during the temporary revival of letters under Constantine Porphyrogenitus, at the beginning of the 10th century. He appears to have merely made excerpts from the existing anthologies, with the addition of selections from Lucillius, Palladas, and other epigrammatists, whose compositions had been published separately. His arrangement, to which we shall have to recur, is founded on a principle of classification, and nearly corresponds to that adopted by Agathias. His principle of selection is unknown; it is only certain that while he omitted much that he should have retained, he has preserved much that would otherwise have perished. The extent of our obligations may be ascertained by a comparison between his anthology and that of the next editor, the monk Maximus Planudes

(1320 A.D.), who has not merely grievously mutilated the anthology of Cephalas by omissions, but has disfigured it by interpolating verses of his own. We are, however, indebted to him for the preservation of the epigrams on works of art, which seem to have been accidentally omitted from our only transcript of Cephalas.

The Planudean was the only recension of the anthology known at the revival of classical literature, and was first published at Florence, by Janus Lascaris, in 1594. It long continued to be the only accessible collection, for although the Palatine MS., the sole extant copy of the anthology of Cephalas, was discovered at Heidelberg by Salmasius in 1606, it was not published until 1772, when it was included in Brunck's *Analecta Veterum Poetarum Græcorum.* This edition was superseded by the standard one of Friedrich Jacobs (Leipsic, 1794–1803, 13 vols.), the text of which was reprinted in a more convenient form in 1813–17, and occupies three pocket volumes in the Tauchnitz series of the classics. The best edition for general purposes is perhaps that of M. Dübner in Didot's *Bibliotheca* (Paris, 1864–72), which contains the Palatine Anthology, the epigrams of the Planudean Anthology not comprised in the former, an appendix of pieces derived from other sources, copious notes selected from all quarters, a literal Latin prose translation by Boissonade, Bothe, and Lapaume, and the metrical Latin versions of Hugo Grotius. The best edition of the Planudean Anthology is the splendid one by Van Bosch and Van Lennep (Utrecht, 1795–1822). Welcker, Meineke, and other German scholars have written valuable monographs on the Anthology.

Arrangement of the Anthology.—The Palatine MS., the archetype of the present text, was transcribed by different persons at different times, and the actual arrangement of the collection does not correspond with that signalised in the index. It is as follows:—Book 1. Christian epigrams; 2. Christodorus's description of certain statues, 3. Inscriptions in the temple at Cyzicus; 4. The prefaces of Meleager, Philip, and Agathias to their respective collections; 5. Amatory epigrams; 6. Votive inscriptions; 7. Epitaphs; 8. The epigrams of Gregory of Nazianzus; 9. Rhetorical and illustrative epigrams; 10. Ethical pieces; 11. Humorous and convivial; 12. Strato's Μοῦσα παιδική; 13. Metrical curiosities; 14. Puzzles, enigmas, oracles; 15. Miscellanies. The epigrams on works of art, as already stated, are missing from the *Codex Palatinus,* and must be sought in an appendix of epigrams only occurring in the Planudean Anthology. The epigrams hitherto recovered from ancient monuments and similar sources form another appendix in the second volume of Dübner's edition.

Style and Value of the Anthology.—One of the principal claims of the Anthology to attention is derived from its continuity, its existence as a living and growing body of poetry throughout all the vicissitudes of Greek civilisation. More ambitious descriptions of composition speedily ran their course, and having attained their complete development became extinct, or at best lingered only in feeble or conventional imitations. The humbler strains of the epigrammatic muse, on the other hand, remained ever fresh and animated, ever in intimate union with the spirit of the generation that gave them birth. To peruse the entire collection, accordingly, is as it were to assist at the disinterment of an ancient city, where generation has succeeded generation on the same site, and each stratum of soil enshrines the vestiges of a distinct epoch, but where all epochs, nevertheless, combine to constitute an organic whole, and the transition from one to the other is hardly perceptible. Four stages may be indicated:—1. The Hellenic proper, of which Simonides is the characteristic representative. This is characterised by a simple dignity of phrase, which to a modern taste almost verges upon baldness, by a crystalline transparency of diction, and by an absolute fidelity to the original conception of the epigram. Nearly all the pieces of this era are actual *bona fide* inscriptions, or addresses to real personages, whether living or deceased; narratives, literary exercises, and sports of fancy are exceedingly rare. 2. The epigram received a great development in its second or Alexandrian era, when its range was so extended as to include anecdote, satire, and amorous longing; when epitaphs and votive inscriptions were composed on imaginary persons and things, and men of taste successively attempted the same subjects in mutual emulation, or sat down to compose verses as displays of their ingenuity. The result was a great gain in richness of style and general interest, counterbalanced by a falling off in purity of diction and sincerity of treatment. The modification,—a perfectly legitimate one, the resources of the old style being exhausted,—had its real source in the transformation of political life, but may be said to commence with and to find its best representative in the playful and elegant Leonidas of Tarentum, a contemporary of Pyrrhus, and to close with Antipater of Sidon, about 140 B.C. It should be noticed, however, that Callimachus, one of the most distinguished of the Alexandrian poets, affects the sternest simplicity in his epigrams, and copies the austerity of Simonides with as much success as an imitator can expect. 3. By a slight additional modification in the same direction, the Alexandrian passes into what, for the sake of preserving the parallelism with the eras of Greek prose literature, we may call the Roman style, although the peculiarities of its principal representative are decidedly Oriental. Meleager of Gadara was a Syrian; his taste was less severe, and his temperament more fervent than those of his Greek predecessors; his pieces are usually erotic, and their glowing imagery sometimes reminds us of the Song of Solomon. The luxuriance of his fancy occasionally betrays him into far-fetched conceits, and the lavishness of his epithets is only redeemed by their exquisite felicity. Yet his effusions are manifestly the offspring of genuine feeling, and his epitaph on himself indicates a great advance on the exclusiveness of antique Greek patriotism, and is perhaps the first clear enunciation of the spirit of universal humanity characteristic of the later Stoical philosophy. With respect to his more strictly poetical qualities, Mr Symonds does not overpraise him when he says "his poetry has the sweetness and the splendour of the rose, the rapture and full throated melody of the nightingale." His gaiety and licentiousness are imitated and exaggerated by his somewhat later contemporary, the Epicurean Philodemus, perhaps the liveliest of any of the epigrammatists; his fancy reappears with diminished brilliancy in Philodemus's contemporary, Zonas, in Crinagoras, who wrote under Augustus, and in Marcus Argentarius, of uncertain date; his peculiar gorgeousness of colouring remains entirely his own. At a later period of the empire another *genre,* hitherto comparatively in abeyance, was developed, the satirical. Lucillius, who flourished under Nero, and Lucian, more renowned in other fields of literature, display a remarkable talent for shrewd, caustic epigram, frequently embodying moral reflections of great cogency, often lashing vice and folly with signal effect, but not seldom indulging in mere trivialities, or deformed by scoffs at personal blemishes. This style of composition is not properly Greek, but Roman; it answers to the modern definition of epigram, and has hence attained a celebrity in excess of its deserts. It is remarkable, however, as an almost solitary example of direct Latin influence on Greek literature. The same style obtains with Palladas, an Alexandrian grammarian of the 4th century, the last of the strictly classical epigrammatists, and the first to be guilty of downright bad taste. His better pieces, however, are characterised by an austere ethical impressiveness, and his literary position is very interesting, as that of an indignant but despairing opponent of Christianity. 4. The fourth or Byzantine style of epigrammatic composition was cultivated by the *beaux-esprits* of the court of Justinian. To a great extent this is merely imitative, but the circumstances of the period operated so as to produce a species of originality. The peculiarly ornate and *recherché* diction of Agathias and his compeers is not a merit in itself, but applied for the first time, it has the effect of revivifying an old form, and many of their new locutions are actual enrichments of the language. The writers, moreover, were men of genuine poetical feeling, ingenious in invention, and capable of expressing emotion with energy and liveliness; the colouring of their pieces is sometimes highly dramatic. The charge of impurity, alleged by Mr Symonds against them as a body, applies to Rufinus alone in any considerable degree, and he is purity itself compared with Martial. There is something very touching in the attitude of these last belated stragglers towards the antique culture from which they are hopelessly severed,—their half-conscious yearning for the glorious past, whose monuments still surrounded them on every side, but whose spirit had departed for ever. With them the volume of the Greek anthology is closed, for the "Christian epigrams" are totally valueless in a literary point of view.

It would be hard to exaggerate the substantial value of the Anthology, whether as a storehouse of facts bearing on antique manners, customs, and ideas, or as one among the influences which have contributed to mould the literature of the modern world. The multitudinous votive inscriptions, serious and sportive, connote the phases of Greek religious sentiment, from pious awe to irreverent familiarity and sarcastic scepticism; the moral tone of the nation at various periods is mirrored with corresponding fidelity; the sepulchral inscriptions admit us into the inmost sanctuary of family affection, and reveal a depth and tenderness of feeling beyond the province of the historian to depict, and which we should not have surmised even from the dramatists; the general tendency of the collection is to display antiquity on its most human side, and to mitigate those contrasts with the modern world which more ambitious modes of composition force into relief. The constant reference to the details of private life renders the Anthology an inexhaustible treasury for the student of archæology; art, industry, and costume receive their fullest illustration from its pages. Its influence on European literatures will be appreciated in proportion to the inquirer's knowledge of each. The further his researches extend, the greater will be his astonishment at the extent to which the Anthology has been laid under contribution for thoughts which have become household words in all cultivated languages, and at the beneficial effect of the imitation of its brevity, simplicity, and absolute verbal accuracy upon the undisciplined luxuriance of modern genius.

Translations, Imitations, &c., of the Anthology.—The best versions of the Anthology ever made are the Latin renderings of select epigrams by Hugo Grotius. They have not been printed separately, but will be found in Bosch and Lennep's edition of the Planudean *Anthology*, in the Didot edition, and in Dr Wellesley's *Anthologia Polyglotta*. The number of more or less professed imitations in modern languages is infinite, that of actual translations less considerable. French and Italian, indeed, are ill adapted to this purpose, from their incapacity of approximating to the form of the original, and their poets have usually contented themselves with paraphrases or imitations, often exceedingly felicitous. Dehesme's French prose translation, however (1863), is most excellent and valuable. The German language alone admits of the preservation of the original metre,—a circumstance advantageous to the German translators, Herder and Jacobs, who have not, however, compensated the loss inevitably consequent upon a change of idiom by any added beauties of their own. Though unfitted to reproduce the precise form, the English language, from its superior terseness, is better adapted to preserve the spirit of the original than the German; and the comparative ill success of many English translators must be chiefly attributed to the extremely low standard of fidelity and brevity observed by them. Bland, Merivale, and their associates (1806–13), are often intolerably diffuse and feeble, from want, not of ability, but of painstaking. Archdeacon Wrangham's too rare versions are much more spirited; and John Sterling's translations of the inscriptions of Simonides deserve high praise. Professor Wilson (*Blackwood's Magazine*, 1833–35), collected and commented upon the labours of these and other translators, with his accustomed critical insight and exuberant geniality, but damaged his essay by burdening it with the indifferent attempts of William Hay. In 1849 Dr Wellesley, principal of New Inn Hall, Oxford, published his *Anthologia Polyglotta*, a most valuable collection of the best translations and imitations in all languages, with the original text. In this appeared some admirable versions by Mr Goldwin Smith and Dean Merivale, which, with the other English renderings extant at the time, will be found accompanying the literal prose translation of the *Public School Selections*, executed by the Rev. George Burges for Bohn's Classical Library (1854). This is a useful volume, but the editor's notes are worthless. In 1864 Major R. G. Macgregor published an almost complete translation of the Anthology, a work of stupendous industry and fidelity, which almost redeem the general mediocrity of the execution. *Idylls and Epigrams*, by R. Garnett (1869), include about 140 translations or imitations, with some original compositions in the same style. An agreeable little volume on the Anthology, by Lord Neaves, is one of Collins's series of *Ancient Classics for Modern Readers*. Two recent critical contributions to the subject should be noticed, the Rev. James Davies's essay on Epigrams, in the *Quarterly Review* (vol. cxvii.), especially valuable for its lucid illustration of the distinction between Greek and Latin epigram; and the brilliant disquisition in Mr J. A. Symonds's *Studies of the Greek Poets* (1873).

The LATIN ANTHOLOGY is the appellation bestowed upon a collection of fugitive Latin verse, from the age of Ennius to about 1000 A.D., formed by Peter Burmann the Younger. Nothing corresponding to the Greek anthology is known to have existed among the Romans, though professional epigrammatists like Martial published their volumes on their own account, and detached sayings were excerpted from such sententious authors as Publius Syrus, while the *Priapeia* were probably but one among many collections on special subjects. The first general collection of scattered pieces made by a modern scholar was Scaliger's, in 1573, succeeded by the more ample one of Pithœus, in 1594. Numerous additions, principally from inscriptions, continued to be made, and in 1759 Burmann digested the whole into his *Anthologia veterum Latinorum Epigrammatum et Poematum*. This, occasionally reprinted, has been the standard edition until recently; but in 1869 Alexander Riese commenced a new and more critical recension, from which many pieces improperly inserted by Burmann are rejected, and his classified arrangement is discarded for one according to the sources whence the poems have been derived. The first volume contains those found in MSS., in the order of the importance of these documents; those furnished by inscriptions are to follow. Being formed by scholars actuated by no æsthetic principles of selection, but solely intent on preserving everything they could find, the Latin anthology is much more heterogeneous than the Greek, and unspeakably inferior. The really beautiful poems of Petronius and Apuleius are more properly inserted in the collected editions of their writings, and more than half the remainder consists of the frigid conceits or pedantic professional exercises of grammarians of a very late period of the empire, relieved by an occasional gem, such as the apostrophe of the dying Hadrian to his spirit, or the epithalamium of Gallienus. The collection is also, for the most part, too recent in date, and too exclusively literary in character, to add much to our knowledge of classical antiquity. The epitaphs are interesting, but the genuineness of many of them is very questionable. (R. G.)

ANTHON, Charles, an American philologist and professor of classics, was born in New York city in 1797, and died there 29th July 1867. After graduating with honours at Columbia College in 1815, he commenced the study of law, and in 1819 was admitted to the bar. But in 1820 he was appointed assistant professor of languages in his alma mater, and he thenceforth devoted himself solely to classical literature. Soon after he commenced his well-known editions of the classics, the best known being that of the *Poems* of Horace, with extensive notes and comments, published in 1830. In the latter year he was made rector of the grammar school attached to his college, and in 1835 he succeeded to the chair of Professor Morse.

ANTHONY, Saint, the founder of monasticism, was born at the village of Coma in Egypt 251 A.D. Inheriting a large fortune, he thought it his duty to distribute it among his neighbours and the poor, and to live a rigidly ascetic life. He spent several years in solitude, where according to tradition he was sorely tempted by the devil. Many disciples flocked to his retreat at Fayoom, and built their cells around his, thus forming the earliest monastic community. (See Abbey.) Anthony visited Alexandria when upwards of a hundred years old, and took an important part in the controversy with the Arians,—a fact to which we are probably indebted for the record of the life of the saint written by Athanasius. Soon after returning to his cell he died (356 A.D.), his last injunction being that the place of his burial should be kept secret. Seven Latin translations of his letters are extant in the *Bibliotheca Patrum*. Many miracles were believed to have been wrought by his intervention, among others, the cure of what was called the "sacred fire," and afterwards "St Anthony's fire" (Erysipelas). For this reason he is usually represented with a fire by his side, as typical of the inflammatory disease which he was supposed to relieve. The festival of Saint Anthony is observed on the 17th of January, under which date the *Acta Sanctorum* of the Bollandists contains a Latin translation of Athanasius's life of the saint, and other documents giving an account of his miracles. The events of his life—in particular his temptation by the devil and his meeting with St Paul—form the subjects of celebrated pictures by Caracci, Guido, Velasquez, and others. For further details of Anthony's connection with the monastic system, see Monasticism.

ANTHRACITE, Stone Coal, Kilkenny Coal, or Culm, is a variety of coal differing from the common or bituminous kind in containing a larger proportion of carbon in its composition; that element being present in anthracite to the extent of from 90 to 95 per cent. of its entire mass, while the carbon in bituminous coal usually varies from 75 to 90 per cent. Anthracite is further distinguished by its compactness, high specific gravity, bright lustre, which is frequently iridescent on the natural surfaces, and its conchoidal fracture. It does not soil the fingers when handled, like ordinary coal; it ignites with difficulty, and burns with a feeble, smokeless flame, giving out an intense heat. No sharply defined line of demarcation can be drawn between anthracite and the bituminous varieties of coal, as the one series merges by imperceptible degrees into the other. This gradation is observable in the coal deposits themselves, anthracite and bituminous coal being frequently found not far removed in different parts of the same seam, and the gradual transformation from a flaming coal to a compact, lustrous, non-flaming kind, being easily traceable. Anthracite has been defined as "the ultimate product of the conversion of vegetable matter into coal;" and the following table, drawn up by Dr Percy (*Manual of Metallurgy*), may be taken as indicating the successive stages in the process. In this table the carbon is stated at a constant standard of 100, in order better to exhibit the comparative quantities of the other elements which enter into the composition of the bodies named:—

	Carbon.	Hydrogen.	Oxygen.
1. Wood (mean of 26 analyses)	100	12·18	83·07
2. Peat	100	9·85	55·67
3. Lignite (average of 15 varieties).....	100	8·37	42·42
4. Ten Yard Coal, South Staffordshire	100	6·12	21·23
5. Steam Coal, from the Tyne...........	100	5·91	18·32
6. Pentrefelin Coal of South Wales ...	100	4·75	5·28
7. Anthracite of Pennsylvania, U.S. ...	100	2·84	1·74

The chief deposits of anthracite in Great Britain exist in the great coal-field of South Wales. They extend principally along the north side of the coal basin; and on its western limit, in Pembrokeshire, the coal is entirely anthracitic. Professor Warrington Smyth remarks, on the disposition of the deposits in South Wales:—"Even within the distance of a few hundred yards the Llanelly beds are seen to be bituminous where they rise to the south, and anthracitic in the opposite side of the trough." In the neighbourhood of Bideford, in North Devonshire, a series of thin seams of an impure, clayey anthracite are worked, to which properly the name *culm* ought to be restricted, although the whole of the anthracite exported from this country appears under that designation in the Board of Trade returns. The very meagre coal-bearing strata of Ireland yield anthracite almost exclusively. The name Kilkenny coal is given to anthracite, because that county is the centre of the South Irish coal-field, which yields no bituminous coal whatever. In the limited patches of coal found in the north of Ireland, however, some bituminous seams occur associated with anthracite. On the European continent anthracite is generally found accompanying the deposits of bituminous coal. In Belgium and Westphalia the lowest or oldest deposits of the series are anthracitic, while in Rhenish Bavaria it is the upper beds which are "dry," or least bituminous. In North America, where enormous stores of coal exist, anthracite is found in due proportion, the deposits in Pennsylvania being the richest known. The late Professor H. D. Rogers pointed out an interesting relation between the contortion or disturbance of strata in the Appalachian coal-field and the amount of bituminous matter the coal contains. In the western extension of the coal-field, where the beds are horizontal and undisturbed, the seams are highly bituminous; and in proportion as disturbance increases, the volatile compounds decrease, till on its eastern limit, in the Appalachian chain, enormous seams of a compact, pure anthracite are developed. Anthracite is used for iron-smelting and in other metallurgical operations, for lime-burning, for heating kilns, and other purposes requiring a steady, smokeless heat. As it burns with an intense concentrated heat, it is not so suitable for steam boilers as ordinary flaming coal, and the difficulty with which it ignites, as well as its disagreeable decrepitation, renders it less eligible for household purposes.

ANTHROPOLOGY

Definition and objects of the science.

ANTHROPOLOGY (the *science of man*, ἄνθρωπος, λόγος) denotes the natural history of mankind. In the general classification of knowledge it stands as the highest section of zoology or the science of animals, itself the highest section of biology or the science of living beings. To anthropology contribute various sciences, which hold their own independent places in the field of knowledge. Thus anatomy and physiology display the structure and functions of the human body, while psychology investigates the operations of the human mind. Philology deals with the general principles of language, as well as with the relations between the languages of particular races and nations. Ethics or moral science treats of man's duty or rules of conduct toward his fellow-men. Lastly, under the names of sociology and the science of culture, are considered the origin and development of arts and sciences, opinions, beliefs, customs, laws, and institutions generally among mankind, their course in time being partly marked out by the direct record of history, while beyond the historical limit our information is continued by inferences from relics of early ages and remote districts, to interpret which is the task of præ-historic archæology and geology. Not only are these various sciences concerned largely with man, but several among them have in fact suffered by the almost entire exclusion of other animals from their scheme. It is undoubted that comparative anatomy and physiology, by treating the human species as one member of a long series of related organisms, have gained a higher and more perfect understanding of man himself and his place in the universe than could have been gained by the narrower investigation of his species by and for itself. It is to be regretted that hitherto certain other sciences—psychology, ethics, and even philology and sociology—have so little followed so profitable an example. No doubt the phenomena of intellect appear in vastly higher and more complete organisation in man than in beings below him in the scale of nature, that beasts and birds only attain to language in its lower rudiments, and that only the germs of moral tendency and social law are discernible among the lower animals. Yet though the mental and moral interval between man and the nearest animals may be vast, the break is not absolute, and the investigation of the laws of reason and instinct throughout the zoological system, which is already casting some scattered rays of light on the study of man's highest organisation, may be destined henceforth to throw brighter illumination into its very recesses. Now this condition of things, as well as the accepted order in which the sciences have arranged themselves by their mode of growth, make it desirable that anthropology should not too ambitiously strive to include within itself the sciences which provide so much of its wealth, but that each science should pursue its own subject through the whole range of living beings, rendering to anthropology an account of so much of its results as concerns man. Such results it is the office of anthropology to collect and co-ordinate, so as to elaborate as completely as may be the synopsis of man's bodily and mental nature, and the theory of his whole course of life and action from his first appearance on earth. As will be seen from the following brief summary, the information to be thus brought together from contributing sciences is widely different both in accuracy and in soundness. While much of the descriptive detail is already clear and well filled in, the general principles of its order are still but vaguely to be discerned, and as our view quits the comparatively distinct region near ourselves, the prospect fades more and more into the dimness of conjecture.

Relation of Man to the lower animals.

I. *Man's Place in Nature.*—It is now more than thirty years since Dr Prichard, who perhaps of all others merits the title of founder of modern anthropology, stated in the following forcible passage, which opens his *Natural History of Man*, the closeness of man's physical relation to the lower animals:—

"The organised world presents no contrasts and resemblances more remarkable than those which we discover on comparing mankind with the inferior tribes. That creatures should exist so nearly approaching to each other in all the particulars of their physical structure, and yet differing so immeasurably in their endowments and capabilities, would be a fact hard to believe, if it were not manifest to our observation. The differences are everywhere striking: the resemblances are less obvious in the fulness of their extent, and they are never contemplated without wonder by those who, in the study of anatomy and physiology, are first made aware how near is man in his physical constitution to the brutes. In all the principles of his internal structure, in the composition and functions of his parts, man is but an animal. The lord of the earth, who contemplates the eternal order of the universe, and aspires to communion with its invisible Maker, is a being composed of the same materials, and framed on the same principles, as the creatures which he has tamed to be the servile instruments of his will, or slays for his daily food. The points of resemblance are innumerable; they extend to the most recondite arrangements of that mechanism which maintains instrumentally the physical life of the body, which brings forward its early development and admits, after a given period, its decay, and by means of which is prepared a succession of similar beings destined to perpetuate the race."

Referring the reader to the articles HISTOLOGY and PHYSIOLOGY for evidence of the similarity of minute organisation both in structure and function, through the range of animal life upward to man, and to the article ANIMAL KINGDOM for the general classification of the series of invertebrate and vertebrate animals, we have here to show in outline the relations between man and the species most closely approaching him. It is admitted that the higher apes come nearest to man in bodily formation, and that it is essential to determine their zoological resemblances and differences as a step toward ascertaining their absolute relation in nature. "At this point," writes Professor Owen in a paper on the "Osteology of the Apes," "every deviation from the human structure indicates with precision its real peculiarities, and we then possess the true means of appreciating those modifications by which a material organism is especially adapted to become the seat and instrument of a rational and responsible soul." (On the "Osteology of the Chimpanzee and Orang Utan," in *Proc. Zool. Soc.*, vol. i.) Professor Huxley, in his *Man's Place in Nature* (London 1863), comparing man with order after order of the mammalia, decides "There would remain then but one order for comparison, that of the Apes (using that word in its broadest sense), and the question for discussion would narrow itself to this—is Man so different from any of these Apes that he must form an order by himself? Or does he differ less from them than they differ from one another, and hence must take his place in the same order with them?" This anatomist states the anatomical relations between man and ape in untechnical terms suited to the present purpose, and which would be in great measure accepted by zoologists and anthropologists, whether agreeing or not with his ulterior views. The relations are most readily stated in comparison with the gorilla, as on the whole the most anthropomorphous ape. In the general proportions of the body and limbs there is a marked difference between the gorilla and man, which at once strikes the eye. The gorilla's brain-case is smaller, its trunk larger, its lower limbs shorter, its upper limbs longer in proportion than those of man. The differences between a gorilla's skull and a man's are truly immense. In the gorilla, the face,

Apes and Man.

formed largely by the massive jaw-bones, predominates over the brain-case or cranium; in the man these proportions are reversed. In man the occipital foramen, through which passes the spinal cord, is placed just behind the centre of the base of the skull, which is thus evenly balanced in the erect posture, whereas the gorilla, which goes habitually on all fours, and whose skull is inclined forward, in accordance with this posture has the foramen further back. In man the surface of the skull is comparatively smooth, and the brow-ridges project but little, while in the gorilla these ridges overhang the cavernous orbits like penthouse roofs. The absolute capacity of the cranium of the gorilla is far less than that of man; the smallest adult human cranium hardly measuring less than 63 cubic inches, while the largest gorilla cranium measured had a content of only 34½ cubic inches. The large proportional size of the facial bones, and the great projection of the jaws, confer on the gorilla's skull its small facial angle and brutal character, while its teeth differ from man's in relative size and number of fangs. Comparing the lengths of the extremities, it is seen that the gorilla's arm is of enormous length, in fact about one-sixth longer than the spine, whereas a man's arm is one-fifth shorter than the spine; both hand and foot are proportionally much longer in the gorilla than in man; the leg does not so much differ. The vertebral column of the gorilla differs from that of man in its curvature and other characters, as also does the conformation of its narrow pelvis. The hand of the gorilla corresponds essentially as to bones and muscles with that of man, but is clumsier and heavier; its thumb is "opposable" like a human thumb, that is, it can easily meet with its extremity the extremities of the other fingers, thus possessing a character which does much to make the human hand so admirable an instrument; but the gorilla's thumb is proportionately shorter than man's. The foot of the higher apes, though often spoken of as a hand, is anatomically not such, but a prehensile foot. It is argued by Professor Owen and others that the position of the great toe converts the foot of the higher apes into a hand, an extremely important distinction from man; but against this Professor Huxley maintains that it has the characteristic structure of a foot, with a very movable great toe. The external unlikeness of the apes to man depends much on their hairiness, but this and some other characteristics have no great zoological value. No doubt the difference between man and the apes depends, of all things, on the relative size and organisation of the brain. While similar as to their general arrangement to the human brain, those of the higher apes, such as the chimpanzee, are much less complex in their convolutions, as well as much less both in absolute and relative weight—the weight of a gorilla's brain hardly exceeding 20 ounces, and a man's brain hardly weighing less than 32 ounces, although the gorilla is considerably the larger animal of the two.

Zoological classification.

These anatomical distinctions are undoubtedly of great moment, and it is an interesting question whether they suffice to place man in a zoological order by himself. It is plain that some eminent zoologists, regarding man as absolutely differing as to mind and spirit from any other animal, have had their discrimination of mere bodily differences unconsciously sharpened, and have been led to give differences, such as in the brain or even the foot of the apes and man, somewhat more importance than if they had merely distinguished two species of apes. Among the present generation of naturalists, however, there is an evident tendency to fall in with the opinion, that the anatomical differences which separate the gorilla or chimpanzee from man are in some respects less than those which separate these man-like apes from apes lower in the scale. Yet naturalists agree to class both the higher and lower apes in the same order. This is Professor Huxley's argument, some prominent points of which are the following:—As regards the proportion of limbs, the hylobates or gibbon is as much longer in the arms than the gorilla as the gorilla is than the man, while on the other hand, it is as much longer in the legs than the man as the man is than the gorilla. As to the vertebral column and pelvis, the lower apes differ from the gorilla as much as, or more than, it differs from man. As to the capacity of the cranium, men differ from one another so extremely that the largest known human skull holds nearly twice the measure of the smallest, a larger proportion than that in which man surpasses the gorilla; while, with proper allowance for difference of size of the various species, it appears that some of the lower apes fall nearly as much below the higher apes. The projection of the muzzle, which gives the character of brutality to the gorilla as distinguished from the man, is yet further exaggerated in the lemurs, as is also the backward position of the occipital foramen. In characters of such importance as the structure of the hand and foot, the lower apes diverge extremely from the gorilla; thus the thumb ceases to be opposable in the American monkeys, and in the marmosets is directed forwards, and armed with a curved claw like the other digits, the great toe in these latter being insignificant in proportion. The same argument can be extended to other points of anatomical structure, and, what is of more consequence, it appears true of the brain. A series of the apes, arranged from lower to higher orders, shows gradations from a brain little higher than that of a rat, to a brain like a small and imperfect imitation of a man's; and the greatest structural break in the series lies not between man and the man-like apes, but between the apes and monkeys on one side, and the lemurs on the other. On these grounds Professor Huxley, restoring in principle the Linnean classification, desires to include man in the order of *Primates*. This order he divides into seven families: first, the *Anthropini*, consisting of man only; second, the *Catarhini*, or Old World apes; third, the *Platyrhini*, all New World apes, except the marmosets; fourth, the *Arctopithecini*, or marmosets; fifth, the *Lemurini*, or lemurs; sixth and seventh, the *Cheiromyini* and *Galeopithecini*. It seems likely that, so far as naturalists are disposed to class man with other animals on purely zoological grounds, some such classification as this may, in the present state of comparative anatomy, be generally adopted.

Psychological classification.

It is in assigning to man his place in nature on psychological grounds that the greater difficulty comes into view. The same naturalist, whose argument has just been summarised against an absolute structural line of demarcation between man and the creatures next in the scale, readily acknowledges an immeasurable and practically infinite divergence, ending in the present enormous gulf between the family of apes and the family of man. To account for this intellectual chasm as possibly due to some minor structural difference, is, however, a view strongly opposed to the prevailing judgment. The opinion is deeply rooted in modern as in ancient thought, that only a distinctively human element of the highest import can account for the severance between man and the highest animal below him.

Bodily structure.

Differences in the mechanical organs, such as the perfection of the human hand as an instrument, or the adaptability of the human voice to the expression of human thought, are indeed of great value. But they have not of themselves such value, that to endow an ape with the hand and vocal organs of a man would be likely to raise it through any large part of the interval that now separates it from humanity. Much more is to be said for the view that man's larger and more highly organised brain accounts for those mental powers in which he so absolutely surpasses the brutes

Senses. The distinction does not seem to lie principally in the range and delicacy of direct sensation, as may be judged from such well-known facts as man's inferiority to the eagle in sight, or to the dog in scent. At the same time, it seems that the human sensory organs may have in various respects acuteness beyond those of other creatures.

Mental powers. But, beyond a doubt, man possesses, and in some way possesses by virtue of his superior brain, a power of co-ordinating the impressions of his senses, which enables him to understand the world he lives in, and by understanding to use, resist, and even in a measure rule it. No human art shows the nature of this human attribute more clearly than does language. Man shares with the mammalia and birds the direct expression of the feelings by emotional tones and interjectional cries; the parrot's power of articulate utterance almost equals his own; and, by association of ideas in some measure, some of the lower animals have even learnt to recognise words he utters. But, to use words in themselves unmeaning, as symbols by which to conduct and convey the complex intellectual processes in which mental conceptions are suggested, compared, combined, and even analysed, and new ones created—this is a faculty which is scarcely to be traced in any lower animal. The view that this, with other mental processes, is a function of the brain, is remarkably corroborated by modern investigation of the disease of aphasia, where the power of thinking remains, but the power is lost of recalling the word corresponding to the thought, and this mental defect is found to accompany a diseased state of a particular locality of the brain (see APHASIA). This may stand among the most perfect of the many evidences that, in Professor Bain's words, "the brain is the principal, though not the sole organ of mind." As the brains of vertebrate animals form an ascending scale, more and more approaching man's in their arrangement, the fact here finds its explanation, that lower animals perform mental processes corresponding in their nature to our own, though of generally less power and complexity. The full evidence of this correspondence will be found in such works as Brehm's *Thierleben*; and some of the salient points are set forth by Mr Darwin, in the chapter on "Mental Powers," in his *Descent of Man.* Such are the similar effects of terror on man and the lower animals, causing the muscles to tremble, the heart to palpitate, the sphincters to be relaxed, and the hair to stand on end. The phenomena of memory, both as to persons and places, is strong in animals, as is manifest by their recognition of their masters, and their returning at once to habits disused for many years, but of which their brain has not lost the stored-up impressions. Such facts as that dogs "hunt in dreams," make it likely that their minds are not only sensible to actual events, present and past, but can, like our minds, combine revived sensations into ideal scenes in which they are actors,—that is to say, they have the faculty of imagination. As for the reasoning powers in animals, the accounts of monkeys learning by experience to break eggs carefully, and pick off bits of shell, so as not to lose the contents, or of the way in which rats or martens after a while can no longer be caught by the same kind of trap, with innumerable similar facts, show in the plainest way that the reason of animals goes so far as to form by new experience a new hypothesis of cause and effect which will henceforth guide their actions. The employment of mechanical instruments, of which instances of monkeys using sticks and stones, and some other similar cases, furnish the only rudimentary traces among the lower animals, is one of the often quoted distinctive powers of man. With this comes the whole vast and ever-widening range of inventive and adaptive art, where the uniform hereditary instinct of the cell-forming bee and the nest-building bird are supplanted by multiform processes and constructions, often at first rude and clumsy in comparison to those of the lower instinct, but carried on by the faculty of improvement and new invention into ever higher stages. "From the moment," writes Mr Wallace (*Natural Selection*, p. 325), "when the first skin was used as a covering, when the first rude spear was formed to assist in the chase, when fire was first used to cook his food, when the first seed was sown or shoot planted, a grand revolution was effected in nature, a revolution which in all the previous ages of the earth's history had had no parallel; for a being had arisen who was no longer necessarily subject to change with the changing universe,—a being who was in some degree superior to nature, inasmuch as he knew how to control and regulate her action, and could keep himself in harmony with her, not by a change in body, but by an advance of mind."

As to the lower instincts tending directly to self-preservation, it is acknowledged on all hands that man has them in a less developed state than other animals; in fact, the natural defencelessness of the human being, and the long-continued care and teaching of the young by the elders, are among the commonest themes of moral discourse. Parental tenderness and care for the young are strongly marked among the lower animals, though so inferior in scope and duration to the human qualities; and the same may be said of the mutual forbearance and defence which bind together in a rudimentary social bond the families and herds of animals. Philosophy seeking knowledge for its own sake; morality, manifested in the sense of truth, right, and virtue; and religion, the belief in and communion with superhuman powers ruling and pervading the universe, are human characters, of which it is instructive to trace, if possible, the earliest symptoms in the lower animals, but which can there show at most only faint and rudimentary signs of their wondrous development in mankind. That the tracing of physical and even intellectual continuity between the lower animals and our own race, does not necessarily lead the anthropologist to lower the rank of man in the scale of nature, cannot be better shown than by citing one of the authors of the development theory, Mr A. R. Wallace (*op. cit.*, p. 324). Man, he considers, is to be placed "apart, as not only the head and culminating point of the grand series of organic nature, but as in some degree a new and distinct order of being."

Materialistic and spiritualistic theories. To regard the intellectual functions of the brain and nervous system as alone to be considered in the psychological comparison of man with the lower animals, is a view satisfactory to those thinkers who hold materialistic views. According to this school, man is a machine, no doubt the most complex and wonderfully adapted of all known machines, but still neither more nor less than an instrument whose energy is provided by force from without, and which, when set in action, performs the various operations for which its structure fits it, namely, to live, move, feel, and think. This doctrine, which may be followed up from Descartes's theory of animal life into the systems of modern writers of the school of Moleschott and Büchner, underlies the *Lectures on Man* of Professor Carl Vogt, one of the ablest of modern anthropologists (English translation published by Anthropological Society, London, 1864). Such views, however, always have been and are strongly opposed by those who accept on theological grounds a spiritualistic doctrine, or what is, perhaps, more usual, a theory which combines spiritualism and materialism in the doctrine of a composite nature in man, animal as to the body and in some measure as to the mind, spiritual as to the soul. It may be useful, as an illustration of one opinion on this subject, to continue here from an earlier page the citation of Dr Prichard's comparison between man and the lower animals:—

"If it be inquired in what the still more remarkable difference consists, it is by no means easy to reply. By some it will be said that man, while similar in the organisation of his body to the lower tribes, is distinguished from them by the possession of an immaterial soul, a principle capable of conscious feeling, of intellect and thought. To many persons it will appear paradoxical to ascribe the endowment of a soul to the inferior tribes in the creation, yet it is difficult to discover a valid argument that limits the possession of an immaterial principle to man. The phenomena of feeling, of desire and aversion, of love and hatred, of fear and revenge, and the perception of external relations manifested in the life of brutes, imply, not only through the analogy which they display to the human faculties, but likewise from all that we can learn or conjecture of their particular nature, the superadded existence of a principle distinct from the mere mechanism of material bodies. That such a principle must exist in all beings capable of sensation, or of anything analogous to human passions and feelings, will hardly be denied by those who perceive the force of arguments which metaphysically demonstrate the immaterial nature of the mind. There may be no rational grounds for the ancient dogma that the souls of the lower animals were imperishable, like the soul of man: this is, however, a problem which we are not called upon to discuss; and we may venture to conjecture that there may be immaterial essences of divers kinds, and endowed with various attributes and capabilities. But the real nature of these unseen principles eludes our research: they are only known to us by their external manifestations. These manifestations are the various powers and capabilities, or rather the habitudes of action, which characterise the different orders of being, diversified according to their several destinations."

Dr Prichard here puts forward distinctly the time-honoured doctrine which refers the mental faculties to the operation of the soul. The view maintained by a distinguished comparative anatomist, Professor Mivart, in his *Genesis of Species*, ch. xii., may fairly follow. "Man, according to the old scholastic definition, is 'a rational animal' (*animal rationale*), and his animality is distinct in nature from his rationality, though inseparably joined, during life, in one common personality. Man's animal body must have had a different source from that of the spiritual soul which informs it, owing to the distinctness of the two orders to which those two existences severally belong." Not to pursue into its details a doctrine which has its place rather in a theological than an anthropological article, it remains to be remarked that the two extracts just given, however significant in themselves, fail to render an account of the view of the human constitution which would probably, among the theological and scholastic leaders of public opinion, count the largest weight of adherence. According to this view, not only life but thought are functions of the animal system, in which man excels all other animals as to height of organisation: but beyond this, man embodies an immaterial and immortal spiritual principle which no lower creature possesses, and which makes the resemblance of the apes to him but a mocking simulance. To pronounce any absolute decision on these conflicting doctrines is foreign to our present purpose, which is to show that all of them count among their adherents men of high rank in science.

Doctrines of creation and evolution.

II. *Origin of Man.*—Available information on this great problem has been multiplied tenfold during the present generation, and the positive dicta of the older authorities are now more and more supplanted by hypotheses based on biological evidence. Opinion as to the genesis of man is divided between the theories of the two great schools of biology, that of creation and that of evolution. In both schools the ancient doctrine of the contemporaneous appearance on earth of all species of animals having been abandoned under the positive evidence of geology, it is admitted that the animal kingdom, past and present, includes a vast series of successive forms, whose appearances and disappearances have taken place at intervals during an immense lapse of ages. The line of inquiry has thus been directed to ascertaining what formative relation subsists among these species and genera, the last link of the argument reaching to the relation between man and the lower creatures preceding him in time. On both the theories here concerned it would be admitted, in the words of Agassiz (*Principles of Zoology*, pp. 205-6), that "there is a manifest progress in the succession of beings on the surface of the earth. This progress consists in an increasing similarity of the living fauna, and, among the vertebrates especially, in their increasing resemblance to man." Agassiz continues, however, in terms characteristic of the creationist school: "But this connection is not the consequence of a direct lineage between the faunas of different ages. There is nothing like parental descent connecting them. The fishes of the Palæozoic age are in no respect the ancestors of the reptiles of the Secondary age, nor does man descend from the mammals which preceded him in the Tertiary age. The link by which they are connected is of a higher and immaterial nature; and their connection is to be sought in the view of the Creator himself, whose aim in forming the earth, in allowing it to undergo the successive changes which geology has pointed out, and in creating successively all the different types of animals which have passed away, was to introduce man upon the surface of our globe. Man is the end towards which all the animal creation has tended from the first appearance of the first Palæozoic fishes." The evolutionist school, on the contrary, maintains that different successive species of animals are in fact connected by parental descent, having become modified in the course of successive generations. Mr Darwin, with whose name and that of Mr Wallace the modern development theory is especially associated, in the preface to his *Descent of Man* (1871), gives precedence among naturalists to Lamarck, as having long ago come to the conclusion "that man is the co-descendant with other species of some ancient, lower, and extinct form." Professor Huxley, remarking (*Man's Place in Nature*, 1863, p. 106) on the crudeness and even absurdity of some of Lamarck's views, dates from Darwin the scientific existence of the development theory. The result of Darwin's application of this theory to man may be given in his own words (*Descent of Man*, part i. ch. 6):—

"The Catarhine and Platyrhine monkeys agree in a multitude of characters, as is shown by their unquestionably belonging to one and the same Order. The many characters which they possess in common can hardly have been independently acquired by so many distinct species; so that these characters must have been inherited. But an ancient form which possessed many characters common to the Catarhine and Platyrhine monkeys, and others in an intermediate condition, and some few perhaps distinct from those now present in either group, would undoubtedly have been ranked, if seen by a naturalist, as an ape or a monkey. And as man under a genealogical point of view belongs to the Catarhine or Old World stock, we must conclude, however much the conclusion may revolt our pride, that our early progenitors would have been properly thus designated. But we must not fall into the error of supposing that the early progenitor of the whole Simian stock, including man, was identical with, or even closely resembled, any existing ape or monkey."

The problem of the origin of man cannot be properly discussed apart from the full problem of the origin of species. The homologies between man and other animals which both schools try to account for; the explanation of the intervals, with apparent want of intermediate forms, which seem to the creationists so absolute a separation between species; the evidence of useless "rudimentary organs," such as in man the external shell of the ear, and the muscle which enables some individuals to twitch their ears, which rudimentary parts the evolutionists claim to be only explicable as relics of an earlier specific condition,—these, which are the main points of the argument on the origin of man, belong to general biology. The philosophical principles which underlie the two theories stand for the most part in strong contrast, the theory of evolution tending toward the supposition of ordinary causes, such as "natural selection," producing modifications in species, whether by gradual accumulation or more sudden leaps, while the theory of creation is prone to have recourse to acts of supernatural intervention (see the Duke of Argyll, *Reign of Law*, ch. v.) A theory has been propounded by Mr Mivart (*Genesis of Species*, 1871) of a natural evolution of man as to his body, combined with a supernatural creation as to his soul; but this attempt to meet the difficulties on both sides seems at present not to have satisfied either. Anthropology waits to see whether the discovery of intermediate forms, which has of late years reduced so many asserted species to mere varieties, will go on till it produces a disbelief in any real separation between neighbouring species, and especially whether geology can furnish traces of the hypothetical animal, man's near ancestor, but not as yet man. In the present state of the argument it may here suffice to have briefly indicated the positions held on either side. (Among other works relating to the development theory as applied to man, see Vogt, *Lectures on Man*; Haeckel, *Natürliche Schöpfungsgeschichte*, 2d ed., 1871.)

Permanent hereditary varieties or races.

III. *Races of Mankind.*—The classification of mankind into a number of permanent varieties or races, rests on grounds which are within limits not only obvious but definite. Whether from a popular or a scientific point of view, it would be admitted that a Negro, a Chinese, and an Australian, belong to three such permanent varieties of men, all plainly distinguishable from one another and from any European. Moreover, such a division takes for granted the idea which is involved in the word race, that each of these varieties is due to special ancestry, each race thus representing an ancient breed or stock, however these breeds or stocks may have had their origin. The anthropological classification of mankind is thus zoological in its nature, like that of the varieties or species of any other animal group, and the characters on which it is based are in great measure physical, though intellectual and traditional peculiarities, such as moral habit and language, furnish important aid. Among the best-marked race-characters are the following:—

Colour of skin, &c.

The colour of the skin has always been held as specially distinctive. The coloured race-portraits of ancient Egypt remain to prove the permanence of complexion during a lapse of a hundred generations, distinguishing coarsely but clearly the types of the red-brown Egyptian, the yellow-brown Canaanite, the comparatively fair Libyan, and the Negro (see Wilkinson, *Ancient Eg.*; Brugsch, *Geogr. Inschr. Altägypt. Denkm.*, vol. ii.) These broad distinctions have the same kind of value as the popular terms describing white, yellow, brown, and black races, which often occur in ancient writings, and are still used. But for scientific purposes greater accuracy is required, and this is now satisfactorily attained by the use of Dr Broca's graduated series of colours as a standard (*Mémoires de la Société d'Anthropologie de Paris*, ii.) By this table the varieties of the human skin may be followed from the fairest hue of the Swede and the darker tint of the Provençal, to the withered-leaf brown of the Hottentot, the chocolate brown of the Mexican, and the brown-black of the West African. The colour of the eyes and hair is also to be defined accurately by Broca's table. This affords, however, less means of distinction, from the extent in which dark tints of hair and iris are common to races whose skins are more perceptibly different; yet some varieties are characteristic, such as the blue eyes and flaxen hair of the fair race of Northern Europe.

Structure and arrangement of hair.

As to the hair, its structure and arrangement is a better indication of race than its tint. The hair differs in quantity between scantiness on the body of the Mongol and profusion on the body of the Aino; while as to the arrangement on the scalp, the tufts of the Bushman contrast with the more equal distribution on the European head. The straight hair of the North American or Malay is recognisable at once as different from the waving or curling hair of the European, and both from the naturally frizzed hair of the Negro. These marked differences are due to the structure of the hair, which, examined in sections under the microscope, varies from the circular section proper to the straight-haired races, to the more or less symmetrically oval or reniform sections belonging to races with curled and twisted hair (see Pruner-Bey in *Mém. de la Soc. Anthrop.*, vol. ii.)

Stature and proportions.

Stature is by no means a general criterion of race, and it would not, for instance, be difficult to choose groups of Englishmen, Kafirs, and North American Indians, whose mean height should hardly differ. Yet in many cases it is a valuable means of distinction, as between the tall Patagonians and the stunted Fuegians, and even as a help in minuter problems, such as separating the Teutonic and Keltic ancestry in the population of England (see Beddoe, "Stature and Bulk of Man in the British Isles," in *Mem. Anthrop. Soc. London*, vol. iii.) Proportions of the limbs, compared in length with the trunk, have been claimed as constituting peculiarities of African and American races; and other anatomical points, such as the conformation of the pelvis, have speciality. But inferences of this class have hardly attained to sufficient certainty and generality to be set down in the form of rules.

Shape of skull.

The conformation of the skull is second only to the colour of the skin as a criterion for the distinction of race. The principal modes of estimating the differences of skulls are the following:—The skull being seen from above, the proportions of the two diameters are estimated on the principle employed by Retzius: taking the longer diameter from front to back as 100, if the shorter or cross diameter falls below 80, the skull may be classed as long (dolichocephalic); while if it exceeds 80, the skull may be classed as broad (brachycephalic); or a third division may be introduced between these as intermediate (mesocephalic), comprehending skulls with a proportionate breadth of 75 to 80, or thereabout. The percentage of breadth to length measured in this manner is known as the cephalic index; thus, the cephalic index of a Negro or Australian may be as low as 72, and that of a Tatar as high as 88, while the majority of Europeans have an index not departing in either direction very far from 78. The cephalic height is measured in the same way as a percentage of the length. The back view (norma occipitalis) of the skull is distinguished as rounded, pentagonic, &c., and the base view of the skull shows the position of the occipital foramen and the zygomatic arches. The position of the jaws is recognised as important, races being described as prognathous when the jaws project far, as in the Australian or Negro, in contradistinction to the orthognathous type, which is that of the ordinary well-shaped European skull. On this distinction in great measure depends the celebrated "facial angle," measured by Camper as a test of low and high races; but this angle is objectionable as resulting partly from the development of the forehead and partly from the position of the jaws. The capacity of the cranium is estimated in cubic measure by filling it with sand, &c., with the general result that the civilised white man is found to have a larger brain than the barbarian or savage.

Classification of races on cranial measurements has long been attempted by eminent anatomists, such as Blumenbach and Retzius, while the later labours of Von Baer, Welcker, Davis, Broca, Busk, Lucae, and many others, have brought the distinctions to extreme minuteness. In certain cases great reliance may be placed on such measurements. Thus the skulls of an Australian and a Negro would be generally distinguished by their narrowness and the projection of the jaw from that of any Englishman; while, although both the Australian and Negro are thus dolichocephalic and prognathous, the first would usually differ perceptibly from the second in its upright sides and strong orbital ridges. The relation of height to breadth may furnish a valuable test; thus both the Kafir and the Bushman are dolichocephalic, with an index of about 72, but they differ in the index of height, which may be 73 and 71 respectively, in the one case more than the width and in the other less. It is, however, acknowledged by all experienced craniologists, that the shape of the skull may vary so much within the same tribe, and even the same family, that it must be used with extreme caution, and if possible only in conjunction with other criteria of race.

Features.

The general contour of the face, in part dependent on the form of the skull, varies much in different races, among whom it is loosely defined as oval, lozenge-shaped, pentagonal, &c. Of particular features, some of the most marked contrasts to European types are seen in the oblique Chinese eyes, the broad-set Kamchadal cheeks, the pointed Arab chin, the snub Kirghis nose, the fleshy protuberant Negro lips, and the broad Kalmuk ear. Taken altogether, the features have a typical character which popular observation seizes with some degree of correctness, as in the recognition of the Jewish countenance in a European city.

Constitution and character.

The state of adaptation in which each people stands to its native climate forms a definite race-character. In its extreme form this is instanced in the harmful effect of the climate of India on children of European parents, and the corresponding danger in transporting natives of tropical climates to England. Typical instances of the relation of race-constitutions to particular diseases are seen in the liability of Europeans in the West Indies to yellow fever, from which Negroes are exempt, and in the habitation by tribes in India of so-called "unhealthy districts," whose climate is deadly to Europeans, and even to natives of neighbouring regions. Even the vermin infesting different races of men are classified by Mr A. Murray (*Trans. R. Soc. Edin.*, vol. xxii.) as distinct.

The physical capabilities of different races are known to differ widely, but it is not easy to discriminate here between hereditary race-differences and those due to particular food and habit of life. A similar difficulty has hitherto stood in the way of any definite classification of the emotional, moral, and intellectual characters of races. Some of the most confident judgments which have been delivered on this subject have been dictated by prejudice or wilful slander, as in the many lamentable cases in which slave-holders and conquerors have excused their ill-treatment of subject and invaded races on the ground of their being creatures of bestial nature in mind and morals. Two of the best-marked contrasts of mental type recorded among races are Mr A. R. Wallace's distinction between the shy, reserved, and impassive Malay and the sociable and demonstrative Papuan (*Tr. Eth. Soc.*, vol iii. p. 200), and the very similar difference pointed out by Spix and Martius between the dull and morose natives of the Brazilian forests, and the lively sensuous African Negroes brought into contact with them (*Reise in Brasilien*, vol. i.) In general, however, descriptions of national or racial character are so vitiated by the confusion of peculiarity of natural character with stage of civilisation, that they can only be made use of with the greatest reserve.

The relation of language to race is discussed below. (Section V.)

General classification of races.

Were the race-characters indicated in the foregoing paragraphs constant in degree or even in kind, the classification of races would be an easy task. In fact it is not so, for every division of mankind presents in every character wide deviations from a standard. Thus the Negro race, well marked as it may seem at the first glance, proves on closer examination to include several shades of complexion and features, in some districts varying far from the accepted Negro type; while the examination of a series of native American tribes shows that, notwithstanding their asserted uniformity of type, they differ in stature, colour, features, and proportions of skull. (See Prichard, *Nat. Hist. of Man;* Waitz, *Anthropology*, part i. sec. 5.) Detailed anthropological research, indeed, more and more justifies Blumenbach's words, that "innumerable varieties of mankind run into one another by insensible degrees." This state of things, due partly to mixture and crossing of races, and partly to independent variation of types, makes the attempt to arrange the whole human species within exactly bounded divisions an apparently hopeless task. It does not follow, however, that the attempt to distinguish special races should be given up, for there at least exist several definable types, each of which so far prevails in a certain population as to be taken as its standard.

Quetelet's method.

M. Quetelet's plan of defining such types will probably meet with general acceptance as the scientific method proper to this branch of anthropology. It consists in the determination of the standard, or typical "mean man" (*homme moyen*) of a population, with reference to any particular quality, such as stature, weight, complexion, &c. In the case of stature, this would be done by measuring a sufficient number of men, and counting how many of them belong to each height on the scale. If it be thus ascertained, as it might be in an English district, that the 5 ft. 7 in. men form the most numerous group, while the 5 ft. 6 in. and 5 ft. 8 in. men are less in number, and the 5 ft. 5 in. and 5 ft. 9 in. still fewer, and so on until the extremely small number of extremely short or tall individuals of 5 ft. or 7 ft. is reached, it will thus be ascertained that the stature of the mean or typical man is to be taken as 5 ft. 7 in. The method is thus that of selecting as the standard the most numerous group, on both sides of which the groups decrease in number as they vary in type. Such classification may show the existence of two or more types in a community, as, for instance, the population of a Californian settlement made up of Whites and Chinese might show two predominant groups (one of 5 ft. 8 in., the other of 5 ft. 4 in.) corresponding to these two racial types. It need hardly be said that this method of determining the mean type of a race, as being that of its really existing and most numerous class, is altogether superior to the mere calculation of an average, which may actually be represented by comparatively few individuals, and those the exceptional ones. For instance, the average stature of the mixed European and Chinese population just referred to might be 5 ft. 6 in.—a worthless and, indeed, misleading result. (For particulars of Quetelet's method, see his *Physique Sociale*, 1869, and *Anthropométrie*, 1870.) The measurement and description of the various races of men are now carried to great minuteness (the tables in Scherzer and Schwarz, *Reise der Novara*, and those of Fritsch, *Die Eingeborenen Sud-Afrika's*, 1872, may be cited as examples of modern method), so that race-classification is rapidly improving as to both scope and accuracy. Even where comparatively loose observations have been made, it is possible, by inspection of considerable numbers of individuals, to define the prevalent type of a race with tolerable approximation to the real mean or standard man. It is in this way that the subdivision of mankind into races, so far as it has been done to any purpose, has been carried out by anthropologists.

These classifications have been numerous, and though, regarded as systems, most of them are now seen at the first glance to be unsatisfactory, yet they have been of great value in systematising knowledge, and are all more or less based on indisputable distinctions. Blumenbach's division, though published nearly a century ago (1781), has had the greatest influence. He reckons five races, viz., Caucasian, Mongolian, Ethiopian, American, Malay (see the collected edition of his *Treatises*, p. 264, published by the Anthropological Society). The ill-chosen name of Caucasian, used by Blumenbach to denote what may be called white men, is still current; it brings into one race peoples such as the Arabs and Swedes, although these are scarcely less different than the Americans and Malays, who are set down as two distinct races. Again, two of the best-marked varieties of mankind are the Australians and the Bushmen, neither of whom, however, seem to have a natural place in Blumenbach's series. The yet simpler classification by Cuvier into Caucasian, Mongol, and Negro, corresponds in some measure with a division by mere complexion into white, yellow, and black races; but neither this threefold division, nor the ancient classification into Semitic, Hamitic, and Japhetic nations can be regarded as separating the human types either justly or sufficiently (see Prichard, *Natural History of Man*, sec. 15; Waitz, *Anthropology*, vol. i. part i. sec. 5). Schemes which set up a larger number of distinct races, such as the eleven of Pickering, the fifteen of Bory de St Vincent, and the sixteen of Desmoulins, have the advantage of finding niches for most well-defined human varieties; but no modern naturalist would be likely to adopt any one of these as it stands. In criticism of Pickering's system, it is sufficient to point out that he divides the white nations into two races, entitled the Arab and the Abyssinian (Pickering, *Races of Man*, chap. i.) Agassiz, Nott, Crawfurd, and others who have assumed a much larger number of races or species of man, are not considered to have satisfactorily defined a corresponding number of distinguishable types. On the whole, Professor Huxley's recent scheme (*Journal of the Ethnological Society*, vol. ii. p. 404, 1870) probably approaches more nearly than any other to such a tentative classification as may be accepted in definition of the principal varieties of mankind, regarded from a zoological point of view, though anthropologists may be disposed to erect into separate races several of his widely-differing sub-races. He distinguishes four principal types of mankind, the Australioid, Negroid, Mongoloid, and Xanthochroic, adding a fifth variety, the Melanochroic.

Schemes of Blumenbach, Cuvier, &c.

Huxley's classification.

The special points of the Australioid are a chocolate-brown skin, dark brown or black eyes, black hair (usually wavy), narrow (dolichocephalic) skull, brow-ridges strongly developed, projecting jaw, coarse lips, and broad nose. This type is best represented by the natives of Australia, and next to them, by the indigenous tribes of Southern India, the so-called coolies. The Egyptians to some degree approach this type; they are, however, held by good authorities to be a modified African race.

The Negroid type is primarily represented by the Negro of Africa, between the Sahara and the Cape district, including Madagascar. The skin varies from dark brown to brown-black, with eyes of similar dark hue, and hair usually black, and always crisp or woolly. The skull is narrow (dolichocephalic), with orbital ridges not prominent, prognathous, with depressed nasal bones, causing the nose to be flat as well as broad; and the lips are coarse and projecting. Two important families are classed in this system as special modifications of the Negroid type. First, the Bushman of South Africa is diminutive in stature, and of yellowish-brown complexion; the Hottentot is supposed to be the result of crossing between the Bushman and ordinary Negroid. Second, the Negritos of the Andaman Islands, the peninsula of Malacca, the Philippines and other islands, to New Caledonia and Tasmania, are mostly dolichocephalic, with dark skins and woolly hair. In various districts they tend towards other types, and show traces of mixture.

The Mongoloid type prevails over the vast area lying east of a line drawn from Lapland to Siam. Its definition includes a short, squat build, a yellowish brown complexion, with black eyes and black straight hair, a broad (brachycephalic) skull, usually without prominent brow-ridges, flat small nose, and oblique eyes. The dolichocephalic Chinese and Japanese in other respects correspond. Various other important branches of the human species are brought into connection with the Mongoloid type, though on this view the differences they present raise difficult problems of gradual variation, as well as of mixture of race; these are the Dyak-Malays, the Polynesians, and the Americans.

The Xanthochroi, or fair whites — tall, with almost colourless skin, blue or grey eyes, hair from straw colour to chestnut, and skulls varying as to proportionate width—are the prevalent inhabitants of Northern Europe, and the type may be traced into North Africa, and eastward as far as Hindostan. On the south and west it mixes with that of the Melanochroi, or dark whites, and on the north and east with that of the Mongoloids.

The Melanochroi, or dark whites, differ from the fair whites in the darkening of the complexion to brownish and olive, and of the eyes and hair to black, while the stature is somewhat lower and the frame lighter. To this class belong a large part of those classed as Kelts, and of the populations of Southern Europe, such as Spaniards, Greeks, and Arabs, extending as far as India; while endless intermediate grades between the two white types testify to ages of intermingling. Professor Huxley is disposed to account for the Melanochroi as themselves the result of crossing between the Xanthochroi and the Australioids. Whatever ground there may be for his view, it is obviously desirable to place them in a class by themselves, distinguishing them by an appropriate name.

In determining whether the races of mankind are to be classed as varieties of one species, it is important to decide whether every two races can unite to produce fertile offspring. It is settled by experience that the most numerous and well-known crossed races, such as the Mulattos, descended from Europeans and Negroes—the Mestizos, from Europeans and American indigenes—the Zambos, from these American indigenes and Negroes, &c., are permanently fertile. They practically constitute sub-races, with a general blending of the characters of the two parents, and only differing from fully established races in more or less tendency to revert to one or other of the original types. It has been argued, on the other hand, that not all such mixed breeds are permanent, and especially that the cross between Europeans and Australian indigenes is almost sterile; but this assertion, when examined with the care demanded by its bearing on the general question of hybridity, has distinctly broken down. On the whole, the general evidence favours the opinion that any two races may combine to produce a new sub-race, which again may combine with any other variety. (See Waitz, *Anthropology*, vol. i. part i. sec. 3; Darwin, *Descent of Man*, part i. ch. 7; Prichard, *Nat. Hist. of Man*, sect. 5; on the other hand, Broca, *Phenomena of Hybridity in the Genus Homo*, 1864.) Thus, if the existence of a small number of distinct races of mankind be taken as a starting-point, it is obvious that their crossing would produce an indefinite number of secondary varieties, such as the population of the world actually presents. The working out in detail of the problem, how far the differences among complex nations, such as those of Europe, may have been brought about by hybridity, is still, however, a task of almost hopeless intricacy. Among the boldest attempts to account for distinctly-marked populations as resulting from the intermixture of two races, are Professor Huxley's view that the Hottentots are hybrid between the Bushmen and the Negroes, and his more important suggestion, that the Melanochroic peoples of Southern Europe are of mixed Xanthochroic and Australioid stock.

Origin of races.

The problem of ascertaining how the small number of races, distinct enough to be called primary, can have assumed their different types, has been for years the most disputed field of anthropology, the battle-ground of the rival schools of monogenists and polygenists. The one has claimed all mankind to be descended from one original stock, and generally from a single pair; the other has contended for the several primary races being separate species of independent origin. It is not merely as a question of natural history that the matter has been argued. Biblical authority has been appealed to, mostly on the side of the monogenists, as recording the descent of mankind from a single pair. (See, for example, Horne's *Introduction to the Scriptures;* the Speaker's Commentary, Gen. i.) On the other hand, however, the polygenists not less confidently claim passages from which they infer the existence of non-Adamite, as well as Adamite races of man. (See, for example, R. S. Poole, *Genesis of the Earth and Man.*) Nor have political considerations been without influence, as where, for instance, one American school of ethnologists have been thought to have formed, under the bias of a social system recognising slavery, their opinion that the Negro and the white man are of different species. (See Morton, *Crania Americana;* Nott and Gliddon, *Types of Mankind.*) Of the older school of scientific monogenists, Blumenbach and Prichard are eminent representatives, as is Quatrefages of the more modern. The great problem of the monogenist theory is to explain by what course of variation the so different races of man have arisen from a single stock. In ancient times little difficulty was felt in this, authorities such as Aristotle and Vitruvius seeing in climate and circumstance the natural cause of racial differences, the Ethiopian having been blackened by the tropical sun, &c. Later and closer observations, however, have shown such influences to be, at any rate, far slighter in amount and slower in operation than was once supposed. M. de Quatrefages brings forward (*Unité de l'Espèce Humaine*, Paris, 1861, ch. 13) his strongest arguments for the variability of races under change of climate, &c. (*action du milieu*), instancing the asserted alteration in complexion, constitution, and character of Negroes in America, and Englishmen in America and Australia. But although the reality of some such modification is not disputed, especially as to stature and constitution, its amount is not enough to upset the counter-proposition of the remarkable permanence of type displayed by races ages after they have been transported to climates extremely different from that of their former home. Moreover, physically different races, such as the Bushmen and Negroids in Africa, show no signs of approximation under the influence of the same climate; while, on the other hand, the coast tribes of Tierra del Fuego and forest tribes of tropical Brazil continue to resemble one another, in spite of extreme differences of climate and food. Mr Darwin, than whom no naturalist could be more competent to appraise the variation of a species, is moderate in his estimation of the changes produced on races of man by climate and mode of life within the range of history (*Descent of Man*, part i. ch. 4 and 7). The slightness and slowness of variation in human races having become known, a great difficulty of the monogenist theory was seen to lie in the shortness of the chronology with which it was formerly associated. Inasmuch as several well-marked races of mankind, such as the Egyptian, Phœnician, Ethiopian, &c., were much the same three or four thousand years ago as now, their variation from a single stock in the course of any like period could hardly be accounted for without a miracle. This difficulty was escaped by the polygenist theory, which, till a few years since, was gaining ground. (See Pouchet, *Plurality of the Human Race*, 2nd ed., 1864, Introd.) Two modern views have, however, intervened which have tended to restore, though under a new aspect, the doctrine of a single human stock. One has been the recognition of man having existed during a vast period of time (see sec. IV., *Antiquity of Man*), which made it more easy to assume the continuance of very slow natural variation as having differenced even the white man and the Negro among the descendants of a common progenitor. The other view is that of the evolution or development of species, at the present day so strongly upheld among naturalists. It does not follow necessarily from a theory of evolution of species that mankind must have descended from a single stock, for the hypothesis of development admits of the argument, that several simious species may have culminated in several races of man (Vogt, *Lectures on Man*, London, 1864, p. 463). The general tendency of the development theory, however, is against constituting separate species where the differences are moderate enough to be accounted for as due to variation from a single type. Mr Darwin's summing up of the evidence as to unity of type throughout the races of mankind is as distinctly a monogenist argument as those of Blumenbach, Prichard, or Quatrefages—

Variations of human type.

"Although the existing races of man differ in many respects, as in colour, hair, shape of skull, proportions of the body, &c., yet, if their whole organisation be taken into consideration, they are found to resemble each other closely in a multitude of points. Many of these points are of so unimportant, or of so singular a nature, that it is extremely improbable that they should have been independently acquired by aboriginally distinct species or races. The same remark holds good with equal or greater force with respect to the numerous points of mental similarity between the most distinct races of man. . . . . . Now, when naturalists observe a close agreement in numerous small details of habits, tastes, and dispositions between two or more domestic races, or between nearly allied natural forms, they use this fact as an argument that all are descended from a common progenitor, who was thus endowed; and, consequently, that all should be classed under the same species. The same argument may be applied with much force to the races of man."—(Darwin, *Descent of Man*, part i. ch. 7.)

Time of fixture of race-types

A suggestion by Mr A. R. Wallace has great importance in the application of the development theory to the origin of the various races of man; it is aimed to meet the main difficulty of the monogenist school, how races which have remained comparatively fixed in type during the long period of history, such as the white man and the Negro, should have, in even a far longer period, passed by variation from a common original. Mr Wallace's view is substantially that the remotely ancient representatives of the human species, being as yet animals too low in mind to have developed those arts of maintenance and social ordinances by which man holds his own against influences from climate and circumstance, were in their then wild state much more plastic than now to external nature; so that "natural selection" and other causes met with but feeble resistance in forming the permanent varieties or races of man, whose complexion and structure still remain fixed in their descendants. (See Wallace, *Contributions to the Theory of Natural Selection*, p. 319.) On the whole, it may be asserted that the doctrine of the unity of mankind now stands on a firmer basis than in previous ages. It would be premature to judge how far the problem of the origin of races may be capable of exact solution; but the experience of the last few years countenances Mr Darwin's prophecy, that before long the dispute between the monogenists and the polygenists will die a silent and unobserved death.

Chronology deficient.

IV. *Antiquity of Man.*—It was until of late years commonly held among the educated classes, that man's first appearance on earth might be treated on a historical basis as matter of record. It is true that the schemes drawn up by chronologists differed widely, as was naturally the case, considering the variety and inconsistency of their documentary data. On the whole, the scheme of Archbishop Usher, who computed that the earth and man were created in 4004 B.C., was the most popular. (See early editions of the *Encyclopædia Britannica*, art. "Creation.") It is no longer necessary, however, to discuss these chronologies, inasmuch as new evidence has so changed the aspect of the subject, that the quasi-historical schemes of the last century would now hardly be maintained by any competent authority of any school. Geology, notwithstanding the imperfection of its results, has made it manifest that our earth must have been the seat of vegetable and animal life for an immense period of time; while the first appearance of man, though comparatively recent, is positively so remote, that an estimate between twenty and a hundred thousand years may fairly be taken as a minimum. This geological claim for a vast antiquity of the human race is supported by the similar claims of prehistoric archæology and the science of culture, the evidence of all three departments of inquiry being intimately connected, and in perfect harmony.

Evidence of Prehistoric Archæology.

During the last half century, the fact has been established that human bones and objects of human manufacture occur in such geological relation to the remains of fossil species of elephant, rhinoceros, hyæna, bear, &c., as to lead to the distinct inference that man already existed during the ancient period of these now extinct mammalia. The not quite conclusive researches of MM. Tournal and Christol in limestone caverns of the south of France date back to 1828. About the same time Dr Schmerling of Liége was exploring the ossiferous caverns of the valley of the Meuse, and satisfied himself that the men whose bones he found beneath the stalagmite floors, together with bones cut and flints shaped by human workmanship, had inhabited this Belgian district at the same time with the cave-bear and several other extinct animals whose bones were imbedded with them (*Recherches sur les Ossements fossiles découverts dans les Cavernes de la Province de Liége*, Liége, 1833–4). This evidence, however, met with little acceptance among scientific men. Nor, at first, was more credit given to the discovery by M. Boucher de Perthes, about 1841, of rude flint hatchets in a sand-bed containing remains of mammoth and rhinoceros at Menchecourt near Abbeville, which first find was followed by others in the same district (see Boucher de Perthes, *De l'Industrie Primitive, ou les Arts à leur Origine*, 1846; *Antiquités Celtiques et Antédiluviennes*, Paris, 1847, &c.); between 1850 and 1860 competent French and English geologists, among them Rigollot, Falconer, Prestwich, and Evans, were induced to examine into the facts, and found the evidence irresistible that man existed and used rude implements of chipped flint during the Quaternary or Drift period. Further investigations were now made, and overlooked results of older ones reviewed. In describing Kent's Hole, near Torquay, Mr Godwin-Austen had maintained, as early as 1840 (*Proc. Geo. Soc. London*, vol. iii. p. 286), that the human bones and worked flints had been deposited indiscriminately together with the remains of fossil elephant, rhinoceros, &c.; a minute exploration of this cavern has since been carried on under the superintendence of Messrs Vivian, Pengelly, and others, fully justifying Mr Godwin-Austen's early remark, that "there is no *a priori* reason why man and the several animals whose remains occur in caves and in gravel should not have lived here at some remote time" (see Pengelly, "Literature of Kent's Cavern," in *Trans. Devonshire Association*, 1868). Especially certain caves and rock-shelters in the province of Dordogne, in central France were examined by a French and an English archæologist, Mons. Edouard Lartet and Mr Henry Christy, the remains discovered showing the former prevalence of the rein-deer in this region, at that time inhabited by savages, whose bone and stone implements indicate a habit of life similar to that of the Esquimaux. Moreover, the coexistence of man with a fauna now extinct or confined to other districts was brought to yet clearer demonstration, by the discovery in these caves of certain drawings and carvings of the animals done by the ancient inhabitants themselves, such as a group of rein-deer on a piece of rein-deer horn, and a sketch of a mammoth, showing this elephant's long hair, on a piece of a mammoth's tusk from La Madeleine (Lartet and Christy, *Reliquiæ Aquitanicæ*, ed. by T. R. Jones, London, 1865, &c.) These are among the earliest and principal of a series of discoveries of human relics belonging to what may be termed geological antiquity, with which should be mentioned Mr Boyd Dawkins's examination of the hyæna den of Wokey Hole, Dr Lund's researches in the caves of Brazil, those in the south of France by the Marquis de Vibraye and MM. Garrigou and Filhol, those in Sicily by Dr Falconer, and Mr Bruce Foote's discovery of rude quartzite implements in the laterite of India. Fuller details of the general subject will be found in Sir C. Lyell's *Antiquity of Man*, 4th ed., London, 1873; Sir John Lubbock's *Prehistoric Times*, 3d ed., London, 1873; Dr H. Falconer's *Palæontological Memoirs*, London, 1868; the volumes of *Proceedings of the International Congress of Prehistoric Archæology*; and the periodical *Matériaux pour l'Histoire Primitive et Naturelle de l'Homme*, edited at first by De Mortillet, and since by Trutat and Cartailhac.

Cave period.

Drift period.

Antiquity of Quaternary Man

This evidence is now generally accepted by geologists as carrying back the existence of man into the period of the post-glacial drift, in what is now called the Quaternary period. That this indicates an antiquity at least of tens of thousands of years may be judged in several ways. The very position in which these rude instruments were found showed that they belonged to a time quite separate from that of history. Thus, at St Acheul flint hatchets occur in a gravel-bed immediately overlying the chalk, which bed is covered by some 12 feet of sand and marl, capped by a layer of soil, which is shown by graves of the Gallo-Roman period to have been hardly altered during the last 1500 years. This distinction between the drift deposits and those containing relics of historic ages is, as a general rule, evident at a glance. Next, the succession of ages to which different classes of remains belong is well marked; the drift implements belong to the palæolithic or old stone age, when as yet the implements were extremely rude, and not ground or polished; above these in deposit, and therefore later in time, come the artistically shaped and polished celts of the neolithic or new stone age; above these, again, relics of the bronze and early iron ages, with which historical antiquity in Europe begins. Again, the animals of the Quaternary period, whose bones are found with the rude stone implements, comprise several species of mammalia which have since become extinct, such as the mammoth, the hairy rhinoceros, and the Irish elk, while others, such as the rein-deer and musk-ox, now only inhabit remote districts. It is generally considered that such a fauna indicates, at any rate during part of the Quaternary period, a severer climate than now prevails in France and England. This difference from the present conditions seems to confirm the view, that the twenty centuries of French and English history form but a fraction of the time which has elapsed since the stone implements of prehistoric tribes were first buried under beds of gravel and sand by the rivers now represented by the Thames or the Somme. Still vaster, however, is the idea of antiquity suggested by the geographical conformation of such valleys as these in which these rivers flow. The drift-beds lie on their sides often 100 to 200 feet, and even more, above the present flood-levels. As such highest deposits seem to mark the time when the rivers flowed at heights so far above the present channels, it follows that the drift-beds, and the men whose works they enclose, must have existed during a great part of the time occupied by the rivers in excavating their valleys down to their present beds. Granting it as possible that the rivers by which this enormous operation was performed were of greater volume and proportionately still greater power in flood-time than the present streams, which seem so utterly inadequate to their valleys, and granting also, that under different conditions of climate the causing of debâcles by ground-ice may have been a powerful excavating agent, nevertheless, with all such allowances the reckoning of ages seems vastly out of proportion to historical chronology. It is not convenient to discuss here Mr Prestwich's division of the drift gravels into high and low level beds, nor Mr A. Tylor's argument against this division, nor the latter's theory of a Pluvial period succeeding the Glacial period (see *Quart. Journ. Geol. Soc.*, vol. xxiv. part 2, vol. xxv. part 1). The geology of the Quaternary or Post-tertiary gravels, on which the geological argument for the high antiquity of man mainly rests, has been especially treated by Prestwich in the *Philos. Trans.*, 1860, p. 277, and 1864, p. 247; see also J. Evans, *Ancient Stone Impts.*, ch. 25; references to the writings of other geologists will be found in the already mentioned works of Lyell and Lubbock.

Depth of deposits of human age.

Beside these arguments, which suggest high antiquity rather than offer means of calculation, certain inferences (accounts of which are also given in the last-named works) have been tentatively made from the depth of mud, earth, peat, &c. which has accumulated above relics of human art imbedded in ancient times. Among these is Mr Horner's argument from the numerous borings made in the alluvium of the Nile valley to a depth of 60 feet, where down to the lowest level fragments of burnt brick and pottery were always found, showing that people advanced enough in the arts to bake brick and pottery have inhabited the valley during the long period required for the Nile inundations to deposit 60 feet of mud, at a rate probably not averaging more than a few inches in a century. Another argument is that of Professor von Morlot, based on a railway section through a conical accumulation of gravel and alluvium, which the torrent of the Tinière has gradually built up where it enters the Lake of Geneva near Villeneuve. Here three layers of vegetable soil appear, proved by the objects imbedded in them to have been the successive surface-soils in two prehistoric periods and in the Roman period, and which now lie 4, 10, and 19 feet underground; on this it is computed that if 4 feet of soil were formed in the 1500 years since the Roman period, we must go 5000 years farther back for the date of the earliest human inhabitants. Calculations of this kind, loose as they are, deserve attention

Lake habitations.

The interval between the Quaternary or Drift period and the period of historical antiquity is to some extent bridged over by relics of various intermediate civilisations, mostly of the lower grades, and in some cases reaching back to remote dates. The lake dwellings of Switzerland are perhaps among the more recent of these. They were villages of huts built on piles in the water at some distance from the shore, for security from attack—in fact, fortified water settlements of the same nature as those of Lake Prasias in the time of Herodotus, and as those still inhabited in New Guinea and West Africa. The remains of these Swiss villages are found with the stumps of the piles still standing, often imbedded in an accumulation of mud or growth of peat which has preserved a kind of illustrative museum of the arts and habits of the lake men. From examination of the sites, it appears that the settlements are of various dates, from the neolithic or polished stone period, when instruments of metal were still unknown, to the time when bronze was introduced, and beyond this into the later age marked by the use of iron. A few of the lake villages lasted on till the Roman dominion, as is proved by the presence of Roman coins and pottery, but they were soon afterwards abandoned, so that their very existence was forgotten, and their rediscovery only dates from 1853, when the workmen excavating a bed of mud on the shore of the Lake of Zurich found themselves standing among the piles of a lake settlement. In Germany, Italy, and other countries, similar remains of a long pre-Roman civilisation have been found. (The special works on lake habitations are Dr Keller's *Lake Dwellings*, translated by J. E. Lee, London, 1866; and Troyon's *Habitations Lacustres*). Indications of man's antiquity, extending farther back into prehistoric times, are furnished by the Danish shell-heaps or "kjökkenmödding," which term, meaning "kitchen refuse-heap," has been Anglicised in "kitchen midden" (the word "midden," a dung-heap, being still current in the north of England). Along the shores of nearly all the Danish islands extensive beds or low mounds, like raised beaches, may be seen, consisting chiefly of innumerable cast-away shells, intermingled with bones, &c. Such shell-heaps are found in all quarters of the globe by the sea-shore, and may be sometimes seen in process of formation; they are simply the accumulations of shells and refuse thrown away near the huts of rude tribes subsisting principally on shell-fish. The Danish kitchen middens, however, are proved to belong to a very ancient time, by the remains of the quadrupeds, birds, and fish, which served as the food of these rude hunters and fishers; among these are bones of the wild bull, beaver, seal, and great auk, all now extinct or rare in this region. Moreover, a striking proof of the antiquity of these shell-heaps is, that the shells of the common oyster are found of full size, whereas it cannot live at present in the brackish waters of the Baltic except near its entrance, so that it is inferred that the shores where the oyster at that time flourished were open to the salt sea. Thus, also, the eatable cockle, mussel, and periwinkle abounding in the kitchen middens are of full ocean size, whereas those now living in the adjoining waters are dwarfed to a third of their natural size by the want of saltness. It thus appears that the connection between the ocean and the Baltic has notably changed since the time of these rude stone-age people. (See the reports by Forchhammer, Steenstrup, and Worsaae on the kjökkenöddings, made to the Copenhagen Academy of Sciences.) Various other evidence is adduced in this part of the argument, such as that from the Danish peat-mosses, which show the existence of man at a time when the Scotch fir was abundant; at a later period the firs were succeeded by oaks, which have again been almost superseded by beeches, a succession of changes which indicate a considerable lapse of time. For further references to special accounts, the reader may consult the already mentioned general works on the antiquity of prehistoric man.

Shell-heaps

Historical antiquity.

Lastly, chronicles and documentary records, taken in connection with archæological relics of the historical period, carry back into distant ages the starting-point of actual history, behind which lies the evidently vast period only known by inferences from the relations of languages and the stages of development of civilisation. Thus, Egypt affords some basis for estimating a minimum date for its ancient population. The hieroglyphic inscriptions, the most ancient written records of the world, preserve direct memorials of a time which can hardly be less, and may be much more, than 3000 years before the Christian era. With all the doubt which besets the attempt to extract a definite chronology from the Egyptian names of kings and lists of dynastics (see EGYPT), their salient points fit with the historical records of other nations. Thus, the great Ramesside dynasty, known among Egyptologists as the 19th dynasty, corresponds with the mention of the building of the city of Raamses in Exod. i. 11; Amenophis III., called by the Greeks Memnon, belongs to the previous 18th dynasty; while the three pyramid kings, whom Herodotus mentions as Cheops, Chephren, and Mykerinos, and whose actual Egyptian names are read in the hieroglyphic lists as Chufu, Chafra, and Menkaura, are set down in the 4th dynasty. Lepsius may not be over-estimating when he dates this dynasty back as far as 3124 B.C., and carries the more dubious previous dynasties back to 3892 B.C. before reaching what are known as the mythical dynastics, which probably have their bases rather in astronomical calculations than in history (Lepsius, *Königsbuch der alten Ægypter*, Berlin, 1858; compare the computations of Brugsch, Bunsen, Hincks, Wilkinson, &c.)

The Greeks of the classic period could discuss the Egyptian chronologies with priests and scribes who perpetuated the languages and records of their earliest dynasties; and as the Septuagint translation of the Bible was made at Alexandria, it is not impossible that its giving to man a considerably greater antiquity than that of the Hebrew text may have been due to the influence of the Egyptian chronology. Even if the lowest admissible calculations be taken, this will not invalidate the main fact, that above 4000 years ago the Egyptian nation already stood at a high level of industrial and social culture. The records of several other nations show that as early or not much later than this they had attained to a national civilisation. The Bible, whose earliest books are among the earliest existing chronicles, shows an Israelite nation existing in a state of patriarchal civilisation previous to the already mentioned time of contact with Egypt. In ancient Chaldæa, the inscribed bricks of Urukh's temples probably belong to a date beyond 2000 years B.C. (G. Rawlinson, *Five Great Monarchies of the Ancient Eastern World*, London, 1862, &c., vol. i. ch. 8).

The Chinese dynasties, like those of Egypt, begin with an obviously mythical portion, and continue into actual history, the difficulty is to draw the line where genuine record begins. Those who reckon authentic history only from the dynasty of Chow, beginning about 1100 B.C., during which Confucius lived, will at any rate hardly deny the existence of the earlier dynasty of Shang, previous to which the yet earlier dynasty of Hea is recorded; so that, though much that is related of these periods may be fabulous, it seems certain that there was a Chinese nation and a Chinese civilisation reaching back beyond 2000 B.C. (see Sir John Davis, *The Chinese*; Pauthier, *Livres Sacrés de l'Orient*; Shu-King, &c.)

Time of development of culture and language.

Till of late it was a commonly received opinion that the early state of society was one of comparatively high culture, and those who held this opinion felt no difficulty in assigning the origin of man to a time but little beyond the range of historical records and monuments. At present, however, the view has become paramount that the civilisation of the world has been gradually developed from an original stone-age culture, such as characterises modern savage life. To hold this opinion necessitates the adding to the 4000 or 5000 years to which the ancient civilisations of Egypt, Babylon, and China date back, a probably much greater length of time, during which the knowledge, arts, and institutions of these countries attained to their remarkably high level. The evidence of comparative philology corroborates this judgment. Thus, Hebrew and Arabic are closely related languages, neither of them the original of the other, but both sprung from some parent language more ancient than either. When, therefore, the Hebrew records have carried back to the most ancient admissible date the existence of the Hebrew language, this date must have been long preceded by that of the extinct parent language of the whole Semitic family; while this again was no doubt the descendant of languages slowly shaping themselves through ages into this peculiar type. Yet more striking is the evidence of the Aryan or Indo-European family of languages. The Hindus, Medes, Persians, Greeks, Romans, Germans, Kelts, and Slaves make their appearance at more or less remote dates as nations separate in language as in history. Nevertheless, it is now acknowledged that at some far remoter time, before these nations were divided from the parent stock, and distributed over Asia and Europe by the Aryan dispersion, a single barbaric people stood as physical and political representative of the nascent Aryan race, speaking a now extinct Aryan language, from which, by a series of modifications not to be estimated as possible within many thousands of years, there arose languages which have been mutually unintelligible since the dawn of history, and between which it was only possible for an age of advanced philology to trace the fundamental relationship.

From the combination of these considerations, it will be seen that the farthest date to which documentary record extends, is now generally regarded by anthropologists as but the earliest distinctly visible point of the historic period, beyond which stretches back a vast indefinite series of prehistoric ages.

Evidence of philology

V. *Language*.—In examining how the science of language bears on the general problems of anthropology, it is not necessary to discuss at length the critical questions which arise, the principal of which are considered elsewhere. (See LANGUAGE.) Philology is especially appealed to by anthropologists as contributing to the following lines of argument. A primary mental similarity of all branches of the human race is evidenced by their common faculty of speech, while at the same time secondary diversities of race-character and history are marked by difference of grammatical structure and of vocabularies. The existence of groups or families of allied languages, each group being evidently descended from a single language, affords one of the principal aids in classifying nations and races. The adoption by one language of words originally belonging to another, proving as it does the fact of intercourse between two races, and even to some extent indicating the results of such intercourse, affords a valuable clue through obscure regions of the history of civilisation.

Faculty of language.

Communication by gesture-signs, between persons unable to converse in vocal language, is an effective system of expression common to all mankind. Thus, the signs used to ask a deaf and dumb child about his meals and lessons, or to communicate with a savage met in the desert about game or enemies, belong to codes of gesture-signals identical in principle, and to a great extent independent both of nationality and education; there is even a natural syntax, or order of succession, in such gesture-signs. To these gestures let there be added the use of the interjectional cries, such as *oh! ugh! hey!* and imitative sounds to represent the cat's *mew*, the *click* of a trigger, the *clap* or *thud* of a blow, &c. The total result of this combination of gesture and significant sound will be a general system of expression, imperfect but serviceable, and naturally intelligible to all mankind without distinction of race. Nor is such a system of communication only theoretically conceivable; it is, and always has been, in practical operation between people ignorant of one another's language, and as such is largely used in the intercourse of savage tribes. It is true that to some extent these means of utterance are common to the lower animals, the power of expressing emotion by cries and tones extending far down in the scale of animal life, while rudimentary gesture-signs are made by various mammals and birds. Still, the lower animals make no approach to the human system of natural utterance by gesture-signs and emotional-imitative sounds, while the practical identity of this human system among races physically so unlike as the Englishman and the native of the Australian bush, indicates extreme closeness of mental similarity throughout the human species.

Variety of language.

When, however, the Englishman and the Australian speak each in his native tongue, only such words as belong to the interjectional and imitative classes will be naturally intelligible, and as it were instinctive to both. Thus the savage, uttering the sound *waow!* as an explanation of surprise and warning, might be answered by the white man with the not less evidently significant *sh!* of silence, and the two speakers would be on common ground when the native indicated by the name *bwirri* his cudgel, flung *whirring* through the air at a flock of birds, or when the native described as a *jakkal-yakkal* the bird called by the foreigner a *cockatoo*. With these, and other very limited classes of natural words, however, resemblance in vocabulary practically ceases. The Australian and English languages each consist mainly of a series of words having no apparent connection with the ideas they signify, and differing utterly; of course, accidental coincidences and borrowed words must be excluded from such comparisons. It would be easy to enumerate other languages of the world, such as Basque, Turkish, Hebrew, Malay, Mexican, all devoid of traceable resemblance to Australian and English, and to one another. There is, moreover, extreme difference in the grammatical structure both of words and sentences in various languages. The question then arises, how far the employment of different vocabularies, and that to a great extent on different grammatical principles, is compatible with similarity of the speakers' minds, or how far does diversity of speech indicate diversity of mental nature? The obvious answer is, that the power of using words as signs to express thoughts with which their sound does not directly connect them, in fact as arbitrary symbols, is the highest grade of the special human faculty in language, the presence of which binds together all races of mankind in substantial mental unity. The measure of this unity is, that any child of any race can be brought up to speak the language of any other race.

Difference of vocabulary and grammatical structure.

To ascertain the causes to which languages owe their unlikeness in material and structure, how far to essential differences of mental type among the races of mankind, and how far to minor causes of variation, which may be called secondary, is a problem of extreme difficulty, towards the precise solution of which little has yet been done. One of the most remarkable of linguistic differences is the tendency of some languages to isolate their words, and of others to form elaborate inflexions. The extremes may be seen, on the one hand, in an ordinary Chinese sentence of isolated monosyllables, such as "*yu tsze nien chiu tsin, tung chu*," &c., *i.e.*, "in this year autumn ended, winter begun," &c.; and, on the other hand, in one of the monstrous polysyllables into which the Greenlanders will agglutinate a whole phrase, *inilertorniarpatdlăsarqôrpâ*, *i.e.*, "he will probably try too much to get it done soon." Among languages which form grammatical combinations or inflexions, the modes of so doing are as various as possible. Thus, in Africa, the Hottentot noun forms its plural by a suffix, as *khoi*, "man;" *khoin*, "men:" while the Zulu employs prefixes to distinguish its numbers, as *umu-ntu*, "a man;" *aba-ntu*, "men." The Dinka may supply examples of forming the plural by internal change, *ran*, "man;" *ror*, "men." Nor are the differences of syntax in different tongues less absolute. In non-inflecting languages one of the most vital points is the relative position of two nouns, of which the one stands as substantive, and the other as defining it by an attribute. This may be illustrated by English compounds, such as *work-house* and *house-work*. Here our rule is to place the attribute-noun first, while, of two neighbouring languages of Asia, the Burmese and the Siamese, the one settles this question in our way, the other in exactly the opposite. The Siamese expression for sailors, *luk rua*, means "sons of the ship," just as the Burmese expression for villagers, *rwa tha*, means "children of the village;" but in the first case the construction is "sons ship," whereas in the second it is "village children." Again, for reasons not yet fully explained, some languages place the adjective before the substantive, as Chinese *pe ma*, "white horse;" while other languages reverse this construction, as Maori, *rakau roa*, "tree long" (*i.e.*, tall tree). These are but examples of possible divergences in linguistic structure, and no prudent ethnologist would assert that racial peculiarities have nothing to do with such various tendencies. At the same time, there is no proof but that they may have resulted from historical circumstances more or less independently of race. Our own Aryan family of nations and languages affords what must always be prominent evidence in this argument. It is acknowledged that Sanskrit, Russian, Greek, Latin, Welsh, English, &c., are, philologically speaking, dialects of a single Aryan speech, which no doubt at some ancient period was spoken by a single tribe or nation. Yet the languages sprung from this original Aryan tongue, by various courses of development and accretion, are mutually unintelligible. If a Greek sentence be taken at random, such as this, "Οὐ χρὴ παννύχιον εὕδειν βουληφόρον ἄνδρα," and it be translated even too verbally into English, "A counsel-bearing man ought not to sleep all night," the traces of linguistic connection between the Greek and English words (*phoros*, *bear; nux*, *night*) are hardly perceptible except to philologists. Even the essential character of the two languages is seen to be different, for the construction of the Greek sentence depends mainly on the inflexions of the words, while in English such inflexions are almost discarded, and their effect is produced by the syntax and the auxiliary particles. Moreover, as to some most important points of syntax, Aryan languages differ widely from one another; thus, to use a familiar instance, French and English take contradictory lines as to the relative position of the adjective and substantive, as also of the object-pronoun and verb,—"*c'est un cheval blanc, je le vois*," "it is a white horse, I see him." So Hindustani and English, though both Aryan tongues, reverse the positions of the verb and object, as "*ghorā lāo*" ("horse bring"), *i.e.*, "bring the horse!" Thus on the whole, the endless variety in vocabulary and structure among the languages of the world affords important evidence as to the mental diversities of the nations speaking those languages. But the unity of the faculty of speech in man stands as the primary fact, while the character of the grammar and dictionary belonging to any one nation represents only a secondary fact, such as might be fairly set down as resulting from their particular stage and circumstances of linguistic development.

Families of language.

The principles of the development of a family of languages from a single parent tongue are laid down elsewhere. (See LANGUAGE.) It has here to be noticed that the evidence on which such linguistic groups may be treated as allied by descent is of various degrees of fulness and strength. The most perfect available case is that of the

Romance languages, comprising Italian, Spanish, French, &c.; inasmuch as not only does the classic Latin remain substantially the representative of their common original, but the very stages of their development from it are preserved in documents of successive ages. Thus, in comparing the vocabularies of Italian and French, it is, in the first place, seen that they to a great extent correspond,—this correspondence extending to words which one language is least likely to borrow from another, viz., pronouns, the lower numerals, and names of the most universal and familiar objects. It is only, however, by etymological analysis that their depth of correspondence comes fully into view, it being seen that the ultimate elements or roots are largely common to the two languages, as are also the grammatical affixes by which words are formed from these roots, while general similarity of linguistic structure pervades both tongues. Such intimate correspondence could only result from derivation from a common parent language, which in this case exists in Latin. In other groups of languages the existence of the common parent may be inferred from correspondence of this highest order. Thus there must have existed, at some period, what may be called the parent Slavonic, whence descend the Russian, Polish, Bohemian, &c.; and the parent Keltic, whence descend Welsh, Gaelic, Breton, &c., while behind the various branches of the whole Aryan family are dimly to be discerned the outlines of a primitive Aryan speech. In like manner, a comparison of the Arabic, Hebrew, Syriac, &c., shows that these must be all derived from a primitive Semitic speech, containing many of the simple root forms, which still exist in its modern descendants, and being already characterised by the principle of internal inflexion. Beyond the limits of these two, the most important linguistic families, various others have been satisfactorily made out, though hardly with the same completeness of proof. In the Turanian or Tatar family are included the Turkish, Mongol, Hungarian, Finnish, Ostyak, &c.; the Dravidian family takes in the Tamil, Telugu, and various other South Indian dialects; the Polynesian family comprises the languages of the higher race of the South Sea Islands; the Negro-Kafir family consists of the prefixing languages spoken by most African tribes from the equatorial regions southward; the Guarani family in South America, the Algonquin and Athapascan families in North America, and the Australian family, each includes a number of tribes ranging over a vast extent of territory, and so on. As to smaller divisions, it is common for languages to occur in groups of several connected dialects, though not forming part of one of the wider linguistic families; thus the Aztec and Nicaraguan are closely related dialects, as are the Quichua and Aymara, while what philologists describe as isolated languages, as the Basque appears to be, are rather isolated groups of dialects, with no known analogues beyond a limited district.

If the present state of the philological classification of mankind be compared with that of half a century ago, it will be seen that much progress has been made in referring groups of languages each to a common ancestral tongue. At the same time, greater cogency of proof is now demanded in such classification. The method of comparing a short vocabulary of twenty words or so in two languages is now abandoned, for where an extensive connection really exists, this is much better proved by a systematic comparison, while a few imperfect resemblances in the two lists might be due to accident, or the adoption of words. Nothing short of a similarity in the roots or elements of two languages, as well as in their grammatical structure, too strong to be explained by any independent causes, is now admitted as valid proof of common descent. This limitation, however, by no means amounts to a denial of the possibility of such descent. Thus it is often argued, on the strength of some similarities between Hebrew and Indo-European roots, that the two so distinct Semitic and Aryan families of language are themselves sprung from some yet more remotely ancient tongue. Thus also it has been attempted to connect the Malay and Tatar groups of languages. Either or both of these opinions may be true; but the general verdict of philologists is, that they are not satisfactorily made out, and therefore cannot be recognised.

Primitive languages

Under the present standard of evidence in comparing languages and tracing allied groups to a common origin, the crude speculations as to a single primeval language of mankind, which formerly occupied so much attention, are acknowledged to be worthless. Increased knowledge and accuracy of method have as yet only left the way open to the most widely divergent suppositions. For all that known dialects prove to the contrary, on the other hand, there may have been one primitive language, from which the descendant languages have varied so widely, that neither their words nor their formation now indicate their unity in long past ages, while, on the other hand, the primitive tongues of mankind may have been numerous, and the extreme unlikeness of such languages as Basque, Chinese, Peruvian, Hottentot, and Sanskrit, may arise from absolute independence of origin.

Language and race.

The language spoken by any tribe or nation is not of itself absolute evidence as to its race-affinities. This is clearly shown in extreme cases. Thus the Jews in Europe have almost lost the use of Hebrew, but speak as their vernacular the language of their adopted nation, whatever it may be; even the Jewish-German dialect, though consisting so largely of Hebrew words, is philologically German, as any sentence shows: "*Ich hab noch hojom lo geachelt,*" "I have not yet eaten to-day." The mixture of the Israelites in Europe by marriage with other nations is probably much greater than is acknowledged by them; yet, on the whole, the race has been preserved with extraordinary strictness, as its physical characteristics sufficiently show. Language thus here fails conspicuously as a test of race, and even of national history. Not much less conclusive is the case of the predominantly Negro populations of the West India Islands, who, nevertheless, speak as their native tongues dialects of English or French, in which the number of intermingled native African words is very scanty: "*Dem hitti netti na ini watra bikasi dem de fisiman,*" "They cast a net into the water, because they were fishermen." (Surinam Negro-Eng.) "*Bef pas ca jamain lasse poter cones li;*" "Le bœuf n'est jamais las de porter ses cornes." (Haytian Negro-Fr.) If it be objected that the linguistic conditions of these two races are more artificial than has been usual in the history of the world, less extreme cases may be seen in countries where the ordinary results of conquest-colonisation have taken place. The Mestizos, who form so large a fraction of the population of modern Mexico, numbering several millions, afford a convenient test in this respect, inasmuch as their intermediate complexion separates them from both their ancestral races, the Spaniard, and the chocolate-brown indigenous Aztec, or other Mexican. The mother-tongue of this mixed race is Spanish, with an infusion of Mexican words; and a large proportion cannot speak any native dialect. In most or all nations of mankind, crossing or intermarriage of races has thus taken place between the conquering invader and the conquered native, so that the language spoken by the nation may represent the results of conquest as much or more than of ancestry. The supersession of the Keltic Cornish by English, and of the Slavonic Old-Prussian by German, are but examples of a process which has for untold ages been supplanting native dialects, whose very names have mostly disappeared. On the other hand, the language of the warlike invader or peaceful immigrant may yield, in a few generations, to the tongue of the mass of the population, as the Northman's was replaced by French, and modern German gives way to English in the United States. Judging, then, by the extirpation and adoption of languages within the range of history, it is obvious that to classify mankind into races, Aryan, Semitic, Turanian, Polynesian, Kafir, &c., on the mere evidence of language, is an intrinsically unsound method. From the earliest times in which nations have been classified by languages, its unrestricted use has vitiated sound ethnology.

Nevertheless, under proper restrictions, speech affords information as to the affinities of races only second in value to that derived from physical characteristics. As a rule, language at least proves some proportion of ancestry. It could hardly happen that one people should come into so close a relation to another as to supplant its language, without strong intermixture of race in the next generation. This is true in the extreme case of the West Indian coloured population, among whom the majority are now crossed with European blood, so that in each succeeding generation the proportion of absolutely pure Negro families becomes less. Still more fully is it true of coloured races in Mexico or Brazil, whose Spanish or Portuguese language represents at least a large European element of ancestry. Thus in India many millions of people, whose blood is predominantly that of the darker indigenous race, nevertheless speak dialects of the languages of the fairer Aryans; but then they are for the most part distinctly mixed races of partly Aryan ancestry. With these facts before us, it is not difficult to determine the principles on which the ethnologist may use language as partial evidence of race. In the first place, it strengthens the evidence of bodily characters. Thus in South Africa the Zulu seems by colour, features, shape of skull, &c., to be, if not an absolute Negro, of a mixed and modified Negro type. This view of his origin is strengthened by the fact that the Zulu language belongs to the peculiar prefixing family which extends so widely among the Negro nations farther north. So the Hottentot language, in its evident connection with that of the Bushmen, adds its weight to the physical argument, that these two are descendants more or less mixed and varied from a single race, small, yellow, crisp-haired, and speaking an inflectional monosyllabic language, articulated with clicks. In the second place, language may prove race-connection where bodily characteristics, though they do not contradict, do not suffice. Thus, comparing the dark Andalusian with the fair Swede, we ask the question, whether there is distinguishable common parentage between these two varieties of the white man? The anatomist might hesitate here. Nor, indeed, is the physical problem nearly solved, but at least a partial solution is involved in the philologist's proof that the two peoples speak languages inherited at some remote period from a common Aryan tongue, and must therefore have had a common element in their ancestry of at least sufficient strength to carry language with it. Thus each linguistic family affords at least partial evidence of race, proving, for instance, the existence of a common ancestry of the Irishman and the Russian, of the Jew and the Maltese, of the Tahitian and the Malagasy, though in such pairs of races the actual amount of common ancestry may be less than that of the different race-elements with which it has combined.

Language and culture.

As regards political nationality and the history of civilisation, the evidence of speech is of still greater weight. In many cases of the mixture of nations the language of the dominant civilisation prevails, as where Latin dialects superseded the native tongues in Western Europe, and Germanic languages encroached on Turanian in Finland, on Slavonic in Russia, and on Keltic in the Scotch Highlands. In other cases, where one nation has received elements of civilisation from another, language is apt to keep record of the process by adopting foreign words and ideas together. Thus the language of the barbarian Turks has absorbed masses of Arabic, which itself had in like manner absorbed Persian, when Persia was the fountain-head of early Moslem culture. In the same manner Dravidian languages of South India have been saturated with words and phrases from Sanskrit and its related dialects, so that a page of Tamil literature is of itself the proof of a non-Aryan race having received from an Aryan race a whole system of religion, philosophy, and social order. The most extreme cases of such verbal indication of foreign influence are to be found in languages of low races of America and the Pacific, which have adopted from European languages not only terms for imported arts and ideas, but names of such numerals as 6 and 7, previously expressed by more clumsy native combinations. Thus the language of any people, though less effective than was once believed as a means of determining its place in the classified order of mankind, does, to some extent, indicate its physical, and, to a still greater extent, its intellectual ancestry.

Stages of civilisation.

VI. *Development of Civilisation.*—The conditions of man at the lowest and highest known levels of culture are separated by a vast interval; but this interval is so nearly filled by known intermediate stages, that the line of continuity between the lowest savagery and the highest civilisation is unbroken at any critical point. The Australians and forest Indians of Brazil may be taken as the lowest modern savages whose thought and life have been investigated with any thoroughness; while other less accurately-studied tribes are in some respects inferior even to these. An examination of the details of savage life shows not only that there is an immeasurable difference between the rudest man and the highest lower animal, but also that the least cultured savages have themselves advanced far beyond the lowest intellectual and moral state at which human tribes can be conceived as capable of existing, when placed under favourable circumstances of warm climate, abundant food, and security from too severe destructive influences. In fact, the Australian or Brazilian savage has already attained to rudimentary stages in many of the characteristic functions of civilised life. His language, expressing thoughts by conventional articulate sounds, is the same in essential principle as the most cultivated philosophic dialect, only less exact and copious. His weapons, tools, and other appliances, such as the hammer, hatchet, spear, knife, awl, thread, net, canoe, &c., are the evident rudimentary analogues of what still remains in use among Europeans. His structures, such as the hut, fence, stockade, earthwork, &c., may be poor and clumsy, but they are of the same nature as our own. In the simple arts of broiling and roasting meat, the use of hides and furs for covering, the plaiting of mats and baskets, the devices of hunting, trapping, and fishing, the pleasure taken in personal ornament, the touches of artistic decoration on objects of daily use, the savage differs in degree but not in kind from the civilised man. The domestic and social affections, the kindly care of the young and the old, some acknowledgment of marital and parental obligation, the duty of mutual defence in the tribe, the authority of the elders, and general respect to traditional custom as the regulator of life and duty, are more or less well marked in every savage tribe which is not disorganised and falling to pieces. Lastly, there is usually to be discerned amongst such lower races a belief in unseen powers pervading the universe, this belief shaping itself into an animistic or spiritualistic theology, mostly resulting in some kind of worship. If, again, high savage or low barbaric types be selected, as among the North American Indians, Polynesians, and Kafirs of South Africa, the same elements of culture appear, but at a more advanced stage, namely, a more full and accurate language, more knowledge of the laws of nature, more serviceable implements, more perfect industrial processes, more definite and fixed social order and frame of government, more systematic and philosophic schemes of religion, and a more elaborate and ceremonial worship. At intervals new arts and ideas appear, such as agriculture and pasturage, the manufacture of pottery, the use of metal implements, and the device of record and communication by picture-writing. Along such stages of improvement and invention the bridge is fairly made between savage and barbaric culture; and this once attained to, the remainder of the series of stages of civilisation lies within the range of common knowledge.

Development theory.

The teaching of history, during the three to four thousand years of which contemporary chronicles have been preserved, is that civilisation is gradually developed in the course of ages by enlargement and increased precision of knowledge, invention and improvement of arts, and the progression of social and political habits and institutions towards general well-being. The conditions of such races as the older Jews, Greeks, and Germans, are known to us by ancient chronicles, and by poetry and myth even more valuable than chronicle in the details they unconsciously preserve of the state of society at the time whence they have been handed down. Starting from the recorded condition of such barbaric nations, and following the general course of culture into the modern world, all the great processes of mental and social development may be seen at work. Falling back or decay also takes place, but only to a limited extent destroys the results of growth in culture. It is thus matter of actual record, that the ancestors of civilised nations were barbaric tribes, and the inference seems reasonable that the same process of development had gone on during previous ages outside the domain of direct history, so that barbaric culture itself arose out of an earlier and ruder condition of primitive culture, more or less corresponding with the state of modern savage tribes. The failure of direct record of this passage from savagery upward to barbarism was to be expected from the circumstances of the case. No people civilised enough to preserve history could have watched the age-long process of a savage tribe developing its culture; indeed, experience shows that independent progress could hardly have taken place among an uncivilised in contact with a civilised race. Nor could a barbaric nation, though it had really and independently risen from savagery within some few thousand years, give any valid account of this gradual advancement, for the very reason of its having taken place while the nation was yet in, or but little removed from, the savage state, one part of the very definition of which is that it has no trustworthy means of preserving the history of events even for a single century, much less for the long period required for so vast a development. This view of the low origin and progressive development of civilisation was already held in ancient times, as in the well-known speculations of the Epicurean school on the condition of the earliest men, who roved like wild animals, seeking their food from the uncultured earth, till arts and social laws arose among them (Lucret., *De Rerum Nat.*, v. 923; Horat., *Sat.*, i. 3); or where the like idea has taken in China the form of ancient legend, recording the time when their nation was taught to use skins for clothing, to make fire, and to dwell in houses (Pauthier, *Livres Sacrés de l'Orient*, p. 26). In opposition to such views of primeval rudeness, traditions of a pristine state of human excellence have long been cherished, such as the "golden age" (Hesiod., *Op. et Dies*, 108). Till of late wide acceptance has been given to arguments, partly based on theological and partly on anthropological grounds, as to man's incapability of rising from a savage state, and the consequent necessity of a supernatural bestowal of culture on the first men, from whose high level savages are supposed by advocates of this theory to have degenerated. The anthropological evidence adduced in support of this doctrine is, however, too weak for citation, and even obviously erroneous arguments have been relied on (see, for example, Archbishop Whately, *Essay on the Origin of Civilisation*, and remarks on its evidence in Tylor, *Early Hist. of Man.*, p. 163). It has been especially the evidence of prehistoric archæology which, within the last few years, has given to the natural development-theory of civilisation a predominance hardly disputed on anthropological grounds. The stone implements, which form the staple proof of man's existence at the period of the river-drift, are of extreme rudeness as compared even with ordinary savage types, so that it is obvious that the most ancient known tribes were, as to the industrial arts, at a low savage level. The remains in the caverns justify this opinion, especially where in central France more precision is given to the idea of prehistoric life by the discovery of bone weapons for hunting and fishing, which suggest a rude condition resembling that of the Esquimaux (see the preceding section IV., *Antiquity of Man*). The finding of ancient stone implements buried in the ground in almost every habitable district of the world, including the seats of the great ancient civilisations, such as Egypt, Assyria, India, China, Greece, &c., may be adduced to show that the inhabitants of these regions had at some time belonged to the stone age. This argument goes far to prove that the ancestors of all nations, high and low, were once in that uncultured condition as to knowledge, arts, and manners generally, which within our experience accompanies the use of stone implements and the want of metals. No valid refutation of this reasoning has been offered, and it is corroborated by arguments to be drawn from study of the facts of civilisation, of which some will be here mentioned for their bearing on the theory of development.

Historic development of culture.

History shows how development of the arts takes place by efforts of skill and insight, as where Phidias rose above the clumsier sculptors of the time before him, or where the earliest gnomon—a mere staff set up in order to have its shadow measured—passed into the graduated sun-dial; or adaptations of old contrivances produce new results, as when the ancient Pan's pipes, blown by a bellows, became the organ, when the earlier block-printing led up to the use of movable types, and when the magnetic-needle was taken out of the mariner's compass to find a new office on the telegraph-dial; or lastly, more absolutely original inventions arise, the triumphs of the scientific imagination, such as the pendulum and the steam-engine. In the evolution of science the new knowledge ever starts from the old, whether its results be to improve, to shift, or to supersede it. The history of astronomy extends far enough back to show its barbaric stages, when the earth was regarded as a flat surface, over-arched by a solid dome or firmament; and when not only was the sun considered to move round the earth, but its motions, as well as the moon's, were referred to the guidance and even the impulse of personal deities. Beginning with this first stage of the science, there lies before us the whole record of the exacter observation and closer reasoning which have gradually replaced these childlike savage conceptions by the most perfect of physical theories. Thus, again, the history of medicine shows improvement after improvement on the rude surgical appliances and the meagre list of efficient drugs which the barbaric leech had at his disposal, while its theory has changed even more absolutely than its practice; for medical history begins with the ancient world holding fast to the savage doctrine that madness, epilepsy, fever, and other diseases, are caused by demons possessing the patient—a belief which is still that of half the human race, but which it has been the slow but successful task of scientific pathology to supersede in the civilised world. In like manner, the history of judicial and administrative institutions may be appealed to for illustrations of the modes in which old social formations are reshaped to meet new requirements, new regulations are made, and new officers are constituted to perform the more complex duties of modern society, while from time to time institutions of past ages, which have lost their original purpose, and become obsolete or hurtful, are swept away.

Prehistoric development of culture.

That processes of development similar to these had already been effective to raise culture from the savage to the barbaric level, two considerations especially tend to prove. First, there are numerous points in the culture even of rude races which are not explicable otherwise than on the theory of development. Thus, though difficult or superfluous arts may easily be lost, it is hard to imagine the abandonment of contrivances of practical daily utility, where little skill is required, and materials are easily accessible. Had the Australians or New Zealanders, for instance, ever possessed the potter's art, they could hardly have forgotten it. The inference that these tribes represent the stage of culture before the invention of pottery is confirmed by the absence of buried fragments of pottery in the districts they inhabit (Lubbock, in *Report of British Association*, Dundee, 1867, p. 121). The same races who were found making thread by the laborious process of twisting with the hand, would hardly have disused, if they had ever possessed it, so simple a labour-saving device as the spindle, which consists merely of a small stick weighted at one end; the spindle may, accordingly, be regarded as an instrument invented somewhere between the lowest and highest savage levels (Tylor, *Early Hist. of Mankind*, p. 193). Again, many devices of civilisation bear unmistakable marks of derivation from a lower source; thus the ancient Egyptian and Assyrian harps, which differ from ours in having no front pillar, appear certainly to owe this remarkable defect to having grown up through intermediate forms from the simple strung bow, the still used type of the most primitive stringed instrument (Engel, *Music of the most Ancient Nations*, pp. 17, 30). In this way the history of numeral words furnishes actual proof of that independent intellectual progress among savage tribes which some writers have rashly denied. Such words as *hand*, *hands*, *foot*, *man*, &c., are used as numerals signifying 5, 10, 15, 20, &c., among many savage and barbaric peoples; thus Polynesian *lima*, *i.e.*, "hand," means 5; Zulu, *tatisitupa*, *i.e.*, "taking the thumb," means 6; Greenlandish, *arfersanek-pingasut*, *i.e.*, "on the other foot three," means 18; Tamanac, *tevin itoto*, *i.e.*, "one man," means 20, &c., &c. The existence of such expressions demonstrates that the people who use them had originally no spoken names for these numbers, but once merely counted them by gesture on their fingers and toes in low savage fashion, till they obtained higher numerals by the inventive process of describing in words these counting-gestures (Tylor, in *Journal Royal Inst.*, March 15, 1867; *Primitive Culture*, chap. vii.)

Survival in culture.

Second, the process of "survival in culture" has caused the preservation in each stage of society of phenomena belonging to an earlier period, but kept up by force of custom into the later, thus supplying evidence of the modern condition being derived from the ancient. Thus the mitre over an English bishop's coat-of-arms is a survival which indicates him as the successor of bishops who actually wore mitres, while armorial bearings themselves, and the whole craft of heraldry, are survivals bearing record of a state of warfare and social order whence our present state was by vast modification evolved. Evidence of this class, proving the derivation of modern civilisation, not only from ancient barbarism, but beyond this, from primeval savagery, is immensely plentiful, especially in rites and ceremonies, where the survival of ancient habits is peculiarly favoured. Thus the modern Hindu, though using civilised means for lighting his household fire, retains the savage "fire-drill" for obtaining fire by friction of wood when what he considers pure or sacred fire has to be produced for sacrificial purposes; while in Europe into modern times the same primitive process has been kept up in producing the sacred and magical "need-fire," which was lighted to deliver cattle from a murrain. Again, the funeral offerings of food, clothing, weapons, &c., to the dead are absolutely intelligible and purposeful among savage races, who believe that the souls of the departed are ethereal beings, capable of consuming food, and of receiving and using the souls or phantoms of any objects sacrificed for their use. The primitive philosophy to which these conceptions belong has to a great degree been discredited by modern science; yet the clear survivals of such ancient and savage rites may still be seen in Europe, where the Bretons leave the remains of the All Souls' supper on the table for the ghosts of the dead kinsfolk to partake of, and Russian peasants set out cakes for the ancestral manes on the ledge which supports the holy pictures, and make dough ladders to assist the ghosts of the dead to ascend out of their graves and start on their journey for the future world; while other provision for the same spiritual journey is made when the coin is still put in the hand of the corpse at an Irish wake. In like manner magic still exists in the civilised world as a survival from the savage and barbaric times to which it originally belongs, and in which is found the natural source and proper home of utterly savage practices still carried on by ignorant peasants in our own country, such as taking omens from the cries of animals, or bewitching an enemy by sticking full of pins and hanging up to shrivel in the smoke an image or other object, that similar destruction may fall on the hated person represented by the symbol (Tylor, *Primitive Culture*, chap. i., iii., iv., xi., xii.; *Early Hist. of Man*, chap. vi.)

General lines of development.

To conclude, the comparative science of civilisation thus not only generalises the data of history, but supplements its information by laying down the lines of development along which the lowest prehistoric culture has gradually risen to the highest modern level. Among the most clearly marked of these lines is that which follows the succession of the stone, bronze, and iron ages. The stone age represents the early condition of mankind in general, and has remained in savage districts up to modern times, while the introduction of metals need not at once supersede the use of the old stone hatchets and arrows, which have often long continued in dwindling survival by the side of the new bronze and even iron ones. The bronze age had its most important place among ancient nations of Asia and Europe, and among them was only succeeded after many centuries by the iron age; while in other districts, such as Polynesia and Central and South Africa, and America (except Mexico and Peru), the native tribes were moved directly from the stone to the iron age without passing through the bronze age at all. Although the three divisions of savage, barbaric, and civilised man do not correspond at all perfectly with the stone, bronze, and iron ages, the classification of civilisation thus introduced by Nilsson and Thomsen has proved a guide of extraordinary value in arranging in their proper order of culture the nations of the Old World. Another great line of progress has been followed by tribes passing from the primitive state of the wild hunter, fisher, and fruit-gatherer to that of the settled tiller of the soil, for to this change of habit may be plainly in great part traced the expansion of industrial arts and the creation of higher social and political institutions. These, again, have followed their proper lines along the course of time. Among such are the immense legal development by which the primitive law of personal vengeance passed gradually away, leaving but a few surviving relics in the modern civilised world, and being replaced by the higher doctrine that crime is an offence against society, to be repressed for the public good. Another vast social change has been that from the patriarchal condition, in which the unit is the family under the despotic rule of its head, to the systems in which individuals make up a society whose government is centralised in a chief or king. In the growth of systematic civilisation, the art of writing has had an influence so intense, that of all tests to distinguish the barbaric from the civilised state, none is so generally affective as this, whether they have but the failing link with the past which mere memory furnishes, or can have recourse to written records of past history and written constitutions of present order. Lastly, still following the main lines of human culture, the primitive germs of religious institutions have to be traced in the childish faith and rude rites of savage life, and thence followed in their expansion into the vast systems administered by patriarchs and priests, henceforth taking under their charge the precepts of morality, and enforcing them under divine sanction, while also exercising in political life an authority beside or above the civil law. These illustrations may suffice to make it clear that although the science of culture is still but rudimentary and imperfect, it indicates the one sound and indispensable method for the study of human arts and institutions, that of placing each at its proper stage in a line of evolution, and explaining it by the action of new conditions upon the previous stage whence it was derived. (E. B. T.)

ANTHROPOMORPHISM is a term used in theological writings to denote the figure by which words expressing human organs and activities are applied to the divine Being; in short, it is the conception and representation of God as possessed of corporeal and human properties. Originally and literally the word implied only the ascribing to God a physical form resembling the human body, and consequently included under it all forms of expression which attribute to Him the exercise of physical organs and senses. But its meaning was soon extended so as to comprehend all representations of God which require Him either to be in himself corporeally extended, or to possess a corporeal body as the necessary condition of His activity. In this wider sense all theories were designated anthropomorphic, which identified God with light or the physical universe, or which placed alongside of Him a primeval, uncreated matter.

Primitive ideas of God are necessarily framed by man from the analogy of his own nature. He is, however, able to represent God to himself under the analogy of his mental or spiritual, as well as under that of his material nature. This more refined form was called anthropopathism, and is that mode of contemplating the divine attributes founded on the analogy of God to the human spirit. All forms of expression which ascribe to God passions, intelligence, or volition, rest ultimately upon this supposed analogy. In modern theology and philosophy, it is this mode of thought that usually receives the name of anthropomorphism.

Anthropomorphism is inseparable from early religion. The first dim intuition of God as the ruler of the universe, on whom we depend, cannot at an early time be seized in all its purity by reason. Sense and imagination are developed before reason, and in semi-barbarous intelligences completely overbalance it. The object of their faith is not God himself, but God as manifested in nature and history. It is only through ideas derived from sensible objects and elevated by the imagination that man can clothe his primitive thought of God with attributes that enable him to realise it, to bring it home to himself. He must represent God as in all respects like himself, superior only in power. The very words by which alone he can give expression to the first workings of his consciousness of God carry with them a sensible meaning, and hence react powerfully on the development of his belief. They imperceptibly fix attention upon the physical facts involved in them, and their merely symbolic use is forgotten. Hence arise myths. Even among peoples in whom the growth of the religious consciousness was extraordinarily favoured, strong traces of anthropomorphism are to be found. In the Hebrew literature there is a prevailing anthropomorphic idea of God. He is represented as seeing, hearing, smelling; as having a visible, corporeal presence; as hating, loving, and repenting. Although the pure idea of God as a spirit, as the very essence of being, is distinctly recognised and insisted upon by the prophets and lawgivers, the people demanded a visible symbol, a sensible emblem of their faith. Great part of the ceremonial law is taken up with the attempt to reconcile this desire for visible symbol with the purer requirements of their faith. Christian thought freed itself completely from the yoke of this crude anthropomorphism by its fundamental axiom that God is a spirit. Theology since then has had to steer its course with care between two opposite tendencies: one striving to attain to a living personal community with God through Christ, and thereby running the risk of introducing foreign elements into the idea of God; the other, from undue fear of anthropomorphism, tending to reduce the idea of God to a blank negation, a substance without qualities. In the history of the church these tendencies appeared at a very early period. In the Clementine homilies, but particularly in Tertullian (see *Adv. Praxean*, c. vii.; *De Carne Christi*, c. xi.) there is distinct anthropomorphism. Tertullian declares that nothing can have real being that is not extended, corporeal; God, therefore, he seems to identify with an ethereal being of light. An example of the finer form in which human affections are ascribed to God may be found in Lactantius (*De Ira Dei*, c. ii.) The Alexandrian theologians, from their philosophical training, were specially opposed to anthropomorphism, but in their hands the danger of the opposite tendency is seen. According to some of them, we know God only by negation,—we know what He is not, not what He is. Others (*e.g.*, Irenæus, Novatian) declare that all the predicates of God are only in image; and that, from the finitude of our minds, we must use terms expressing not God's nature, but our own ignorance. Phrases in Scripture which seemed to be anthropomorphic were explained by the Fathers as revelations of God in such a way as to be intelligible to us. This revelation was called (see Chrysostom, *Hom.* iii. c. 3) condescension or divine economy.

The church itself was not free from anthropomorphism of the crudest type. In the 2d century Melito, bishop of Sardis, wrote a book concerning the corporeity of God; and in the 4th century Audæus, in Mesopotamia, held similar views, and had many followers. In the Middle Ages the question gradually merged into the more philosophical one of the relation between reason and faith. In modern theology the problem again appears, but its aspect is completely philosophical. Philosophy, indeed, has never ceased to concern itself with this very question. Xenophanes mocked the anthropomorphism of his countrymen; Aristotle denied to the gods ethical virtue and the possession of emotions or passions; he allowed to them only a life of intellectual speculation. The Epicureans thought the gods lived in complete quiescence, and concerned themselves not at all with the affairs of men (see Lucretius, ii. 646). Philo exhibits very strongly the tendency to reduce the Deity to a lifeless abstraction, whose attributes are only negatively known. In modern philosophy, Descartes attempted to settle the problem, by affirming that any attributes in us which involve limitation or imperfection cannot be ascribed to God, but that attributes which do not imply imperfection can be predicated of Him. Spinoza is one of the strongest opponents of any form of anthropomorphism, and from him the modern aspect of the question may be said to proceed. He brought clearly to light the fundamental difficulty, the reconciliation of the infinite and absolute nature of God with any attribute whatsoever; for attribute, as such, implies negation, *i.e.*, limitation. Spinoza dismisses as anthropomorphic the idea of God as an intelligence, as free to act, and as ruling the world, and thus destroys the ideas of design in nature and of providence. The consequences of this theory on questions relating to the personality of God, miracles, prayer, &c., have been worked out very fully in the most recent times.

Thus the real problem at the root of the question as to the legitimacy of anthropomorphic modes of thought, is the philosophical one of the limits of human intelligence, of the relation between the divine thought in itself and in nature and human intelligence. A long line of philosophic thinkers affirm the impossibility of human intelligence penetrating the nature of the divine, and point out our inability to solve the many contradictions which arise in the attempt to do so. According to them, we can only think of God by analogy; our ideas of Him must be anthropomorphic, but they are at the same time known to be entirely symbolical. The best known representatives of this mode of thought are Bishop Browne and the late Dean Mansel.

ANTIBES, a seaport town of France, on the Mediterranean, in the arrondissement of Grasse, which formerly belonged to the department of Var, but which was transferred to the new department of Alpes Maritimes in 1860. The town is situated on the east side of a neck of land called La Garoupe, 10 miles S.E. of Grasse; it is fortified, and possesses a tolerable harbour, which accommodates a considerable fishing industry. The principal exports are dried fruits, salt fish, and oil. The surrounding country is very fertile, producing abundance of fruit and flowers. Antibes, the ancient *Antipolis*, was founded by colonists from Marseilles about 340 B.C. Population, 6004.

ANTICHRIST. Ἀντίχριστος, or ὁ ἀντίχριστος. The word occurs only in the first and second epistles of John. It signifies an opponent or adversary of Christ. The idea expressed by it had its origin in Judaism. According to prophetic anticipations, the Messianic time was to be immediately preceded by a great conflict, in which Jehovah would fight out of Zion for His own people, and defeat the concentrated opposition of the world. An Almighty leader on the one side seemed to require an antagonist on the other, a head of the army of darkness against the Prince of light. Thus Ezekiel depicts Gog proceeding out of Magog, to hazard a decisive battle against the Lord and His saints on the eve of the Messianic age (chapters xxxviii. and xxxix). The idea was subsequently embodied in Antiochus Epiphanes, who tried to eradicate Judaism with savage hatred. When we consider the insane violence he exhibited against the Jews and their temple, his prohibition of Jehovah's worship, the solemnisation of the Sabbath, and circumcision, it was natural to regard him as the representative of heathenism in its opposition to the true religion. Accordingly, the worshippers of Jehovah termed the small altar erected by him to Olympian Jove in the holy temple at Jerusalem (168 B.C.), the *abomination of desolation* (Daniel ix. 27, xi. 31, xii. 11; Mat. xxiv. 15). The apocalyptic visions of Daniel exerted an important influence upon the Jews after the time of Antiochus, animating them with hopes of the near approach of a better day, preceded, it is true, by a fearful struggle, in which a powerful prince, the impersonation of heathenism in its fiercest hate, should persecute the chosen people. The future of Israel was brightened by the visions of one whose predictions had been at least partially fulfilled. After this the idea seems to have been in abeyance till the reign of Caligula (40 A.D.), when Greeks in Alexandria and Syria attempted to introduce images of the emperor into the Jewish synagogues. The express command of Caligula addressed to the Jews, to erect his image in the temple at Jerusalem, in the form of Olympian Zeus, excited an intense commotion throughout Palestine, and must have recalled to the Jews familiar with their Scriptures the similar conduct of Antiochus, as though the prophet Daniel had foretold the blasphemy of the Roman emperor. In the discourse of Christ recorded by Matthew (chapter xxiv.), a personal opponent or antichrist does not appear, but the second advent is preceded by great affliction, the desecration of the temple, false Messiahs, and false apostles. This evangelic eschatology, however, appears in its present form to belong to a late redactor, so that it is difficult to separate Christ's own utterances from other elements probably incorporated with them. Various sayings of Jesus relative to his second appearing were evidently misapprehended or confused in the reminiscences of the early disciples.

St Paul resumes the idea of antichrist. Whatever Jewish conceptions he laid aside, and he emancipated himself from the grossest of them, he did not abandon the idea of an antichrist or terrible adversary of the true religion. The prophecies of Daniel, whether in their supposed relation to Antiochus or Caligula, and the impious command of the latter in particular to desecrate the Jewish temple, furnished him with traits for the portrait of Christ's great enemy, whose manifestation in the Roman empire the state of the world led him to suspect, especially as the empire was then identified by the Jews, as well as by Paul himself, with the fourth and last kingdom of Daniel's visions. Blending together the notions of an antichrist and false Christ, the picture which St Paul draws is that of the man of sin, "the son of perdition; who opposeth and exalteth himself above all that is called God, or that is worshipped; so that he as god sitteth in the temple of God, showing himself that he is God; the wicked one whose coming is after the working of Satan with all power and signs and lying wonders," &c. (2 Thess. ii. 3–9). Here the epithet ὁ ἄνομος appears to be borrowed from Isaiah xi. 4, the apostle coinciding with the Chaldee interpreter in understanding the passage of antichrist. The hindrance to the manifestation of the terrible enemy, to which Paul obscurely alludes, seems to be the Roman empire in one or other of its aspects; for we cannot adopt the ingenious conjecture that Claudius is meant, though the name fits the apostolic expression ὁ κατέχων, *qui claudit, Claudius.* Apart from the fact that the neuter τὸ κατέχον is used as well as the masculine it is scarcely probable that one whose reign was marked by cruel actions and bloodshed should be called the obstacle in the way of antichrist's manifestation. The apostle, not ignorant of Caligula's blasphemous edict, seems to have thought of some Cæsar in whom the persecuting power of heathenism should culminate, without pointing at either Claudius as the withholder, or Claudius's successor as the man of sin. The idea of antichrist was not historically fixed in his mind. Here we differ from Hitzig and Hausrath; though the date of the Thessalonian epistles (about 52 A.D.) presents no obstacle to the hypothesis, as De Wette thinks it does.

The author of the Revelation presents the antichrist idea in a more definite form than St Paul. Borrowing characteristic traits from Antiochus Epiphanes, perhaps too from Caligula, whose blasphemous order to set up his own image in the attitude of Olympian Zeus within the holy temple at Jerusalem created intense excitement throughout Palestine, aware of the fearful persecution which the Christians had suffered from Claudius's successor on the throne of the Cæsars, the apostle John makes the man of sin or antichrist to be Nero returning from the East, according to a report then current.[1] In his view the vicious cruelty of paganism had its incarnation in the monster who set fire to Rome, torturing the Christians there, and hesitating to commit no crime. If the capital of the heathen world had such a head, the character of the great antichrist stood forth in him. Accordingly, the writer describes Nero as the fifth head of the beast that rose out of the sea, *i.e.*, Rome, who received a deadly wound which was healed, who made war upon the saints and overcame them, who disappeared amid the wondering of the world, to return with renewed power for three years and a half. The number of the beast or head, 666, points unmistakably to Nero, for it is the equivalent of קסר נרון Kæsar Neron, נ = 50, = 200, ו = 6, נ = 50, ק = 100, ס = 60, ר = 200. He is the beast that was and is not, the fifth fallen head, one of the seven; the eighth, because he should reappear after his deadly wound was healed. The succession of emperors is Augustus, Tiberius, Caligula, Claudius, Nero, Galba. Renan has again sanctioned the reckoning of Julius Cæsar as the first of the list, on the authority of Josephus, Suetonius, Aurelius Victor,[2] &c.; but Suetonius's commencement of his lives of the Cæsars with Julius, is scarcely a valid proof of his reckoning him to be the first of the line. Tacitus, Aurelius Victor, and Sextus Rufus, not to speak of Hippolytus, favour the opinion that Augustus was the first emperor, and as the birth of Christ was under him, Christianity has nothing to do with Julius Cæsar. In the view of the apocalyptist the latter is of no importance. The apostle writing under Galba (68 A.D.), held the opinion then prevalent among Christians as well as others, that the emperor was not really dead, but was in the East, whence he would return with an army of Parthians to conquer and destroy Rome (Tacitus, *Hist.* ii. 8; Suetonius, *Nero*, cap. 57, Dio Chrysostom, *Or.* xxi.) Such belief had then taken possession of the minds not only of the Jewish Christians in Palestine, but of the Jews themselves, who were in a state of feverish excitement because Jerusalem was besieged. Terror had seized all worshippers of the true God, because of the aspect which the empire assumed (Revelation xiii. 3-8, 18, xvii. 11). The apocalyptist also states that false or antichristian prophetism was to unite with the healed beast, and cause men to worship him or be put to death (xiii. 14, 15). We assume that the second beast, which rises out of the earth as the first does out of the sea, is identical with the false prophet in xvi. 13, xix. 20, xx. 10, and that it is a personification of false or heathen prophesying with its soothsaying and auguries. But though Irenæus sanctions this view, it is not without difficulties, since the second beast ought in consistency to be historically definite like the first. It cannot be that the writer means the apostle Paul; for John, with all his Jewish tendencies, and hints unfavourable to Paul, would not speak so strongly against the latter. If John were not the author, as some incline to think, an unknown writer, with lively Judaic prepossessions, might perhaps describe the apostle Paul in such dark colours, but even then it is highly improbable. Renan supposes that some Ephesian impostor is meant, a partisan of Nero's, perhaps an agent of the pseudo-Nero, or the pseudo-Nero himself. One thing is pretty clear, that *a polity* is not represented by either of the two beasts in the Apocalypse, or by Paul's man of sin. It is remarkable how long the legend about Nero's revival continued, and how widely diffused it became, though his body was buried publicly at Rome. Not till the 5th century did it become extinct.

The author of John's first epistle has a more general and spiritual conception of antichrist, partly in consequence of the Alexandrian philosophy which had leavened thought in Asia Minor, as is perceptible in the fourth gospel. He finds antichrist *within* the church in any false teacher who corrupts the true doctrine respecting the Father and the Son through a tendency idealising away the practical basis of Christology. Such development of the idea agrees better with the general representation in the discourses of Jesus than the restricted individualising it received from Paul and John *outside* Christianity, though the latter bears the older and Judaic stamp. The author of I. John writes: "As ye have heard that antichrist shall come, even now are there many antichrists. He is antichrist, that denieth the Father and the Son. This is that spirit of antichrist, whereof ye have heard that it should come; and even now already is it in the world" (ii. 18, 22, iv. 3). He that denied the Father and the Son, that did not confess Jesus, was an antichrist in this author's opinion. Probably Gnosticism was in his view more than any other form of error. There was a tendency among the later New Testament writers, as far as we can judge from 2 Peter ii. 15, to find antichrist in erroneous doctrine rather than an individual. False teachers are called followers of Balaam. In the Apocalypse itself certain heretics are termed Nicolaitanes or Balaamites, *i.e.*, destroyers of the people.

The sibylline oracles agree with the Apocalypse in identifying antichrist and Nero. In those of Christian origin belonging to the earliest centuries, we find the current belief that Nero, having fled beyond the Euphrates, should return with an army to perpetrate farther cruelties in Rome. The descriptions in question are based, in part, on those of the apocalyptist, and the tyrant is directly identified with antichrist or Beliar.[3] When the legend about the tyrant's return from the East ceased, the true interpretation both of the fifth head and his mystic number 666 was lost. Irenæus himself did not know the interpretation of 666, and has given several conjectural words more or less suitable to the number.[4] The idea of a personal antichrist was retained by the Christian writers of the 2d and 3d centuries who held the sensuous view of Christ's speedy reappearing to set up his reign on

[1] Düsterdieck in vain disputes this fact, believing that the report in the form in which critics put it into the book, had its source in misunderstood passages of the Apocalypse combined with 2 Thess. ii. 3, &c.

[2] Aurelius Victor is erroneously cited by Renan for his view of the Cæsars. Both in the *De Cæsaribus* and the *Epitome* the narrative begins with Octavius. Julius Cæsar does not appear as emperor.

[3] See book iv. 116, &c., 134, &c.; viii. 140, &c., 70, &c., 152, &c.; and comp. Alexandre's Excursus in vol. ii. of his *Oracula Sibyllina*, 1856. The first vol., containing the poems themselves, with a translation, appeared in 1841.

[4] *Opp.*, *ed. Stieren*, vol. i. p. 801

earth for a thousand years. The figure of this great adversary in connection with the millennial reign was important for such interpreters. The Alexandrian school, however, whose method of interpretation was less literal and gross, generalised the idea in the manner of him who wrote St John's first epistle, making the principle of error or departure from the faith to be personified in antichrist. The great opponent of Christ is an abstraction, a sceptical tendency or principle, not an historical person.

The later Jews had also their antichrist or anti-Messiah, whom they furnished with peculiar attributes, and termed Armillus, ארמילוס. The name appears already in the *Turgum* of Jonathan on Isaiah xi. 4, where the godless Armillus is said to be slain with the breath of Messiah's mouth. In their description he becomes a terrible giant, golden haired, twelve ells in height, as many in breadth, having the width of a span between his deep red eyes. Born in Rome, he will assume to be the Messiah, and obtain many adherents. The first Messiah, Joseph's son, will make war upon him, but be overcome and slain at Jerusalem. After this the second Messiah, David's son, will defeat Armillus with the breath of his mouth, and then God will reassemble the dispersed of Israel, forming them into a united people, Christians and unbelievers being destroyed.[1]

In the apocryphal *Ascension of Isaiah*, published by Laurence, a Jewish-Christian production written in Greek not earlier than the 3d century, the angel Berial, prince of this world, identical with Sammael or Satan, and representing antichrist, is said to descend in the last days, in the form of an impious monarch (Nero), the murderer of his mother. The world will believe in him, and sacrifice to him; his prodigies will be displayed in every city and country, and his image set up. After exercising dominion for three years seven months and twenty-seven days, the Lord will come with His angels and drag him down into Gehenna. The writer's description is evidently moulded on that of the apocalyptist.[2]

Nor is antichrist unknown to Mohammedan theology, in which he is called al Masîh al Dajjâl, the false or lying Christ, or simply al Dajjâl. He is to be one-eyed, and marked on the forehead with the letters C. F. R., *i.e.*, Cafir, or infidel. Appearing first between Irak and Syria, or, according to others, in Khorasan, he will ride on an ass, followed by 70,000 Jews of Ispahan, and continue on earth forty days, of which one will be equal in length to a year, another to a month, another to a week, and the rest will be common days; he is to lay waste all places except Mecca, or Medina, which are guarded by angels; but at length he will be slain by Jesus at the gate of Lud, near Joppa, assisted by the Imam Mahedi, after which the Moslem religion will coalesce with the Christian into one.[3] There is a saying that Mohammed foretold several antichrists, as many as thirty, but one of greater note than the rest.

During the Middle Ages, and those which immediately followed, current opinion discovered antichrist in heretics and sects. The Apocalypse and second epistle to the Thessalonians were supposed to point at false doctrine and its leading representatives. In their zeal against such as did not belong to the same church as their own, ecclesiastics mistook the sense of the passages relating to the dreaded adversary of Christ. Thus Innocent III. (1215) declared the Saracens to be antichrist, and Mohammed the false prophet; and Gregory IX. (1234) pronounced the emperor Frederick II. to be the beast that rose up out of the sea with names of blasphemy on his head (Rev. xiii. 1–6).

As the corruption of the Romish Church increased, and the necessity of reform became more apparent, anti-ecclesiastical thought found antichrist in the Papacy; and that again naturally provoked the church to characterise all heretics as the collective antichrist. The strong language of the apostles became a polemic weapon, easily wielded against any adversary possessing worldly power inimical to the church's interests, or holding opinions incompatible with traditional orthodoxy. The Church of Rome led the way in misapplying the Apocalypse during her contest with civil powers and heretics; her opponents followed the example in turning the instrument against herself. Antichristianism could be embodied in the Papacy as well as in Protestantism. It might be in a corrupt church as well as in heretical doctrine outside it. Accordingly, the Waldenses, Wicliffe, Huss, and many others, found antichrist in the Pope. Luther hurled a powerful philippic *adversus execrabilem bullam antichristi;* and the articles of Schmalkald embody the same view, affirming: "Der Pabst aber, der allen die Seligkeit abspricht welche ihm nicht gehorchen wollen, ist der rechte antichrist."

The history of opinion respecting antichrist, or rather the interpretation of such Scriptures as present the idea, is by no means instructive. Conjectures too often supply the place of sound exegesis. Much error has arisen from mixing up portions of Daniel's vision with those of the Apocalypse, because they refer to different subjects. The apostle borrows characteristic features from Daniel's Antiochus Epiphanes to fill out his picture of Nero. The combination of St Paul's man of sin with St John's antichristian Nero has also led to misapprehension. The idea is variously developed according to the mental peculiarities and knowledge of those who entertained it. Vague and general at first, it was afterwards narrowed, somewhat in the manner of the Messianic one. Its different forms show that it was no article of faith, no dogma connected with salvation. Less definite in the second epistle to the Thessalonians, it is tolerably specific in the Revelation. The author of John's first epistle gave it a spiritual width, consistently with the pantheistic direction which he follows with feeble footsteps. In each case, however, the writers moved within their own times, their knowledge bounded by the necessary limits of the human intellect, so that their subjective views can hardly be accepted as the emanations of minds projecting themselves into the world's outer history with full intelligence of its details. Limited to the horizon of their age, they did not penetrate into the future with infallible certainty. What they express about antichrist is their development of an idea which sprang out of Jewish soil and does not harmonise well with the gradual progress of Christ's spiritual kingdom. It is not unusual, however, for men living in times of peculiar commotion, when the good are oppressed and vice triumphs, to embody rampant opposition to truth and righteousness in a person who concentrates in himself the essence of antichristian hate. If Christ is to conquer gloriously, a mighty adversary is given Him who must be finally and for ever overthrown. Then commences the universal reign of peace and purity under the benign sceptre of the Victor. Over against Christ as King is set a formidable foe, not an abstract principle,—the latter being an incongruous or less worthy adversary in the view of many. Yet it is the very individualising of the antichrist idea which removes it from the sphere of actual realisation. The extension, indeed, of the divine kingdom will encounter opposition; and the reaction of the

[1] See Eisenmenger's *Entdecktes Judenthum*, ii. p. 704, &c.; and Buxtorf's *Lexicon Chaldaicum*, s.v. ארמילוס.

[2] See Laurence's *Ascensio Isaiæ Vatis*, &c., pp. 108, 109, and general remarks, p. 157.

world may appear, if not become, stronger as that extension is more decided; but the personality and intenseness which the apostles impart to the reaction transfer it to the region of the improbable. Humanity is not so vicious as to break away from God with the extreme insanity which the feelings of the sacred writers conjure up in times of fear for the church. (Comp. Gesenius's article "Antichrist" in Ersch and Gruber; De Wette's *Kurze Erklärung of the Second Epistle to the Thessalonians and the Revelation;* Lücke's *Versuch einer vollständigen Einleitung in die Offenbarung des Johannes*, zweite Auflage; Bleek's *Vorlesungen ueber die Apokalypse;* Ewald's *Commentarius in Apocalypsin Johannis*, and his *Die Johanneischen Schriften uebersetzt und erklärt;* Lünemann, *Ueber die Briefe an die Thessalonicher* in Meyer's *Kommentar ueber das Neue Testament;* Davidson's *Introduction to the Study of the New Testament*, vol. i.; Renan's *L'Antechrist;* Jowett's *Epistles of St Paul to the Thessalonians*, &c., vol. i.) (S. D.)

ANTICLIMAX (ἀντι and κλῖμαξ), in rhetoric, is an abrupt declension on the part of a speaker or writer from the dignity of idea which he has attained, as in the following well-known distich:—

> "The great Dalhousie, he, the god of war,
> *Lieutenant-colonel to the earl of Mar.*"

From its character it is plain that it can be intentionally employed only for a jocular or satiric purpose. It frequently partakes of the nature of antithesis, as—

> "Die and endow a *college* or a *cat.*"

From *bathos* it is distinguished by being much more decidedly a relative term. A whole speech may never rise above the level of bathos; but a climax of greater or less elevation is the necessary antecedent of an anticlimax.

ANTICOSTI, a barren island of British North America, situated in the Gulf of St Lawrence, between lat. 49° and 50° N., and between long. 61° 40′ and 64° 30′ W., with a length of 135 miles, and a maximum breadth of 40. Most of the coast is dangerous, but lighthouses have been built at different points, and there are also provision posts for shipwrecked sailors. The lighthouse keepers and other officials are the only inhabitants of the island.

ANTICYRA, in *Ancient Geography*, the name of three cities of Greece. (1.) In Phocis, on the Bay of Anticyra, in the Corinthian Gulf. Its modern name is Aspra Spitia, where some remains are still visible. It was a town of considerable importance in ancient times; was destroyed by Philip of Macedon; recovered its prosperity; and was captured by Flaminius in 198 B.C. (2.) In Thessaly, on the right bank of the River Sperchius, near its mouth. (3.) In Locris, on the left side of the entrance to the Corinthian Gulf, and not far from Naupactus. All three places are said to have been known for their hellebore; but the first was the source of the chief supply. The city was resorted to by those suffering from mental derangement, that they might the more easily obtain the curative herb; and this circumstance gave rise to a number of proverbial expressions, like Αντικίρρας σε δεῖ, or *naviget Anticyram*, and to frequent allusions in the Greek and Latin writers (Suetonius, *Cal.* 29; Persius, *Sat.* iv. 16; Juv. *Sat.* xiii. 97). Hellebore was likewise considered beneficial in cases of gout and epilepsy.

ANTIETAM, a small river of the United States, which rises in Pennsylvania, and flowing into Maryland, joins the Potomac about 50 miles from Washington. An indecisive battle between the Federals under M'Clellan and the Confederates under Lee was fought on its banks on 16th and 17th September 1862. The victory, however, practically lay with the Federals, as the Confederates retreated out of Maryland on the night of the 18th September.

ANTIGONE, the daughter of Œdipus, known in Greek legend, first, for the faithfulness with which she attended her father when he, on discovering that Jocaste, the mother of his children, was also his own mother, put his eyes out and resigned the throne of Thebes; secondly, for having, in defiance of a decree, buried with due rites the body of her brother Polynices, for which act she was sentenced to be buried alive in a vault. Her character and these incidents of her life presented an attractive subject to the Greek tragic poets, especially Sophocles, whose plays of *Antigone* and *Œdipus at Colonus* still exist; and Euripides, whose *Antigone*, though now lost, is partly known from extracts incidentally preserved in later writers, and from passages in his play of the *Phœnissæ*. In the order of the events, at least, Sophocles departed from the original legend, according to which the cremation of Polynices took place while Œdipus was yet in Thebes, not after he had died at Colonus. Possibly his having left Thebes at all is an invention of the poet. Again, in assigning Antigone the tragic end of being buried alive, Sophocles differs from Euripides, in whose play that calamity was averted by the intercession of Bacchus, and was followed by the marriage of Antigone and Hæmon, the son of her persecutor Creon, who had succeeded to the throne. In another version of the legend (Hyginus, *Fab.* 72), founded apparently (Heydemann, *Ueber eine nach Euripideische Antigone*, Berlin, 1868) on a tragedy by some follower of Euripides, Antigone, on being handed over by Creon to her lover Hæmon to be slain, was instead secretly carried off by him, and concealed among herdsmen, where she bore him a son Mæon. The boy having grown up, went to the games at Thebes, and being there recognised by the mark of a dragon on his body, the secret was discovered. Hercules pleaded with Creon in vain for Hæmon, who now slew both Antigone and himself. On a painted vase (engraved by Heydemann, *supra*) appears the scene of the intercession of Hercules. Antigone placing the body of Polynices on the funeral pile occurs on a sarcophagus in the villa Pamfili in Rome, and in the description of an ancient painting by Philostratus (*Imag.* ii. 29), in which it is stated that the flames consuming the two brothers burnt apart, as indicative of their hostility in life.

ANTIGONE (2), in Greek legend, the daughter of Eurytion, king of Phthia, who gave her in marriage to Peleus, the issue being a daughter, Polydora. Peleus having accidentally killed Eurytion in a hunt, some say the hunt of the Calydonian boar, fled and obtained expiation from Acastus, whose wife in malice, because her affection for Peleus was not returned, informed Antigone that it was, upon which Antigone took her own life.

ANTIGONUS I., called *Cyclops*, from his having lost an eye, one of the generals of Alexander the Great, was the son of Philip of Elymiotis. In the division of the provinces after Alexander's death, 323 B.C., Pamphylia, Lycia, and Phrygia Major fell to his share. But Perdiccas, having an eye to universal dominion, determined to divest him of his government, and laid plans for his life, by bringing various accusations against him. Antigonus escaped with his son Demetrius into Greece, where he obtained the favour and protection of Antipater, 321 B.C.; and when soon after, on the death of Perdiccas, a new division took place, he had the province of Susiana added to his former share. He was likewise intrusted with the command of the war against Eumenes, who had joined Perdiccas against the coalition of Antipater, Antigonus, and the other generals. Eumenes was thoroughly defeated, and was obliged to retire with only 600 men to the inaccessible castle of Nora, and a new army that was marching to his relief was also routed by Antigonus. In the interval Antipater had died (318 B.C.), and the opportunity excited the ambition of Antigonus to possess the whole of

Alexander's empire. Polysperchon succeeding Antipater in the regency, to the exclusion of Cassander his son, Antigonus resolved to set himself up as lord of all Asia. On account of the great power of Eumenes, he greatly desired to gain him over to his interest; but that faithful commander, effecting his escape from Nora, raised an army, and was appointed the royal general in Asia. He defeated Antigonus in several engagements, but was at last delivered up to him through treachery, and put to death. Upon this the governor of Upper Asia yielded to Antigonus. The latter now seized upon all the treasures at Susa, and directed his march towards Babylon, of which Seleucus was governor. Seleucus fled to Ptolemy, and entered into a league with him, together with Lysimachus and Cassander, in order to check the exorbitant power of Antigonus (315 B.C.) Notwithstanding this Antigonus made a successful attempt upon Syria and Phœnicia, though these provinces were soon after recovered by Ptolemy, who defeated his son Demetrius, while he himself was employed against Cassander in Asia Minor. They were again taken by Antigonus, who, flushed with success, sent an expedition against the Nabathæan Arabs dwelling in the deserts adjacent to Judæa. In the first enterprise his troops were cut to pieces by the Arabs; but his son commanded the second, and was more successful. Demetrius then expelled Seleucus from Babylon; and, success attending his arms wherever he went, the confederates had to make a treaty with Antigonus, stipulating that he should remain in possession of all Asia, but that the Greek cities should retain their liberty. This agreement was soon violated, under the pretence that garrisons had been placed in some of these cities by Antigonus. At first Ptolemy made a successful descent into Asia Minor, and on several of the islands of the Archipelago; but he was at length totally defeated by Demetrius, in a naval engagement off Salamis, in the island of Cyprus. On gaining this victory Antigonus assumed the title of king, and bestowed the same upon his son; and from that time (306 B.C.) his reign in Asia, and that of Ptolemy in Egypt, and of the other generals of Alexander in their respective provinces, properly commence. Antigonus now prepared a large army, and a formidable fleet, the command of which he gave to Demetrius, and hastened to attack Ptolemy in his own dominions. His invasion of Egypt, however, proved a failure; a battle with Ptolemy at Mount Casius gained Antigonus no advantage, and, after a few other fruitless efforts, he was obliged to retire (306 B.C.) Demetrius attempted the reduction of Rhodes; but, meeting with obstinate resistance, he was obliged to make a treaty upon the best terms that he could, in order to join his father in crushing a confederacy that had been formed between Cassander, Seleucus, and Lysimachus. Father and son advanced with their united forces into Phrygia, and met the enemy at Ipsus. A decisive battle was fought, in which Antigonus fell, in the 81st year of his age, 301 B.C., and with him fell the fortunes of his house.

ANTIGONUS (GONATAS), son of Demetrius Poliorcetes, and grandson of the former Antigonus, was born at Gouni in Thessaly about 319 B.C. On the death of his father in Asia, 283 B.C., he assumed the title of king of Macedonia, but did not obtain possession of the throne till 277, after it had been successively in the hands of Pyrrhus, Lysimachus, Seleucus, and Ptolemy Ceraunus. Antigonus repelled the invasion of the Gauls, and continued in undisputed possession of Macedonia till 273, when Pyrrhus returned from Italy and dethroned him. Pyrrhus fell, 272 B.C., at Argos, and Antigonus was again restored to power. The latter part of his reign was comparatively peaceful, and he gained the affection of his subjects by his mildness of disposition and his cultivation of the arts. He resisted the formation of the Achæan league, but did not resort to arms to enforce his opposition. He died, leaving his kingdom in peace, in the 80th year of his age, and the 44th of his reign, 239 B.C.

ANTIGUA, one of the West Indian Islands, in the British Leeward group, situated 50 miles E. of St Christopher, in lat. 17° 6′ N., and long. 61° 45′ W.; with an area of 108 square miles, and a circumference of about 50 miles. There is often a great scarcity of water in the island, which has also suffered severely from hurricanes; but it is on the whole healthy and its soil is very fertile, producing large quantities of sugar, and usually enough of grain for home consumption, as well as some cotton and tobacco. Its high and rocky coast is much indented by bays and arms of the sea, several of which form excellent harbours; that of St John's, the capital, is safe and commodious, but is much inferior to English Harbour, which is capable of receiving vessels of the largest size. Goods to the value of £234,011, and including sugar, molasses, rum, and cotton, were exported in 1870, being an increase of £33,038 as compared with 1869; the value of the imports, on the other hand, had increased during the same period from £174,357 to £164,178. In 1870, 422 ships of 25,228 tons entered, and 425 of 24,977 tons cleared the ports of the island. The government of Antigua is vested in a governor and executive and legislative councils, while four of the ten elective members of the general legislative council of the Leeward Islands, are chosen from, and by, the legislative council of Antigua, in addition to one non-elective member nominated from the same body by the Queen. In 1870 the revenue amounted to £41,136, the expenditure to £31,315, and the public debt to £52,195. The chief source of revenue is the import duty, which amounted to about £20,000 in the same year. Antigua was discovered in 1493 by Columbus, who is said to have named it after a church in Seville, called Santa Maria la Antigua. It however remained uninhabited until 1632, when a body of English settlers took possession of it, and in 1663 another settlement of the same nation was effected under the direction of Lord Willoughby, to whom the entire island was granted by Charles II. It was ravaged by the French in 1666, but was soon after reconquered by the British, and was formally restored to them by the treaty of Breda. Since then it has been a British possession. Population in 1871, 35,157.

ANTILEGOMENA (ἀντιλεγόμενα, contradicted or disputed), an epithet applied by the early Christian writers to denote those books of the New Testament which, although sometimes publicly read in the churches, were not for a considerable time admitted to be genuine, or received into the canon of Scripture. These books are so denominated in contradistinction to the *Homologoumena*, or universally acknowledged writings. The following is a catalogue of the *Antilegomena:—the Epistle to the Hebrews, the Epistle of St James, the Second Epistle of St Peter, the Second and Third Epistles of St John, the Epistle of St Jude, the Apocalypse, or Revelation of St John.* The earliest notice which we have of this distinction is contained in the *Ecclesiastical History* of Eusebius (iii. 25), who flourished A.D. 270–340; but the meaning of the passage is by no means clear, and it has accordingly given rise to considerable controversy.

ANTILLES, a name that is usually, although by no means uniformly, applied to the whole of the West Indian Islands, with the exception of the Bahamas; it has also, on the one hand, been employed to designate smaller portions of the same group, and, on the other, it has been extended so as to comprehend the whole archipelago, inclusive of the Bahamas. The traditional derivation of the word Antilles itself from Antilla, a continent supposed to lie to the west of the Azores, and for which Cuba, or some other West Indian island, was mistaken, is too doubtful and too vague in its application to be of any value in determining the proper use of the term; the weight of authority seems to be in favour of the first acceptation. In this sense the Antilles have been divided into two groups:—the Greater Antilles, including Cuba, Jamaica, Hayti, and Porto Rico; and the Lesser Antilles, forming the remainder of the islands. See WEST INDIES.

ANTIMACHUS, the Colophonian, a Greek poet who was honoured by the Alexandrine grammarians with the second place in their epic canon. Of his works nothing remains to us but the merest fragments; and of his life, we know little more than that he was born at Claros; was beaten by a rival in a poetical competition at Samos; met, either then or in equally discouraging circumstances, with Plato; fell in love with a lady called Lyde; lost her by death; bewailed her in an elegy of extreme erudition, if not of extraordinary pathos; and celebrated in his epic the seven heroes of Thebes. Schellenberg collected his fragmentary remains at Halle in 1786; and Roll at Dillenberg, in 1845. H. G. Stoll published at Göttingen in 1841 *Animadversiones in Antimachi Fragmenta;* and the remains of the *Thebais* are to be found in Düntzer, *Fragm. des Episch. Poes. der Griech.*

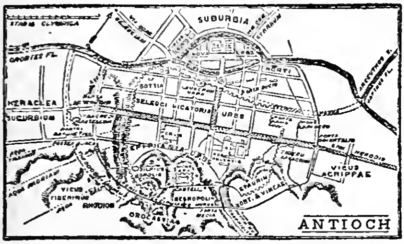
ANTIMONY, a metal found native to a small extent in many of the localities from which its ores are derived. It has been obtained at Sahlberg, near Sahl in Sweden, at Andreasberg in the Harz, at Allemont in Dauphiny, Przibram in Bohemia, besides being brought from Borneo, Chili, Mexico, New Brunswick, &c. It also occurs in nature alloyed with other metals; allemontite being arsenical antimony; dyscrasite, antimonial silver; and breithauptite, a native alloy of antimony and nickel. Among the ores of antimony may be enumerated valentinite, or white antimony, and cervantite, or antimony ochre, both oxides of antimony; and kermesite, red antimony, or antimony blende, an oxysulphide of the metal. Various sulphantimonites of other metals are also met with, but they possess only a mineralogical interest. The antimony of commerce is derived almost entirely from the sulphide, stibnite, or grey antimony ore (Sb_2S_3), which is found in great abundance in Borneo, in Nevada, and at Prince William antimony mine, New Brunswick. It is also mined at Schemnitz and Kremnitz in Hungary, at Przibram in Bohemia, at Wolfsberg in the Harz, and at Braunsdorf, near Freiberg, Bavaria. Formerly it was largely produced in Cornwall, but it is no longer worked on a commercial scale in Great Britain. Stibnite occurs generally in veins, and has a leaden grey colour, with a metallic, sometimes iridescent lustre; it fuses with great facility, and produces a grey streak. It is the *στίμμι* or stibium of the ancients, who applied to it the epithet *πλατυόφθαλμον*, from its having been used by women in Eastern countries to give increased lustre to their eyes, by darkening the eye-lashes, a practice still pursued in some parts. The *paint* said in the Holy Scriptures to have been used by Jezebel, seems to have been this substance; for St Jerome, who knew the manners of Eastern women, has, in the Vulgate, rendered the passage "*oculos ejus posuit stibio.*" Stibnite was the *lupus metallorum* of the alchemists, and Basil Valentin was able to show that it contained sulphur. That famous alchemist was acquainted with metallic antimony, and by him and his successors it was known as *regulus*, or regulus of antimony, from the readiness with which it acted on the royal metal gold. The tradition that the name antimony was given to the sulphide on account of a preparation of it having proved fatal to the monks (hence *anti-monachos*) in a German religious house will hardly bear investigation. Crude antimony of commerce is the ore separated from its associated earthy gangue—an operation effected by simple fusion. The sulphide is then reduced to an oxide by roasting in a reverberatory furnace. From this oxide metallic antimony is obtained by fusion with charcoal, which has been saturated with a solution of carbonate of sodium. The metal may also be prepared direct from the sulphur ore by roasting with a mixture of cream of tartar and nitre, or with iron filings. Antimony is a brilliant silver-grey metal, having a foliated texture and a strong tendency to assume a crystalline structure, which causes the cakes of metal to present a characteristic stellate surface. Its specific gravity is 6·715; it melts at 842° Fahr., and when heated to redness takes fire, burning with a brilliant white flame. It is brittle, and can be easily pulverised. Antimony is chiefly valuable for the alloys it yields with other metals. Britannia metal is an alloy largely used, containing usually about 81 parts of tin, 16 of antimony, 2 of copper, and 1 of zinc. Type metal contains varying proportions of lead and antimony, ranging from 17 to 20 per cent. of the latter, or even more, according to the hardness desired; with sometimes small proportions of other metals for stereotype plates, &c. Babbitt's anti-friction metal for the bearings of machinery is composed of 83·3 parts of tin, 8·3 parts of copper, and 8·3 of antimony. Antimony alloys with lead and tin, separately or in combination, are also used in place of gun metal for the bushes of heavy machinery. Antimonial preparations are of great value in pharmacy, and for such purposes it is essential that they should be absolutely free from the arsenical and other impurities which commercial antimony and its ores always contain. The principal preparation used medicinally is tartarated antimony, or tartar emetic, a tartrate of potash and antimony. Taken in small doses, from $\frac{1}{16}$th to $\frac{1}{6}$th of a grain, tartar emetic acts as diaphoretic, renders mucous surfaces moist, and promotes secretion of urine. In larger doses it excites nausea, and, as its name indicates, vomiting. It is also prepared in the form of an ointment for external application as a counter-irritant, producing a painful pustular eruption. Antimonial wine is a preparation of tartar emetic, used as a diaphoretic and expectorant. Butter of antimony, or the liquor of chloride of antimony, is used as a powerful caustic, and antimonial powder, or James's powder, is employed as a diaphoretic in fevers and rheumatism. Other officinal preparations containing antimony are—oxide of antimony; black antimony, or the native sulphide, prepared; sulphurated antimony; and compound calomel pills. Crude antimony sulphide is used in the manufacture of black lead pencils. For the action of antimony as a poison, see POISONS.

ANTINOMIANS (ἀντί, against, and νόμος, law), a term first employed by Luther as a designation of the followers of John Agricola, who maintained that the moral law was not binding, as such, upon Christians (see AGRICOLA, JOHANNES). In this, as in many other cases, however, the thing existed long before the name. From the 1st century of the Christian era downwards, there have been those who, on one ground or other, denied that the law was of use or obligation under the gospel dispensation, and the term Antinomian is, accordingly, applied with sufficient propriety to many who lived at an earlier date than the sect or school to describe whom Luther invented it. It would seem, from several passages in the New Testament (Rom. iii. 8, 31, vi. 1; Eph. v. 6; 2 Pet. ii. 18, 19), in which the apostles warn their followers against perversions of their doctrine as an excuse for licentiousness, that Antinomianism, in its grosser form, found a place even in the primitive church. It is to be noticed that this first manifestation of the heresy seems to have been due to the same cause as that which operated in the case of Agricola,—a mistaken interpretation of the doctrine of justification by faith. The Gnostic sects, several of whom are classed as Antinomian, seem to have proceeded on the principle, that being spiritual their nature could not be corrupted whatever their moral conduct might be. Gnostic Antinomianism seems, therefore, to have been in this respect analogous to that of the High Calvinists, some of whom went so far as to maintain that an elect person did not sin even when he committed actions in themselves wicked. Such were the Antinomians in England during the Protectorate. A doctrine so extreme, and sanctioning so unmistakably an immoral life, is to be carefully distinguished from the Antinomianism combated by Luther, which was a matter of theory not necessarily affecting conduct. It is not easy to apprehend or to state with clearness the precise views of Agricola as to the relation between the Christian and the moral law. His own statements were more than once modified or retracted in the course of discussion, and there can be no doubt that Luther made him responsible for opinions which he did not hold. The exaggeration characteristic of all controversies seems to have prevailed in this case to an unusual extent on both sides, and neither disputant should always be taken literally at his word, whether he speaks for himself or for his opponent. It was probably a desire to establish Luther's negation of the Roman Catholic doctrine of good works on some firm ground of principle, that first led Agricola to insist as he did on the essential incompatibility between the law and the gospel. The law of Moses, he taught, was for the Jews alone, and was not a rule of life to Christians, who might with safety altogether neglect it. On the other hand, he never denied that the Christian was under a moral government with an adequate sanction, which laid him under obligation to lead a holy life. What he maintained was that the New Testament furnished all that was necessary for impulse and guidance in the path of Christian duty, not in the form of positive precepts so much as of principles and motives. Thus explained, the difference between the orthodox and Agricola's party reduces itself within a comparatively narrow compass, though, after the fullest explanation, it remains a real difference and a standing subject of controversy.

ANTINOMY is the word employed by Kant, in the Critical Philosophy, to mark the inevitable conflict or contradiction into which, according to his view, speculative reason falls with itself, when it seeks to conceive the complex of external phenomena, or nature, as a world or cosmos. Literally the word means a conflict or opposition of laws (*Widerstreit der Gesetze*). It is used by Kant both in a generic and in a specific sense; the fate that lies upon the speculative endeavour of human reason taking the form of four special contradictions. For the generic sense Kant also has the word Antithetic, each antinomy being set forth in the shape of thesis and antithesis, with corresponding demonstrations, the perfect validity of which, in all cases, he most positively guarantees. The conflicting propositions, or the cosmological ideas involved in them, are intimately, though somewhat obscurely, related to the four heads of categories of the understanding in the Kantian system, but this is not the place to enter into such details. Expressed in the shortest form, the theses run thus:—The world (1) is limited in space and time, (2) consists of parts that are simple, (3) includes causality through freedom, (4) implies the existence of an absolutely necessary being. To these answer the antitheses:—The world (1) is without limits in space or time, (2) consists of parts always composite, (3) includes no causality but that of natural law, (4) implies the existence of no absolutely necessary being. The theses were taken by Kant from the speculative cosmology of the Wolffian school; the antitheses are the not less dogmatic assertions made or suggested by empirical thinkers. Since, according to Kant, equally valid arguments can be adduced on each side, while, as mutually contradictory in their dogmatic sense, the two sets of propositions cannot both be true, it is plain that reason must have gone beyond its powers in seeking for a speculative knowledge of that which can be given in no experience. But the function of a true philosophy does not stop short with the detection of this internal strife of speculative reason; the strife must be composed, and Kant holds that none but his own critical doctrine is equal to the task. The first two antinomies he overcomes by showing that theses and antitheses, when critically understood of mere phenomena, are both alike false; the others, by showing that the opposed members, when understood, again critically, of noümena and phenomena respectively, may both be true. This amounts to saying, that in neither of the two sets of cases (though in different ways) is the contradiction real, however really it has been intended by the opposing partizans, or must appear to the mind without critical enlightenment. It is wrong, therefore, to impute to Kant, as is often done, the view that human reason is, on ultimate subjects, at war with itself, in the sense of being impelled by equally strong arguments towards alternatives contradictory of each other. Hamilton's Law of the Conditioned—that all positive knowledge lies between two extremes, neither of which we can conceive as possible, but yet, as mutual contradictories, the one or other of which we must recognise as necessary—while suggested by the Kantian doctrine of the Antinomy of Pure Reason, is distinctly at variance with it. In the realm of phenomenal experience, actual or possible, when it is properly conceived, Kant allows of no conflict; and, though he denies that we can have speculative knowledge of a realm transcending experience, he is satisfied of this at least, that knowledge of the one realm may go forward without prejudice to moral conviction of another. (G. C. R.)

ANTINOUS, a beautiful youth, who was page to the emperor Hadrian, and greatly beloved by him. After his mysterious death by drowning in the Nile (130 A.D.) Hadrian—for whose sake, according to one account, he had offered himself a voluntary victim to destiny—caused the most extravagant respect to be paid to his memory by ceremony and monument. Not only were cities called after him, medals struck with his effigy, and statues erected to him in all parts of the empire, but he was raised to the rank of the gods, temples were built for his worship, festivals celebrated in his honour, and oracles delivered in his name. The cities that showed most zeal for the new divinity were Bithynium (Antinoopolis) his birth-place, Besa (Antinoopolis) in Egypt, Mantinea in Arcadia, and Athens. It was in Athens that his greatest festivals were held—the Αντινόεια ἐν ἄστει (in the city) and the Αντινόεια ἐν Ἐλευσῖνι (at Eleusis). A remarkable impulse was given to the art of sculpture by the endeavour to produce an idealised representation of the deified page. We still possess a colossal bust in the Vatican, a bust in the Louvre, a bas-relief from the Villa Albani, a statue in the Capitol, another in Berlin, another in the Lateran, and many more. The medals with his head are equally numerous. (Levezow, *Ueber den Antinous*; O. Müller, *Handbuch der Archäologie*; Müller-Wieseler, *Denkmäler der alten Kunst*.)

ANTIOCH (Ἀντιόχεια), a city in Syria, long. 36° 10′ E., lat. 36° 11′ N., described as "Epidaphnes" (ἡ ἐπὶ Δαφνῃς, or ἐπὶ Δάφνῃ), or as "on the Orontes," to distinguish it from the fifteen other Greek towns which, like itself, owed their foundation to Seleucus Nicator, and their names to his father Antiochus. While the wide-spread notoriety of Daphne, with its beautiful grove, compared to the vale of Tempe, and with its extraordinary excesses of pleasure, rendered it available as a local designation for Antioch, the river Orontes also seems to have served the same purpose with more than usual interest, owing, perhaps, to its fabulous history. Originally it had been called Typhon, from the snake-legged giant of that name (Strabo, p. 750), who here struck by the thunderbolt of Jupiter, and seeking escape under the earth, formed the bed of the river by his trail, and its source by his descent. Orontes, it was said, was the name of a man who had built a bridge over the river, and when in Roman times the course of the stream was partly changed, a tomb (*soros*) was found in the old bed containing the bones of a man of colossal size,



which the oracle declared to be those of Orontes (Pausanias, viii. 29, 3). On the coins of Antioch struck by Tigranes, and frequently on those of later times, the city is personified as a female figure seated on a high rock or hill, from under which issues the Orontes in the form of a youth in the attitude of swimming. The same representation occurs in a marble statue in the Vatican, and in a silver statuette in the British Museum; and in each case there can be little doubt that the original model was the celebrated statue of Antioch by Eutychides, a pupil of Lysippus.

On the dismemberment of the Eastern empire founded by Alexander the Great, it fell to Seleucus to make himself master of that portion of it included in Syria. It was an age remarkable for the building of new towns more or less on the plan of Alexandria, and accordingly Seleucus, instead of establishing himself at Antigonia, the newly-built capital of his defeated rival, chose a site a little further down the Orontes, about 20 miles from its mouth, for the capital of his new kingdom, the task of laying out and building it being entrusted to the architect Xenæus. On Mount Silpius was placed the citadel, and on the slope towards the river the town. Seleucus destroyed Antigonia, transferred its inhabitants to Antioch, and perhaps, as has been said, utilised its building material. In addition to this new population there were the old inhabitants of the village of Iopolis or Ione, which had before occupied the citadel, and which traced its origin to Ione, an Argive fugitive from Egypt, in search of whom Triptolemus had been sent from Eleusis. Though this legend appears to have originated simply from the name Ione, the people of Antioch yet boasted of a common descent with the inhabitants of Attica, struck coins with the head of Pallas and an owl, precisely like coins of Athens, and maintained the traditions of Triptolemus as of a sort of ancestral hero. Besides Iopolis, the villages of Meroe, afterwards a suburb, and Bottia, on the banks of the Orontes, where Alexander dedicated a temple to Jupiter Bottiæus, claimed to have furnished the original inhabitants of Antioch. But the town founded by Seleucus, 300 B.C., soon became insufficient for the influx of population, and a new district had to be enclosed, the original walls being allowed to remain. For the same purpose a third addition was made in the time of Seleucus Callinicus (246–226 B.C.), and a fourth under Antiochus Epiphanes (175–164 B.C.), to whom the city owed also many new buildings of great splendour. From its four parts, each separately walled, Antioch was now called a *tetrapolis*, and in point of situation, architectural magnificence, and resources of enjoyment, ranked after Rome and Alexandria as the next city of its time. The chief retreat of pleasure was the cypress grove of Daphne, at a distance of between 4 and 5 miles, but connected with the city by a suburb called Heraclea, the road passing among beautiful villas, gardens with fountains, hot springs, medicinal wells, brooks, and, in short, if we may trust the ancient writers who speak from personal observation, every combination of salubrity and beauty. Seleucus Nicator had laid out the grove of Daphne, and erected in it a temple of Apollo and Diana, to which deities an annual festival was held in August, attended by all the people of the neighbourhood. Round the temple was an enclosure or asylum within which refugees were safe. In the temple of Apollo was a colossal statue of that god, the work, it was said, of the sculptor Bryaxis, of which, apparently, there is a copy on the coins of Antiochus Epiphanes. While the emperor Julian was at Antioch preparing for the Parthian war, this temple was burned, but whether the fire was due to the antipathy of the Christians, or to accident, was never ascertained. The city itself, abounding in fine buildings, seems to have been for nothing so remarkable in this direction as for its streets and porticoes, which were styled "golden," with reference to the splendour of the columns, and perhaps, more literally, to the application of gold as a means of ornamentation. The principal street traversed the entire length of the city from east to west, a distance of about 4 miles, having four parallel rows of columns, forming a broad road in the middle open to the sky, and at each side a narrower covered way or portico. The road in the middle was laid with granite in the time of Antoninus Pius. From this main street others branched off at intervals up to the higher part of the town on the one hand, and down towards the river on the other. Where such junctures occurred, the porticoes of the main street were carried over in the form of arches. Among the buildings of which particular mention is made, are—(1), a temple to Jupiter Capitolinus, in imitation of the temple to the same deity in Rome, situated probably on Mount Silpius; (2), the theatre, begun by the Seleucidæ kings, enlarged by Agrippa and Tiberius, and finished by Trajan; and (3), the great Christian church begun by Constantine and completed by Constantius, which stood until 526 A.D., when it was destroyed by an earthquake and fire. Its dome-shaped roof is said to have been of immense height, while many parts of the building glistened with precious stones and ornaments of gold. The altar within it faced the west. From the description it is thought to have resembled St Vitalis at Ravenna. The necropolis appears to have been situated on Mount Casius, above Antioch, where are still sepulchres cut in the rock, afterwards used as cells by anchorites, among them Zeno, who died about 420 A.D. With a plentiful supply of water for private purposes from the wells and fountains in the city, it was yet necessary to maintain the public baths, which in Roman times became numerous, by aqueducts conveying water for some distance. The ruins of one of these aqueducts still remain, admired for the solidity of the masonry and the colossal scale of the structure (see AQUEDUCT). But with all its charms Antioch was beset by a danger which, often threatening, several times succeeded in laying its fairest aspect waste. The first recorded earthquake occurred 148 B.C., but the myths of the giants Pagres and Typhon there struck by the thunderbolts of Jupiter seem to refer to similar commotions at a remoter period. A second earthquake, 37 A.D., in the reign of Caius Cæsar, caused so much damage that the emperor sent two senators to look to the affairs of the city. A third followed in the time of Claudius. One effect of these disturbances was to increase the tendency to superstition, of which there was an instance in the magician Dabbonius, who placed a bust on a purple column in the centre of the city, and inscribed it ἀσειστα ἄπτωτα, but in vain, for the next earthquake cast it down. Much more severe was the earthquake 115 A.D., while the city was full of the Roman army which Trajan was to lead against the Parthians. The rivers changed their courses, Mount Casius shook, and it was only by taking shelter for several days in the circus that Trajan himself escaped danger from the falling buildings. The city being restored partly by the aid of Trajan and Hadrian, was spared any serious calamity of this kind till 526 A.D. when it was entirely destroyed, the loss of life, all the greater because of an assembly of Christians then met, being reckoned at 250,000 persons. There had before been two shocks, 341 and 457–8 A.D., the latter attended with considerable loss. Again, on Nov. 29, 528 A.D., occurred another earthquake, through which 5000 lives were lost. There appears to have been a violent shock, 587 A.D., followed on the last day of October 588 by another, attended with a terrible destruction of life. But the people of Antioch were not without troubles of their own making, as when, by their disaffection towards the king Demetrius, they caused him to seek the aid of a body of Jews, with whom he fell upon his subjects, slaying a vast number, and setting fire to the city. In 83 B.C. Tigranes, either by invitation or by force, took Antioch, but was compelled to leave it by Lucullus, who placed on the throne Antiochus Philopator. Syria became a Roman province in the time of Pompey, who (64 A.D.) enlarged the temple at Daphne, and conceded to Antioch autonomy. In 47 A.D. Cæsar visited Antioch on his expedition from Alexandria against Pharnaces, and was regarded as a benefactor, and styled dictator, because he allowed the town to retain its freedom, and added several public works of importance. Augustus was no less favourably inclined to the famous Eastern city, which on the news of the defeat of Antony at Actium, hastened to espouse the cause of the emperor, and even instituted an era from the day of that battle, which, however, was not long retained. The usual era from which reckonings were made in Antioch, and over a great part of the East, down to the 10th century, was 312 B.C., in which year Seleucus took Babylon. It was known as the era of the Seleucidæ. Successive emperors showed their favour for the city by visits or the erection of public works. Germanicus died at Antioch 19 A.D.; his body was burned in the forum, and a monument erected over his ashes. Titus, it is said by Malala, placed the cherubim which he removed from Jerusalem on one of the gates of Antioch, and there seems to be confirmation of this statement in the fact, that one of the gates continued long to be named after these figures. Hadrian built an aqueduct for the town with a reservoir (*castellum*) at Daphne, in the form of a temple to the nymphs and naiads. Under Commodus a new splendour was given to Antioch by the celebration of the Olympic games at Daphne. Buildings were erected for the practice of athletic feats generally, and in particular for the use of those who competed in the games. In 266 A.D. the Persians invaded Antioch, appearing suddenly on the hills while the people were assembled in the theatre, where many were slain by the enemy's arrows before escape was possible. The Christian church, partly built by Constantine, and finished by his son, has already been mentioned, and from its great size it may be assumed that the Christian population of Antioch was already considerable. In the time of Theodosius the entire population is given by Chrysostom at 200,000, of which number about the half were orthodox Christians,—a name which was here first applied to the disciples of Christ (Acts xi. 26). From 252 to 380 A.D. ten assemblies of the church were held at Antioch. It had been the residence of the apostle Peter, as it was afterwards that of the Patriarch of Asia. But in the history of Christianity at Antioch no period is so memorable as the reign of the emperor Julian, whose measures directed against the new religion—such as closing the church and allowing the temple of the Jews to be restored—brought upon himself an amount of odium which was far from being counterbalanced by success in his efforts to revive the old rites of Apollo and Jupiter. Valens, though not orthodox, was yet liberal in the erection of new buildings in Antioch,—among them a forum surrounded by four basilicas, and with a high column in the centre surmounted by a statue of Valentinianus. This he did after having made peace with the Persians, Nov. 10, 371 A.D. The reign of Theodosius the Great was signalised by a fierce sedition in Antioch, caused by a tax which he had imposed in 387 or 388 A.D., a year of famine. The statues of the emperor and the imperial family were thrown down, and a tumult raised which was suppressed with difficulty. Many of the offenders were punished with great severity, while the town itself was deprived of its privileges as a metropolis. In the time of Leon a temple was erected in Antioch to Simeon Stylites, whose body was conveyed to the city from the hill, between 30 and 40 miles to the east, where, on the top of a column 40 or 60 feet high, he had lived in self-imposed martyrdom for thirty years. Under Zeno great efforts were made to restore the city to its original splendour before the earthquakes of 526 and 528 A.D. Its name was now changed to Theopolis, but the change was of short duration, as were also the new buildings; for in 538 A.D. Chosroes, the king of Persia, took the town, and, after removing all the plunder, even that of the church, gave it over to his soldiers, by whom the greater part of it was set on fire. It was again partly revived by Justinian, but from this time gradually sank from its high position of queen of the East. Under Heraclius (635 A.D.) it fell into the hands of the Saracens, who held it till 969 A.D., when it was restored to the Roman dominion by Michael Burza and Peter the Eunuch, and so retained till 1084 A.D., when it fell into the power of the Turks, from whom again it was captured by the Crusaders, 1098 A.D. In 1268 A.D. it was taken by the sultan of Egypt, and never revived from the destruction which it then suffered. Of the ancient city little now remains except a great aqueduct bridge and part of the massive walls, which are still to be seen scaling step by step the precipitous hills. At one place the wall is carried over a deep ravine with an arch about 60 feet high. Across the Orontes is a bridge of nine arches, with two towers having gates plated with iron, whence the bridge is known as the iron bridge. Neither the harbour nor the ancient walls which divided the four parts of the city can now be traced. As in the case of many other Greek cities in Asia, once famous for their beauty, the site of Antioch is now studded with squalid hovels of mud and straw. The people live by the produce of the mulberry trees and by growing tobacco, which is of a fine quality. It is still called (Antioch) Antakie, and is sometimes, as in 1822, reminded of its ancient calamities arising from earthquakes. In 1835 it contained 5600 inhabitants, with 6000 Egyptian soldiers under Ibrahim Pasha, who had then his headquarters there. (C. O. Müller, *Antiquitates Antiochenæ*, Göttingen, 1839, from which the plan of Antioch has been here adapted; Bishop Pococke, *Description of the East*, Lond. 1743–5; Taylor, *La Syrie, la Palestine, et la Judée*, Paris, 1855; and *Voyage Pittoresque de Syrie.*) The ancient writers, from whom most of our information concerning Antioch is derived, are—(1) Malala (Johannes), Antiochenus, *Historia Chronica*, Oxon., 1691; (2) Libanius, the Sophist, who had a school in Antioch in the time of the emperor Julian; and, (3) Chrysostom (John), patriarch of Constantinople. (A. S. M.)

ANTIOCH IN PISIDIA, another of the many cities founded by Seleucus Nicator, was situated on the south side of the range of mountains between Phrygia and Pisidia Its remains, which were identified by Arundel in 1833, are close to the modern Yalobatch, in lat. 38° 18′ N., and long. 31° 23′ E., and include the ruins of several temples, a theatre, and a magnificent aqueduct. It was against the Jewish inhabitants of this Antioch that Paul and Barnabas "shook off the dust of their feet" (Acts xiii. 51).

ANTIOCHUS I. (SOTER, the Deliverer) succeeded his father Seleucus Nicator, the founder of the Syrian kingdom, in 280 B.C. He maintained for a time his father's Macedonian policy, but at length came to terms with Antigonus Gonatas. Successful at first against the Gauls, who had invaded Asia Minor, he was finally slain by them in battle (261 B.C.)

ANTIOCHUS II. (THEOS, the God), the son and successor of Antiochus I. Under him Syria was troubled with a long Egyptian war, and lost Parthia and Bactria, which became independent. He was forced by Ptolemy of Egypt to put away his wife and marry an Egyptian princess, Berenice; but on Ptolemy's death Berenice was discarded, and Laodice restored. The latter, however, out of revenge or mistrust, procured the death of her husband, her rival, and their son, 246 B.C.

ANTIOCHUS III., surnamed the Great, was the son of Seleucus Callinicus, and ascended the Syrian throne at the age of fifteen, on the death of his brother, Seleucus Ceraunus. His reign embraced a series of wars against revolted provinces and neighbouring kingdoms, in the prosecution of which his disasters and successes were equally great. His march to India; his agreement with Philip of Macedonia for the partition of Egypt; his conquest of Palestine and Cœle-Syria; his occupation of Asia Minor and the Thracian Chersonese; his collision with the Romans; his expedition into Greece, with the defeat at Thermopylæ by Acilius Glabrio, and at Mount Sipylus (in Asia Minor) by Scipio; and his dearly purchased peace in 188 B.C., are the chief events of his life. He was killed in an attempt to plunder a temple at Elymais, 187 B.C., and was succeeded by his son Seleucus Philopator.

ANTIOCHUS IV. (EPIPHANES, the Illustrious, and by parody, EPIMANES, the Insane), who had been a hostage in Rome from 187 B.C., ascended the Syrian throne on the death of Seleucus, 175 B.C., and soon made himself famous by his conquest of Cœle-Syria, Palestine, and Egypt itself, with the exception of Alexandria, which would likely have also been his if the Romans had not interfered and forbidden him the country. During his Egyptian campaigns he twice took Jerusalem (170 and 168 B.C.); but he appears to have seen that he could never hope to subdue Judæa until he had rooted out the peculiar Jewish religion. He accordingly promulgated a decree, enjoining uniformity of worship throughout his dominions; and, on the refusal of the Jews to obey it, he went in person to Jerusalem and endeavoured to force on them the worship of the Greek deities. This persecuting policy stirred up the successful resistance of the Maccabees; and it was while hastening to quell this revolt that he fell ill of a loathsome disease, and died, raving mad, at Tabæ, in Persia, 164 B.C. His death was thought by the Jews to be an appropriate punishment for his persecution of them.

ANTIOCHUS VIII., king of Syria, was the second son of Demetrius Nicator. During his reign (125–96 B.C.) those discords and wars began between the princes of the royal house of Syria, which form almost its sole history, till the kingdom was reduced to a Roman colony in 65 B.C.

ANTIOCHUS, OF ASCALON, a philosopher of the 1st century before Christ, who, coming under the influence of Philo the Academic and of Mnesarchus the Stoic, was led to attempt a reconciliation between their antagonistic doctrines, and thus gave rise to what has been called the Fifth Academy In regard to the great question of the degree of certainty attainable by man, he held, in opposition to the scepticism of Philo, that the human intellect has in itself a sufficient test of truth; and in regard to the question wherein happiness consists, he maintained that, while virtue was the greatest essential, the circumstances of life were not a matter of indifference. Of his writings none have been preserved to us; and for the greater part of our information we are indebted to Cicero, who had studied under him at Athens, and continued to keep up a friendly intercourse with him afterwards. He visited Alexandria and Rome, and lectured on philosophy in both cities.

ANTIOPE (1), in Greek legend, the mother of Amphion and Zethus, was, according to the *Odyssey* (xi. 260), a daughter of the river god Asopus. In later poems, as in the *Cypria*, she is described as the daughter of Lycurgus, who appears as a king of Thebes. Her beauty attracted Jupiter, who, assuming the form of a satyr, took her by force. After this she was carried off by Epopeus, king of Sicyon, who would not yield his possession of her till compelled by her uncle Lycus. On the way home she gave birth, in the neighbourhood of Eleutheræ, to the twins Amphion and Zethus, of whom the former, some supposed, was the son of the god, the other the son of Epopeus. Both were left to be brought up by herdsmen. At Thebes Antiope now suffered from the persecution of Dirce, the wife of Lycus, but at last escaped towards Eleutheræ, and there found shelter, unknowingly, in the house where her two sons were living as herdsmen. Here she was discovered by Dirce, who ordered the two young men to tie her to the horns of a wild bull. They were about to obey, when the old herdsman, who had brought them up, revealed his secret, and they now carried out the punishment on Dirce instead. For this, it is said, Bacchus, to whose worship Dirce had been devoted, visited Antiope with madness, which caused her to wander restlessly all over Greece till she was cured, and thereafter married by Phocus of Tithorea, on Mount Parnassus, where at last both were buried. Their tomb is mentioned by Pausanias, ix. 17, 4, x. 32, 7.

ANTIOPE (2), an Amazon who bore to Theseus a son, Hippolytus. As to how Theseus became possessed of her there are various reports. Either she gave herself up to him out of love, when with Hercules he captured Themiscyra, the seat of the Amazons, or she fell to his lot then as a captive. Or again, Theseus himself invaded the dominion of the Amazons and carried her off, the consequence of which was a counter-invasion of Attica by the Amazons. After four months of war peace was made, and Antiope left with Theseus as a peace-offering. In another account she had joined the Amazons against him because he had been untrue to her in desiring to marry Phædra. Antiope is said to have been killed by another Amazon, Molpadia, a rival in her affection for Theseus. Elsewhere it was believed that he had himself killed her, and fulfilled an oracle to that effect.

ANTIPAROS, the ancient *Oliaros*, an island of the kingdom of Greece, one of the Cyclades, in the modern eparchy of Naxos, situated on the west of Paros, from which it is separated by a strait about a mile and a half wide at the narrowest point. It is 7 miles long by 3 broad, and contains about 500 inhabitants, most of whom are collected in Kastro, a village on the north coast; their chief employments are agriculture and fishing. The only remarkable feature in the island is a stalactite cavern, which is situated near the south coast, and is reached by a narrow passage, that is broken by several steep and somewhat dangerous descents. The grotto itself, which is supposed to be about 80 feet high, and more than 300 in length and breadth, presents a scene of the most dazzling brilliance and splendour. M. de Nointel discovered it in 1673, but there is reason to believe that it had been known to the ancients.

ANTIPAS, Herod. See Herod Antipas.

ANTIPATER, regent of Macedonia during Alexander's Eastern expedition, 334 B.C. He gained this distinguished position by his faithful attachment and his prudence. In 330 he had to subdue the rebellious tribes of Thrace; but even before this insurrection was quelled, the Spartan king Agis had risen against Macedonia. Having settled affairs in Thrace as well as he could, Antipater hastened to the south, and in a battle near Megalopolis, gained a complete victory over the insurgents. His regency was greatly molested by the arrogance and ambition of Olympias, the mother of Alexander. The repeated complaints which both parties sent to Alexander induced the latter to invite Antipater to Asia, and to appoint Craterus regent in his instead. But before this could be effected, Alexander died at Babylon. In the first partition of the empire among the Macedonian generals, Antipater and Craterus had allotted to them the administration of the dominions in Europe with the exception of Thrace, which was given to Lysimachus. The death of Alexander tempted the Greeks to assert their independence, but the prudence and valour of Antipater crushed all attempts in the Lamian war, and established the Macedonian rule in Greece on a firm footing. At the same time Craterus was engaged in a war against the Ætolians, when news arrived from Asia which induced Antipater to conclude peace with them; for Antigonus reported that Perdiccas contemplated making himself sole master of the empire. Antipater and Craterus accordingly prepared for war against Perdiccas, and allied themselves with Ptolemy the governor of Egypt. Antipater crossed over into Asia in 321; and while still in Syria, he received information that Perdiccas had been murdered by his own soldiers. Antipater now, as sole regent, made several new regulations, and having commissioned Antigonus to continue the war against Eumenes and the other partisans of Perdiccas, returned to Macedonia, where he arrived in 320. Soon after he was seized by an illness which terminated his active career 319 B.C. Passing over his son Cassander, he appointed Polysperchon regent, a measure which gave rise to much confusion and ill feeling.

ANTIPHILUS, a painter of the 4th century before Christ, who was placed by the ancient critics in the highest rank after Apelles and Protogenes. He was born in Egypt, taught by Ctesidemus, and patronised by Philip of Macedon, and Ptolemy, son of Lagus. Jealousy is said to have led him to bring a false accusation against Apelles, which resulted, according to the story, in his being handed over to his rival as a slave. In style the two artists were strongly opposed; Antiphilus being remarkable for a certain quickness of conception, facility of execution, and lightness of treatment.

ANTIPHON, the most ancient of the ten Athenian orators contained in the Alexandrine canon. He was born 480 B.C. at Rhamnus. During the Peloponnesian war he was several times entrusted with the command of detachments of the Athenian forces, and took an active part in the political affairs of Athens. He had a hand in the overthrow of the democracy, and the establishment of the oligarchy of the Four Hundred, 411 B.C.; but as the new government was soon after changed, Antiphon was accused of high treason, and put to death. He must be regarded as the founder of political oratory at Athens, for he was the first that reduced the art of the orator to definite rules and principles. He wrote speeches for others, but never addressed the people himself except at his own trial. Seventeen orations bearing his name are extant, but two or three of them may be spurious. They are printed in the various collections of the Greek Orators. From this Antiphon the orator we must distinguish two others: the one a philosopher, mentioned by Xenophon (*Memor.*, i. 6), who is said to have written about dreams; and the other, a tragic poet, who lived at the court of the elder Dionysius.

ANTIPHONY (ἀντί, and φωνή, a voice), a species of psalmody in which the choir or congregation, being divided into two parts, sing alternately. The peculiar structure of the Hebrew psalms renders it probable that the antiphonal method originated in the service of the ancient Jewish Church. According to the historian Socrates, its introduction into Christian worship was due to Ignatius (died, 115 A.D.), who in a vision had seen the angels singing in alternate choirs. In the Latin Church it was not practised until more than two centuries later, when it was introduced by Ambrose, bishop of Milan, who compiled an *antiphonary*, or collection of words suitable for antiphonal singing. The antiphonary still in use in the Roman Catholic Church was compiled by Gregory the Great (590 A.D.)

ANTIPODES, a word of Greek derivation (ἀντί, against, opposed to, πόδες, feet),—from the inhabitants walking feet to feet,—is a relative term applied to any two peoples or places on opposite sides of the earth, so situated that a line drawn from the one to the other passes through the centre of the globe and forms a true diameter. Thus, the North Pole is exactly antipodal to the South. Any two places having this relation—as London and, approximately, Antipodes Island, near New Zealand—must be distant from each other by 180° degrees of longitude, and the one must be as many degrees to the north of the equator as the other is to the south. Noon at the one place is midnight at the other, the longest day corresponds to the shortest, and mid-winter is contemporaneous with mid-summer. In the calculation of days and nights, midnight on the one side may be regarded as corresponding to the noon either of the *previous* or of the *following* day. If a voyager sail eastward, and thus anticipate the sun, his dating will be twelve hours in advance, while the reckoning of another who has been sailing westward will be as much in arrear. There will thus be a difference of twenty-four hours between the two. In this way the Portuguese in Macao are a day before their Spanish neighbours in the Philippine Islands.

ANTIQUE, denoting etymologically anything that is ancient, is conventionally restricted to the remains of Greek and Roman art, such as sculptures, gems, medals, seals, &c. In this limited sense it does not include the artistic remains of other ancient nations, or any product of classical art of a later date than the fall of the Western Empire.

ANTIQUITIES. In keeping with its derivation, the word "antiquities" had for long a wide and general acceptation, embracing everything belonging to the knowledge of the remoter past. The range of the term has been gradually lessened, and a distinction has grown up between history on the one hand and antiquities on the other, though the line of demarcation is not of the most definite kind. Dr Arnold made the distinction between the historian and the antiquary to consist in this, that the historian studied the past for the sake of its bearing on the present, while the antiquary was content to investigate it for its own sake alone. It might rather be said, however, that the historian is concerned with the activities of the past, the antiquary with the products—the one with the progress and variation of the creative processes, the other with the perceptible and permanent results. In the vast range of subjects with which both classes of inquirers have to do,—religious rites, social customs, legal forms, architectural remains, sculptures, paintings, and so on,—it is plain that the more decidedly anything takes outward form the more undoubtedly it is the property of the antiquary rather than of the historian; and thence it has happened that the antiquary is not unfrequently thought of as having little concern with anything beyond purely material relics.

With respect to its treatment of the past three periods in a nation's history may be roughly distinguished—the period of emotional interest, the period of neglect, and the period of scientific attention. To the last of these the true antiquarian spirit belongs. Of the prevalence of this spirit in the classical ages of Greece and Rome we have but little evidence, though a considerable interest in archæological subjects was manifested by the greater historical intellects, such as Thucydides, Polybius, or Livy. But in the Alexandrian school there was a great, though somewhat irregular, development of antiquarianism, which acquired more of a scientific character from its being rather cosmopolitan than national.

At the revival of learning, when such enthusiasm was felt for everything classical, the relics of Greece and Rome were carefully collected and preserved; but it was some time before a transition took place from classical to national antiquarianism; and hence it is that the earliest literature of archæology is almost solely confined to the classical area. Manutius the younger (1511–1574), Sigonius (1520–1584), Meursius (1579–1639), Gruter (1560–1627), Gronovius (1645-1716), Graevius (1632–1703), Pitiscus (1637–1727), &c., kept up the line of laborious scholarship which laid the massive foundations of our present archæological erudition. The discoveries at Herculaneum (1713) and Pompeii (1755) gave a great impulse to such studies in general, besides supplying a special field of inquiry for such men as Venuti, Jorio, Bayardi, Rossini, and Ciampitto, Mazois, Gau, Gell, Barré, Fiorelli, Overbeck, Dyer, Monier, Garrucci, &c. The names of Heeren, Muller, Niebuhr, Creuzer, Boeckh, Hartung, and Zumpt are well known to all who are familiar with the subject of classical antiquities; and to these may be added Curtius, Waddington, Braun, Lasaulx, Le Bas, Roulez, Rangabé, Schömann, Canina, Panofka, Becker, Marquardt, and Lange. The results of their labours have been collected in such books as Pauly's *Encyclopädie der classischen Alterthumswissenschaft;* Smith's *Dictionary of Greek and Roman Antiquities;* and Daremberg and Saglio's *Dictionnaire des Antiquités grecques et romaines.* The capitals of Greece and Italy have naturally attracted particular attention to themselves. On Rome we have the special works of Desgodetz (1682), Piranesi (1784), Overbeck, Rossini, Reber, Dyer, Reumont, Nibby, besides the famous *Beschreibung* by Bunsen, Platner, Gerhard, Röstell, &c.; on Athens those of Leake, Forchhammer, Wordsworth, Stuart and Revett, Beulé, Laborde, &c. In connection with Etruscan antiquities, Micali, Dempster, Inglirami, Dennis, Hamilton, Heyne, Lanzi, and Raoul-Rochette are well known. The mysteries of the Egyptian monuments have found interpreters in Young, Champollion, Bunsen, Letronne, Lenoir, Leemans, Sharpe, &c.; while the marvels of Assyria have employed the energies of such men as Botta, Layard, Rawlinson, Munter, Grotefend, Rask, Burnouf, Lassen, Westergaard, Hincks, De Saulcy, Holtzmann, Haug, Spiegel. The antiquities of the northern nations of Europe have been treated by Mallet, Thorlacius, Nyerup, Werlauff, Worsaae, Thomsen, Brunius, Grupen, Heineccius, Roessig; those of France by Montfaucon, Caylus, Martin, Sauvagère, Ramé, Lajard, Renouvier, Didron, Gailhabaud, Gilbert, Beugnot, Cochet, and a multitude of others. The Russian antiquities have been magnificently represented in a great work issued by order of the Government.

In our own country the names of Leland, Camden, Hearne, Dugdale, Grose, and Roy, are not forgotten in the newer fame of Fosbrooke, Palgrave, Ellis, Wright, Stuart, Wilson, Brand, Lodge, Laing, Bateman, &c. For a knowledge of American antiquities we are largely indebted to Davies, Squier, Lapham, Haven, Rosny, Stephens; and for those of Mexico to Ranking.

In what are called ecclesiastical antiquities, besides the older works of Ugolinus, Canisius, and Bingham, we may mention Buchon, Bourassé, Martigny, Guenebault. The names of Lubbock and Tylor are especially famous in those inquiries which relate to the general condition of primeval humanity.

Associations of various kinds have naturally been formed by scholars interested in archæological pursuits for the promotion of their favourite studies, and a large number of periodical publications have been established, partly in connection with such associations, and partly as matters of commercial speculation.

As early as 1572, in our own country, a sort of society was formed by Bishop Parker, Sir Robert Cotton, William Camden, and a few kindred spirits, for the preservation of the national antiquities, and it continued to exist till 1604, when it was broken up by James I., who was afraid that it might degenerate into a political association. Papers on subjects discussed by them have been preserved in the Cottonian library, and were printed by Hearne, in 1720, as *A Collection of Curious Discourses*, and again, in 1771, by Sir Joseph Ayloffe, with considerable additions. In 1707 Humphry Wanley and a number of other gentlemen began to meet together for a similar purpose, and next year they received the co-operation of the brothers Gale, Dr Stukeley, Rymer, &c. In 1717 they were reconstituted, and in 1750 they obtained a charter from George II. as the *Society of Antiquaries of London.* In 1780 they were presented by George III. with apartments in Somerset House in the Strand. The council consists of twenty members and a president, who, during his tenure of office, is one of the trustees of the British Museum.

The *Society of Antiquaries of Scotland* was founded in 1780, and has the management of a large national Antiquarian Museum in Edinburgh. In Ireland there is a *Royal Historical and Archæological Association*, which holds its meetings at Kilkenny. The *Société des Antiquaires de France* was formed, in 1813, by the reconstruction of the *Académie Celtique*, which had been in existence since 1805 In Germany there are a large number of societies that, under the name of *Historische Vereine*, embrace the study of antiquarian subjects, and keep up a connection with each other through the *Correspondenzblatt des Gesammtvereins der deutschen Geschichts- und Alterthumsvereine*, published since 1853 at Stuttgart. There is a well-known *Société Royale des Antiquaires du Nord* at Copenhagen. Similar associations, far too numerous to mention, have been formed in all countries of European civilisation.

The word *antiquarius* first appears in the later Roman classics (Tacitus, Suetonius, Juvenal), with the signification of an affecter of old words and phrases. In the Middle Ages it was employed as the designation of one who was skilled in copying ancient manuscripts; and in modern German it has kept, in the form *Antiquar*, the cognate meaning of a dealer in old books.

ANTISEPTICS (ἀντί, against, and σηπτός, putrid, from σήπω, to make rotten), substances which have the property of preventing or arresting putrefaction in dead animal or vegetable matter. The access of air, together with a moderate amount of warmth and of moisture, are necessary to the occurrence of the putrefactive changes, which consist essentially in the breaking up of the complex organic material, and the formation of new and simpler combinations among its constituent elements. During the process various gases and vapours are evolved, and the lower forms of animal and vegetable life are observed to grow and multiply in the putrefying substance. The exciting causes of putrefaction have long formed a subject of scientific discussion, two widely-different theories being maintained respecting them. By the one, the changes which occur during the process are held to be from the first the result of chemical decomposition in the organic substance, whose atoms are in a state of motion or activity, which is capable of being communicated by catalytic action to other organic material in contact with it (Liebig); while, further, it is asserted that minute living organisms may be evolved from the dead material as the result of these chemical transformations. By the other theory, which is founded mainly upon the researches of Pasteur, the putrefactive changes are ascribed to the agency of organised germs ever present in the atmosphere, which, finding a suitable nidus in the putrescible material, grow and multiply, producing the chemical decompositions as the result of their action. Putrefaction, it is further maintained, may be entirely prevented by means which exclude the access of germs. The subject derives much interest and importance from its relation to the doctrines of the origin of life, as well as to questions concerning the sources of contagion and epidemic disease, and continues to the present time a matter of keen inquiry and experiment among physiologists. (See BIOLOGY.)

Putrefaction may be prevented by removing one or more of the conditions essential to its occurrence. Thus, by exclusion of the atmosphere, dead matter, which would speedily undergo decomposition, may be kept intact for an indefinite length of time, as shown in the method of preserving meat by hermetically sealing the jars after the expulsion of the air by heat. Again, the preservative influence of a low temperature is well known; and extreme cold is a powerful antiseptic, as proved in the case of the frozen mammoths of northern Asia. Furthermore, the abstraction of moisture will prevent corruption in dead matter. In warm and dry climates animal food may be preserved by exposure to the sun. In the ancient practice of embalming the dead, which is the earliest illustration of the systematic use of antiseptics, the moister portions of the body were removed before the preservative agents were added. (See EMBALMING.) Numerous chemical substances have the power of counteracting the putrefactive process. Many of these have been long known and used for this purpose. In embalming, besides the application of various aromatics and resins, the body was washed with cedar oil and natron (soda), and pitch or tar were used as antiseptics. Pitch was used by the Romans in wine-making to control the fermentive process. The fumes of sulphur were largely employed by the ancients for purposes of purification, while common salt has been known and used for ages as one of the best preservatives from decay. The mineral acids possess antiseptic properties, as do also many of the metallic salts—the chloride of zinc, in the form of Sir W. Burnet's disinfecting fluid, being one of the most potent of them. Alcohol is well known for its power of preserving animal substances from decay. Quinine has been found to possess strong antiseptic properties. The tar products, notably carbolic acid, are among the most approved and extensively used of all antiseptic agents. The various substances named possess the power of preventing putrefaction in dead animal or vegetable matter, and to a greater or less degree of arresting it where already begun. They likewise exert a similar action on the analogous process of fermentation. They differ from mere disinfectants, which destroy the emanations from putrescent material, but do not necessarily arrest the progress of decay. (See DISINFECTANTS.) Some antiseptics, however, such as sulphurous acid, are powerful disinfectants also; while others, such as quinine, have no disinfectant properties at all. Various opinions are entertained regarding the *modus operandi* of antiseptics. By those who hold the purely chemical theory of putrefaction they are believed to operate in different ways according to their chemical properties; thus, sulphurous acid is said to act by deoxidising the putrescible matter; the mineral acids and metallic salts by combining with the substance, and forming a permanent compound; and the tar acids in a similar manner. On the other hand, the supporters of the germ theory maintain that carbolic acid, and indeed all true antiseptics, produce their effect by acting as poisons to the infusorial organisms which are held to be essential to the occurrence of the putrefactive process.

One of the most important applications of antiseptics has been their introduction into medical and surgical practice. Although their internal administration, with the view of counteracting diseases believed to be due to morbid poisons, has not hitherto yielded any marked practical result, their employment in the treatment of wounds has, in the hands of Professor Lister of Edinburgh, attracted much interest, and has exercised an important influence on surgical practice during the past ten years. Professor Lister, adopting the germ theory of putrefaction, and regarding many of the evils arising in connection with open wounds as the result of putrid discharges, produced by the agency of atmospheric germs, seeks to exclude the access of these to wounded surfaces by the employment of antiseptics, particularly carbolic acid, the power of which in destroying living organisms is undoubted. Dressings of gauze, made antiseptic by previous treatment with strong carbolic acid, are applied to wounds. The acid well diluted with water is likewise employed as a lotion, and, during the dressing of wounds and the performance of operations, is also applied in the form of spray to the surrounding atmosphere, with the object of preventing all access of germs. Boracic acid is also employed by Mr Lister as an antiseptic. The chief benefits claimed for this method of treatment are, that wounds, however extensive, may heal without the occurrence of putrefaction in the discharges, and that thereby the risks of blood poisoning (pyæmia, &c.) are reduced to a minimum. Although the antiseptic system in surgery is but on its trial, and its practical advantages over the methods of treatment in general use are still questioned by many high authorities, it has already obtained wide repute, and is extensively employed by surgeons both in this and other countries. (J. O. A.)

ANTISTHENES was the earliest Greek expositor of a philosophy and mode of life to which the name Cynicism soon came to be applied. Though a native of Athens, he was the son of a Thracian mother; and it was in the gymnasium of Cynosarges, to which the half-breeds were restricted, that he is said to have taught. From that place he and his followers probably received the name Cynic; but the popular derivation of the word connected it with the dog, whose shamelessness and importunity many of their actions seemed to imitate. In the time of Diogenes the name was firmly fixed as a nickname, and even adopted by the Cynics themselves.

Antisthenes was apparently born some years before the Peloponnesian war began, and from his remark on the rejoicings after the battle of Leuctra (371 B.C.)—that the Thebans were like a pack of schoolboys who had thrashed their master—it may be inferred that he lived on nearly to the middle of the 4th century B.C. He may be regarded as an elder contemporary of Plato. In youth he studied rhetoric under Gorgias, perhaps also under Prodicus and Hippias. These studies bore fruit, not merely in the stylistic ability which made his writings eulogised by later critics, but more especially in the doctrine he afterward held, that the study of names was the first step in education. He opened a school of his own, and was on the way to distinguish himself in the usual course of oratory, when he met with Socrates, and his views of life underwent a change. From that time he became the inseparable admirer of Socrates, to hear whom he walked every morning from Piræus to Athens, a distance of about 5 miles.

Antisthenes was poor, and lived in the midst of a commercial population which had suffered severely from the disasters attending the downfall of the Athenian empire. He became the philosopher of the proletariate, carrying into the haunts of the indigent and the vicious those principles which had been spreading in wealthier circles, and modifying them to suit altered circumstances. His earlier culture had always been more literary and rhetorical than strictly philosophical, and he never attained a mastery over metaphysical problems. Aristotle speaks of him as uneducated and simple-minded; and Plato has been understood, in more places than one, to refer to the zeal without knowledge with which he dwelt upon the difficulties of dialectic. Words and names were to him more important than thoughts The puzzle of the one and the many, which then was so prominent, led him to the strange conclusion that we can never say that one thing (or name) is another, as that a tree is green, but only that a tree is a tree. Such an adhesion to identical propositions as the sole form of judgment led him to deny the possibility of contradiction altogether. He objected to the Platonic theory of the substantive existence of relative and qualitative terms, such as good or beauty The dramatising legend shows him putting out his criticism thus: "Plato," he said, "I can see a horse, and I can see a man; but humanity and horsehood I cannot see." "True," replied Plato, "you have the eye which sees a horse and a man, but the eye which can see horsehood and manhood you have not." The idea expressed by the so-called abstract term was to Antisthenes merely subjective—a bare conception (ψιλὴ ἔννοια) in the mind. Antisthenes, in short, opposes a crude Realism to the Idealism of Plato The attitude of Antisthenes towards intellectual philosophy is in the main negative, and the general result he comes to is that logical or metaphysical investigations which go beyond name are unfruitful and frivolous.

A certain training is, however, necessary before a man can become what Antisthenes wishes him to be—his own master, independent of all external goods and social ties. This preparation consists in the laborious endeavour (πόνος) to raise himself above those external circumstances of human life which reflection shows to be useless and vain show (τῦφος). We must separate what we really are by nature from our artificial surroundings, so as to discover the minimum of real wants in life; and then fixing our mind on that standard, we must discard whatever is desirable only because popular opinion calls for it. Seeing that nature needs but little, and that this little is easily attained, if we do not insist on the delusions which attend it, the wise man will, it is true, gratify the natural cravings, but will not do more. These inevitable appetites of sex and food being satisfied, without the additions and refinements which art and fashion require, he will renounce pleasure as such. In the paradoxical language of Antisthenes, he would rather plunge into insanity than into pleasure. His aim must be to become, as much as may be, independent of everything outside, using it as needful, but not desiring it as a gratification. Such a mastery of self is what is called virtue, and is enough for happiness. It is hard to win, but once attained it can never be lost. The Cynic is one who surrenders the city of human life, with its varied scenes, on account of the difficulty of keeping his ground, and who is content if he can hold out the barren rock of the citadel as a soldier, constantly on the watch and *in procinctu*. Unfortunately this conception of a minimum of needs is somewhat vague, and allows many degrees. Diogenes could criticise and improve upon Antisthenes, and the Indian gymnosophists pointed out that Diogenes himself exceeded the strict demands of nature.

Antisthenes, though he did not encourage the formality of a school, and drove away the curious or enthusiastic with his staff, taught others by his example and by his caustic words. The Cynic was something of a missionary. He adopted a peculiar garb, at first perhaps for reasons of economy, but subsequently as a symbol of his profession. A rough cloak, which could be doubled to counterfeit an inner garment, and served the purposes of a night covering; a wallet, in which provisions could be carried; a staff to support his steps, and perhaps something from which to drink, constituted the property of the bare-footed Cynic; and to these was afterwards added a long beard. The successors of Antisthenes lived, like mendicant friars, on the alms of the public, and wandered from place to place, sleeping by night on the steps of public buildings, or occupying any vessel or tub which might suit their purpose. Antisthenes himself seems not to have been specially extravagant in conduct; but the later Cynics, who were without his early culture, made it a point to disregard all decency and social conventions. Whatever they had to do they deemed it their duty to do in public—at least such is the tenor of many tales. The wise man, they held, would follow another law than that of his city; he was a citizen of the world. Sexual desires he would unquestionably have to satisfy, but in the most convenient way, without regard to sentimental objections or to beauty—the uglier the better. Some, at least, of the Cynics maintained the advisability of a community of wives. They allowed to no ceremonies more than a relative force. According to Diogenes, the practice of cannibalism among certain tribes shows that the prohibition against eating human flesh is no part of the code of nature.

So far the Cynics taught practically. But they were also great in repartee and sarcasm. The fine touch of Socratic irony, which had given offence by talking occasionally about pots and pans, was succeeded by a rough and sometimes gross satire, which scrupled not to deal with matters viler still. Antisthenes, it is said, had some powers of social attraction, but if it were so, his successors were more marked by the severity of their rebukes. From the Homeric poems, the Bible of the Greeks, they drew many of the weapons of their warfare, parodying its language, and applying it to suit their own circumstances. Public manners, men, and measures were assailed in no merciful spirit. Antisthenes compared the cry of democratic politicians to the speech in which the hares demanded equality of rights from the lion. He was equally at odds with the æsthetic and literary tendencies of his time. Aristippus, Plato, and Isocrates were among his literary enmities. Nor was he less trenchant in his criticisms of popular superstitions, of soothsayers, and mystery-mongers. When the priest dilated in his sermon on the blessedness of the other world for the initiated, Antisthenes interrupted him with the words: "Why don't you die, then?"

Antisthenes was a voluminous writer; his works according to Diogenes Laertius, filled ten volumes. Of these scarcely anything is left. They seem to have been on various subjects, many of them being apparently a moralising interpretation of the poems of Homer. We can base our estimate of Antisthenes only on the sayings attributed to him, and, above all, to his follower Diogenes.

The great age of Cynicism in Greece is the century from 400 to 300 B.C. Diogenes, who succeeded Antisthenes, carried the exaggeration still further, and yet, in the story of the education of the children of Xeniades by him, there are traits which anticipate the educational theory of Rabelais and Rousseau. Crates, who succeeded Diogenes, voluntarily abandoned his possessions; and Hipparchia was so enamoured of Cynical life, that she refused her wealthy suitors, and married the landless and ill-favoured Crates. They were both notable features in the school, which includes the names of Monimus (a slave who was attracted by the fame of Diogenes), Onesicritus, Metrocles, and Menippus. In Menedemus the Cynical succession disappears, perhaps combining with the Megaric. For more than three centuries the name continued a tradition, when in the 1st and 2d centuries of the Christian era it was revived. The majority of the Cynics of that date were a worthless set of vagabonds, who used the garb and the name as a cover for all iniquities. They may be compared to the mendicant orders in the worst days of their corruption. But amongst them two or three names have a brighter light thrown upon them. Demetrius is lauded by his contemporary Seneca, and about a hundred years later Demonax is enthusiastically presented to the world by Lucian. There is much of the old Cynic in these descriptions; but the men were more eclectic, and had in some respects followed the advance of the general culture. Cynicism lasted for a few centuries longer, but never contributed anything to philosophy properly so called. It was a mode of life rather than a theory; and it sank before the monasticism and asceticism which marked certain directions in the history of the Christian church. (W. W.)

ANTITHESIS (ἀντίθεσις) is, in rhetoric, the bringing out of a contrast in the meaning by an obvious contrast in the expression, as in the following:—"When there is need of silence, you speak, and when there is need of speech, you are dumb; when present, you wish to be absent, and when absent, you desire to be present; in peace you are for war, and in war you long for peace; in council you descant on bravery, and in the battle you tremble." Antithesis is sometimes double or alternate, as in the appeal of Augustus:—"Listen, young men, to an old man to whom old men were glad to listen when he was young." The force of the antithesis is increased if the words on which the beat of the contrast falls are alliterative, or otherwise similar in sound, as—"The fairest but the falsest of her sex." There is nothing that gives to expression greater point and vivacity than a judicious employment of this figure; but, on the other hand, there is nothing more tedious and trivial than a pseudo-antithetical style. Among writers in our own language who have made the most abundant use of antithesis, are Pope, Young, Johnson, and Gibbon; and, to an egregious extent, Lily in his *Euphues*. It is, however, a much more common feature in French than in English; while in German, with some striking exceptions, it is conspicuous by its absence.

ANTITYPE (ἀντίτυπος) denotes a type or figure corresponding to some other type. It is in this sense of *copy* or *likeness* that the word occurs in the New Testament (Heb. ix. 24; 1 Peter iii. 21). By theological writers *antitype* is employed to denote the reality of which a *type* is the prophetic symbol. Thus, Christ is the antitype of many of the types of the Jewish ritual. By the fathers of the Greek Church antitype is employed as a designation of the bread and wine in the sacrament of the Lord's supper.

ANTIUM, a city on the Italian coast, about 33 miles S. from Rome. Its site is now occupied by the village *Porto d'Anzio*, or *d'Anzo*. Founded, it is supposed, by Pelasgians, it became connected with the Latin League, and about the beginning of the 4th century before Christ passed into the hands of the Volsci. As the chief city of this people it continued, in spite of repeated defeat, to carry on, with intervals of peace, a pertinacious war against the Romans till the year 338 B.C., when it was finally subdued, and garrisoned by a Roman colony, its ships being destroyed, and their *rostra* or beaks sent to ornament the speaker's platform in the Forum. Towards the close of the republic it was again a beautiful and flourishing town, greatly resorted to by the wealthier Romans. There was a magnificent temple to Fortune, and others to Æsculapius, to Venus, and to Apollo. It was patronised by the emperor Augustus, and became the birth-place of Caligula and Nero. The latter enriched it with a fine artificial harbour, and it was afterwards indebted to Antoninus Pius for an aqueduct. It seems to have fallen into decay about the 5th century; and the attempts made in the 17th by Innocent XII. to restore it had only a temporary success. It is now the property of the Borghese family, and is a favourite bathing-place in the early summer months. Among the ancient remains that have been discovered here are the *Apollo Belvedere*, and the *Borghese* or *Fighting Gladiator*.

ANTIVARI, or BAR, a town of Turkey, in Albania, situated on the Adriatic Sea, 18 miles N.W. of Scutari. It possesses a castle that is now of no value as a fortification, and a good harbour for vessels of light draught, which accommodates a considerable trade in the products of Albania. It is the seat of a Roman Catholic bishop. Population about 6000.

ANTONELLO DA MESSINA. Of the events of this celebrated painter's life we know little more than that he was probably born at Messina about the beginning of the 15th century; lived and laboured at his art for some time in his native country; happening to see at Naples a painting in oil by Jan Van Eyck, belonging to Alfonso of Aragon, was struck by the peculiarity and value of the new method; set out for the Netherlands to acquire a knowledge of the process from Van Eyck's disciples; spent some time there in the prosecution of his art; returned with his secret to Messina about 1465; probably visited Milan; removed to Venice in 1472, where he painted for the Council of Ten; and died there about 1493. His style is remarkable for its union—not always successful—of Italian simplicity with Flemish love of detail. His subjects are frequently single figures, upon the complete representation of which he bestows his utmost skill. There are still extant—besides a number more or less dubious—twenty authentic productions of his pencil, consisting of "Ecce Homos," Madonnas, saints, and half-length portraits, many of them painted on wood. The finest of all is said to be the nameless picture of a man in the Berlin Museum. Antonello exercised an important influence on Italian painting, not only by the introduction of the Flemish invention, but also by the transmission of Flemish tendencies.

ANTONIDES, HANS [JAN VAN DER GOES], a Dutch poet, was born April 3, 1647, at Goes, in Zealand, of poor but respectable parents. They removed to Amsterdam when he was about four years old, and he there enjoyed the tuition of Hadrian Junius, and James Coccceius. He was only nineteen when he attracted attention by his tragedy, *Trazil, of overrompelt Sina*—Trazil, or the Conquest of China. The venerable Vondel called him his son, and said he would have been proud of being the author of his *Bellone aan Band*. His parents designed him for an apothecary; but Buisero, one of the lords of the admiralty at Amsterdam, defrayed his college expenses, and enabled him to take the degree of doctor of physic. He practised with success, and established his poetic fame by his *Y-stroom*, an epic on the river Y. He died on the 18th of September 1664. His writings are remarkable for their warmth of fancy and vigour of expression, which sometimes degenerate into extravagance and bombast. His complete works were printed at Amsterdam in 1714, 4to, with a sketch of his life.

ANTONINI ITINERARIUM, a valuable register, still extant, of the stations and distances along the various roads of the Roman empire, seemingly based on official documents, which were probably those of the survey organised by Julius Cæsar, and carried out under Augustus. The work has plainly undergone various revisions down to the end of the 3d century. What connection any of the Antonines may have had with it is unknown. The whole Itinerary was printed by H. Stephens at Paris, 1512, and by Wesseling at Amsterdam, 1735. The part relating to Britain appeared at London, 1799, as *Iter Britanniarum*, with a new commentary, by Thomas Reynolds.

ANTONINUS LIBERALIS, a Greek grammarian, who probably lived about 147 A.D. His work, *μεταμορφώσεων συναγωγή*, consists of forty-one tales of mythical metamorphoses, and is chiefly valuable for the study of Greek mythology. One of the best editions is that of Koch, Leipsic, 1832, 8vo.

ANTONINUS, MARCUS AURELIUS. See AURELIUS, MARCUS.

ANTONINUS, TITUS AURELIUS FULVUS BORONIUS ARRIUS, surnamed PIUS, was the son of Aurelius Fulvus, a Roman consul, whose family had originally belonged to Nemausus (Nismes). He was born near Lanuvium, 86 A.D., and, having lost his father, was brought up under the care of Arrius Antoninus, his maternal grandfather, a man of integrity and culture, and on terms of friendship with the younger Pliny. Having filled with more than usual success the offices of quæstor and prætor, he obtained the consulship in 120 A.D.; was next chosen one of the four consulars for Italy; greatly increased his reputation by his conduct as proconsul of Asia; acquired much influence with the emperor Hadrian, by whom he was at length adopted as his son and successor in February 138 A.D.; and a few months afterwards, on Hadrian's death, was enthusiastically welcomed to the throne by the Roman people, who, for once, were not disappointed in their anticipation of a happy reign. For Antoninus came to his new office with simple tastes, kindly disposition, extensive experience, a well-trained intelligence, and the sincerest desire for the welfare of his subjects. Instead of plundering the provinces to support his prodigality, he emptied his private treasury to assist the provinces. Instead of exaggerating into treason whatever was susceptible of unfavourable interpretation, he turned the very conspiracies that were formed against him into opportunities of signalising his clemency. Instead of stirring up the persecution of the Christians, and gloating over the sufferings of their martyrs, he extended to them the strong hand of his protection through all the empire. Rather than give occasion to that oppression which he regarded as inseparable from an emperor's progress through his dominions, he was content to spend all the years of his reign in Rome, or its neighbourhood. Under his patronage the science of jurisprudence was cultivated by men of high ability, and a number of enactments were passed in his name that are equally characteristic of his humanity and his justice. Of the public transactions of this period we have but scant information, but, to judge by what we possess, those twenty-two years were not remarkably eventful. No conquests of importance were attempted, and there were no very dangerous attacks to repel, though all round the frontiers a kind of simmering hostility produced a succession of minor invasions and revolts. The one military result which is of interest to us now is the building of the wall of Antoninus from the Forth to the Clyde. In his domestic relations Antoninus was not so fortunate. His wife, Faustina, has almost become a by-word for her lack of womanly virtue, though, either through his ignorance of her conduct, or in spite of his being aware of it, she seems to have kept her hold on his affections to the last. On her death he did honour to her memory in many ways; but in none more remarkable than by the foundation of a charity for orphan girls, who bore the title of *Alimentariæ Faustinianæ*. He had by her two sons and two daughters; but they all died before his elevation to the throne, except Annia Faustina, who became the wife of his successor, Marcus Aurelius, and deepened the infamy of the name she inherited from her mother. Antoninus died of fever on the 7th of March 161, giving, as we are told, the key-note to his life in the last word that he uttered when the tribune of the night-watch came to ask the password—*Æquanimitas*. The only account of his life handed down to us is that of Julius Capitolinus.

Antoninus Pius.

ANTONINUS, WALL OF, called GRAHAM'S DYKE by the natives of the district through which it passed, is the name given by historians to that series of defensive posts, connected by a rampart and a wall, which at one time extended across the island from the Firth of Clyde on the west to the Firth of Forth on the east. The former of these appellations it has received from the Roman emperor in whose reign it was erected; the origin of the latter is more doubtful, a probable opinion being that which regards it as a corruption of the Celtic *greim*, a place of strength, and *diog*, a trench or rampart.

We are informed by Tacitus that Agricola, during his fourth summer in Britain (81 A.D.), occupied himself in consolidating his previous conquests, and that for this purpose he caused a series of detached forts to be built on the isthmus that joins the two firths as a barrier against the still unconquered Caledonians of the north. It was along, or almost along, the same line, that one of his successors in the command of the Roman troops in Britain raised the more permanent military work known as Antonine's wall.

The writer of the life of the emperor Antoninus Pius in the *Historiæ Augustæ Scriptores Sex*, usually supposed to have been Julius Capitolinus, expressly states that Lollius Urbicus, a legate of that emperor, erected, after several victories over the Britons, "another rampart of turf" to check their inroads. No locality is specified, but a fragment of a stone, now in the museum of the university of Glasgow, has an inscription in which the name of this Lollius seems to occur. This fragment, and the numerous monumental records bearing the name of Antonine that have been discovered along its course, identify beyond all reasonable doubt the wall between the Forth and Clyde as that spoken of by the annalist, and furnish satisfactory proof of the correctness of its best-known name. And if a small pillar figured by Gordon, and at one time in the library of the university of Edinburgh, was found, as is probable, near the wall, it fixes the year 140 A.D. as the exact date at which the portion of the work connected with the pillar was executed.

In addition to the annalist just mentioned, several other ancient historians are supposed to allude to Antonine's wall, but their brief statements are so vague that further reference to what they say is unnecessary. Of mediæval writers Bede is almost the only one who notices it, but he erroneously ascribes its erection to the natives of the south acting according to advice given them by the Romans. Timothy Pont, who early in the 16th century personally surveyed a large portion of Scotland while gathering materials for his projected *Scottish Atlas*, drew the attention of antiquaries to this memorial of Roman times, though to him, as well as to his successors in antiquarian research for nearly a century, it was known as "Agricola's vallum, or Graham's Dike." It is to Gordon that the merit must be awarded of having been the first to give to the world a satisfactory account of the "wall of Antoninus Pius." A chapter of the *Itinerarium Septentrionale* is devoted to it, and plans are given of the principal forts, as well as engravings of the legionary tablets and other objects of interest that had, up to the author's day, been dug out of its ruins. Gordon was followed by Horsley and Roy, the latter of whom made in 1755 a new survey of it, which enabled him to correct Gordon in some particulars. Lastly, in the *Caledonia Romana* of Stuart, we have a complete and, on the whole, accurate description of the wall, with figures of all the sculptured stones found near its course up to the date at which he wrote.

The nature and appearance of the wall when perfect have been described by all these writers in very similar terms, though they differ somewhat as to the measurement of its several parts. "It consisted," says Stuart, "in the first place, of an immense fosse or ditch—averaging about 40 feet in width, by some 20 in depth—which extended over hill and plain in one unbroken line from sea to sea. Behind this ditch on its southern side, and within a few feet of its edge, was raised a rampart of intermingled stone and earth, strengthened by sods of turf, which measured, it is supposed, about 20 feet in height, and 24 in thickness at the base. This rampart was surmounted by a parapet, behind which ran a level platform for the accommodation of its defenders. To the southward of the whole was situated the military way—a regular causewayed road about 20 feet wide—which kept by the course of the wall at irregular distances, approaching in some places to within a few yards, and in others receding to a considerable extent." Along the entire line there were at least eighteen principal stations or forts, with smaller watchtowers in the intervening spaces. The rampart seems to have consisted for the most part of earth or turf, as stated by the annalist; but stone was, no doubt, employed in the building of the forts and watchtowers as well as in certain portions of the rampart itself.

Although in many parts of its course all traces of Antonine's wall have long been obliterated, the line along which it stretched has been mapped out by Gordon and others with sufficient accuracy. Commencing in the west on a height called Chapel Hill, near the village of Old Kilpatrick in Dumbartonshire, and now distant from the River Clyde about 150 yards, it ran eastwards, passing in succession Kirkintilloch, Croy, Castlecary, and Falkirk, and terminated at Bridgeness, a rocky promontory that projects into the Firth of Forth south of Borrowstounness in Linlithgowshire. Its eastern termination was long supposed to have been near the kirk of Carriden. In 1869, however, a sculptured legionary tablet, since deposited in the museum of the Society of Antiquaries of Scotland, was found at Bridgeness, in such a position that it is impossible to avoid the conclusion that the wall actually terminated there. Its entire length may be set down at about 36 English miles.

Of the sculptures found near or on the site of this wall a considerable number are records of the different portions of the work executed by the legionaries employed on it, and who mainly belonged to the second, sixth, and twentieth legions. Some of these tablets are in the museum of the university of Glasgow, and are of much interest, but the finest of them all is the Bridgeness one already referred to. From the number of Roman paces mentioned on the inscriptions, Horsley and others have attempted to determine the exact length of the work. Unfortunately for their purpose, the paces on the stones already discovered considerably exceed its whole length, and as we cannot suppose that all the monuments of this kind that were erected by the legionaries have been preserved and brought to light, we must conclude with Stuart that they had raised more than one memorial of the same piece of work.

How many years Antonine's wall continued to be the boundary of the Roman territories in Britain it is impossible to say, but there is every reason for believing that it was so for only a brief period.

ANTONIO, NICOLAO, a Spanish bibliographer, was born at Seville in 1617. After finishing his studies at Salamanca, he returned to Seville, and shut himself up in the royal monastery of Benedictines, where he devoted several years to writing his *Bibliotheca Hispanica*, a work in four vols. folio, two of which he published at Rome in 1672. The work consists of two parts: the one containing the Spanish writers who flourished before the end of the 15th century; the other—the part published by Antonio himself—treating of later writers. He was recalled to Madrid by Charles II., and died in 1684, leaving nothing but a magnificent library of over 30,000 volumes. The earlier volumes of his *Bibliotheca* were published in 1696 at the expense of Cardinal d'Aguirre, and under the superintendence of his librarian, Marti, who added notes in the name of the cardinal. An improved edition of the entire work, by F. P. Bayer, was published at Madrid in four vols. folio, in 1783–8.

ANTONIUS, MARCUS, the Roman orator, was born 143 B.C. After having filled the office of quæstor (113), he was appointed prætor in 104, and proprætor in the following year, the province of Cilicia being assigned to him. Here he was so successful in the war against the pirates, that a naval triumph was awarded him in 102. He was consul along with A. Postumius Albinus in 99, when he successfully opposed the agrarian law of the tribune Titius. He was censor 97, and held a command in the Marsic war in 90. Belonging as he did to the party of Sulla, he was put to death by order of Marius and Cinna when they obtained possession of Rome (87 B.C.). Antony's reputation for eloquence rests on the authority of Cicero, none of his orations being extant.

ANTONIUS, MARCUS [MARK ANTONY], grandson of Antonius the orator, and son of Antonius Creticus, seems to have been born about 83 B.C. While still a child he lost his father, whose example, however, had he been spared, would have done little for the improvement of his character. Brought up under the influence of the disreputable Cornelius Lentulus Sura, whom his mother had married, Antony spent his youth in profligacy and extravagance. For a time he co-operated with the reprobate Clodius in his political plans, chiefly, it is supposed, through hostility to Cicero, who had caused Lentulus, his stepfather, to be put to death as one of the Catiline conspirators; but he soon withdrew from the connection, on account of a disagreement which, appropriately enough, arose in regard to his relations to his associate's wife, Flavia. Not long after, in 58 B.C., he fled to Greece, to escape the importunity of his creditors; and at length, after a short time spent in attendance on the philosophers at Athens, found an occasion for displaying some of the better features of his character in the wars that were being carried on by Gabinius against Aristobulus in Palestine, and in support of Ptolemy Auletes in Egypt. A new chapter in his life was opened by the visit which he made to Julius Cæsar in Gaul (54 B.C.) Welcomed by the victorious general as a valuable assistant in his ambitious designs, and raised by his influence to the offices of quæstor, augur, and tribune of the plebs, he displayed admirable boldness and activity in the maintenance of his patron's cause, in opposition to the violence and intrigues of the oligarchical party. At length his antagonists prevailed, and expelled him from the curia; and the political contest became a civil war The Rubicon was crossed, Cæsar was victorious, and Antony shared in his triumph. Deputy-governor of Italy during Cæsar's absence in Spain (49), second in command in the decisive battle of Pharsalia (48), and again deputy-governor of Italy while Cæsar was in Africa (47), Antony was now inferior in power only to the dictator himself, and eagerly seized the opportunity of indulging in the most extravagant excesses of luxurious licentiousness,—excesses which Cicero depicted in the *Philippics* with all the elaborate eloquence of political hatred. In 46 he seems to have taken offence at Cæsar, because he insisted on payment for the property of Pompey which Antony professedly had purchased, but had merely appropriated. But the estrangement was not of long continuance; for we find Antony meeting the dictator at Narbo the following year, and rejecting the advances of Trebonius, who endeavoured to discover if there was any hope of getting Antony to join in the conspiracy that was already on foot. In 44 he was consul along with Cæsar, and seconded his ambition by the famous offer of the crown on the 15th of February, thus unconsciously preparing the way for the tragedy of the 15th of March. To the sincerity of his adherence to Cæsar the conspirators themselves bore witness on that memorable day, by the care which they took to keep him engaged without while the daggers were doing their work within. This was the second great epoch in Antony's life. A brighter prospect than ever was then opened to his ambition. By his eloquence—a hereditary gift—he managed to stir up the minds of the populace against the assassins of Cæsar, and drove them from the city. He made peace with the remaining representatives of the senatorial party, and almost seemed to have succeeded to the power and position of his unfortunate patron. But the youthful Octavius, whom Cæsar had adopted as his son, arrived from Illyria, and claimed the inheritance of his "father." Agreement was impossible, and war ensued. Octavius obtained the support of the senate and of Cicero; and the veteran troops of the dictator flocked to his standard. Antony was denounced as a public enemy; and the city gave its loudest applause to the tirades of his most eloquent accuser. His cause gradually lost ground, and at last seemed to be totally ruined when his army was defeated in the siege of Mutina (43 B.C.) But escaping to Cisalpine Gaul, he formed a junction with Lepidus, and they marched towards Rome with 17 legions and 10,000 cavalry. The wily Octavius now betrayed his party, and entered into terms with Antony and Lepidus. It was agreed that they three should adopt the title—so beautifully ironical—of *Triumviri reipublicæ constituendæ*, and share the power and the provinces among them. Gaul was to be Antony's; Spain fell to the lot of Lepidus, and Africa, Sardinia, and Sicily were to belong to Octavius. A conjunct proscription followed, each of the partners in the villanous design bartering the life of his friends for the pleasure of destroying his foes. The detested author of the *Philippics* was given up to Antony's revenge; and, according to Appian, the number of the victims amounted to 300 senators and 2000 knights. In the following year Antony and Octavius proceeded against the conspirators Cassius and Brutus, who still maintained themselves in Macedonia; and, in the battles of Philippi, stamped out the last embers of republican Rome. While Octavius returned to Italy, Antony proceeded to Greece, and thence to Asia Minor, for the sake of recruiting his funds, completing the subjugation of the eastern provinces, and obtaining satisfaction about the conduct of the Egyptian queen during the recent contest. On his passage through Cilicia in 41 he was visited by Cleopatra, who came to answer the charges in person. She sailed up the Cydnus in a gorgeous bark, with a fantastic and brilliant equipage, and brought all her allurements to bear on the heart of the voluptuous Roman. Her success was complete, and he who was to have been her judge, was led captive to Alexandria as her slave. All was forgotten in the fascination and delight of the passing hour; and feasting and revelry found perpetual and ever-varying renewal. At length Antony was aroused by the Parthian invasion of Syria, and the report of an outbreak between Fulvia his wife and Lucius his brother on the one hand and Octavius on the other. On arriving in Italy he found that the war was over, and Octavius the victor; and the chief cause of disagreement being soon after removed by the death of Fulvia, a reconciliation was speedily effected between the triumvirs, and cemented by the marriage of Antony with Octavia, the sister of his colleague. A new division of the Roman world was agreed on at Brundusium, Lepidus receiving Africa, Octavius the west, and Antony the east. Returning to his province, Antony was for a time successful; his general, Ventidius, beating the Parthians, and Socius, capturing Jerusalem and conquering Antigonus. But after another visit to Italy, during which the triumvirate was prolonged for five years, Antony sent away his wife, yielded himself completely to the evil influence of Cleopatra, indulged not only in licentiousness, but in tyranny, and allowed his affairs to be neglected or delayed. An expedition against the Parthians was a failure; but for this his success against Artavasdes, the Armenian king, in some measure compensated. Octavius at length determined to get rid of Antony, and had little need of invention to bring charges sufficient against him. About two years were spent in preparations and delays on both sides, and it was not till the year 31 that the fate of Antony was decided by the battle of Actium. Defeated and deserted, he once more sought refuge and repose in the society of Cleopatra, but was followed even there by his relentless rival. At first he made a gallant effort to defend himself, and partially succeeded. But convinced of the hopelessness of his position, and assured of the suicide of his mistress, he followed the example which he was falsely informed she had given (30 B.C.) Antony had been married in succession to Fadia, Antonia, Fulvia, and Octavia, and left behind him a number of children. A short but vivid sketch of Antony is given by De Quincey in his "Essay on the Cæsars," see his *Works*, ix. 57-59

ANTONOMASIA (ἀντονομασία) is, in rhetoric, the substitution of any epithet or phrase for a proper name; as "Pelides," or "the son of Peleus," for Achilles; "the Stagyrite" for Aristotle; "the author of *Paradise Lost*" for Milton; "the little corporal" for Napoleon the First; "Macedonia's madman" for Alexander the Great, &c. &c. Besides gratifying the taste for variety, it affords the opportunity of bringing indirectly into view facts or feelings that it is not considered desirable or expedient to express distinctly by themselves. The opposite substitution of a proper name for some generic term is also sometimes called antonomasia; as, a "Cicero" for an orator. In both cases the figure is akin to metonymy.

ANTRIM, a maritime county in the north-east corner of Ireland, in the province of Ulster, situated between 54° 26′ and 55° 12′ 16″ N. lat., and 5° 47′ and 6° 52′ W long. It comprises, without including the 50,803 acres under water, an area of 711,275 statute acres, of which 16,702 belong to the incorporated county of the town of Carrickfergus. There were, in 1871, 257,211 acres under tillage, 373,839 in pasture, 6717 in plantation, and 72,065 waste. The county presents a considerable line of coast to the Atlantic Ocean on the north, and to the Irish Channel on the east; while Belfast Lough and the river Lagan divide it from the county of Down on the south; and Lough Neagh and Lough Beg, together with the river Bann, form its boundaries on the west, except towards the mouth of the river, where a small portion of the county of Londonderry lies on the eastern bank.

In area Antrim is exceeded by eight other counties in Ireland, but in population by Cork and Dublin alone. A large proportion of the surface, especially towards the east, consists of mountains and bogs; and it is computed that about 120,000 acres are irreclaimable. The mountains, occupying about one-third of the county, stretch from south to north, and terminate on the northern shore in abrupt and almost perpendicular declivities. Among the principal heights may be mentioned Trostan, 1810 feet; Knocklayd, 1685; Divis, 1567; Agnew's Hill, 1558; and Slemish, 1457. They attain their greatest elevation near the coast, and have a gradual descent inland, so that many of the streams, with their sources near the sea, flow south and west into Lough Neagh. The mountainous region has a gentler inclination as it approaches the Bann, and is occupied by turf-bogs susceptible of improvement. Some of the valleys, especially that of the Lagan, extend to a considerable width, and are of great fertility. The most extensive level tracts of rich and well-cultivated land lie along the shores of Lough Neagh, and from Belfast to Carrickfergus, and thence to Larne, between the mountain range and the sea. The most remarkable cliffs are those of perpendicular basaltic columns, which extend for many miles along the northern shore, and are most strikingly displayed in Fair Head and the Giant's Causeway.

Lough Neagh, the largest lake in Europe, with the exception of Lake Ladoga, Lake Wener, and the Lake of Geneva, is principally in Antrim. It is about 20 miles in length, 12 in breadth, and 80 in circumference, with an area of 98,255½ statute acres, of which 50,025 belong to Antrim; its greatest depth is from 45 to 48 feet, and its surface is 48 feet above the level of the sea. The lower Bann, obstructed by weirs and rocks, being the only outlet for the waters of the lake, which is fed by the Maine, the Six-mile Water, and a number of smaller streams, the surrounding country is in winter liable to be damaged by floods. The waters of the Lough, or at least of the Crumlin, one of the streams flowing into it, have petrifying powers; and some of the petrifactions are very beautiful, take a good polish, and rival those of Antigua. North of Lough Neagh, and connected with it by the river Bann, is Lough Beg, or the "small lake," containing 3145 acres, partly in Antrim. It is generally 15 feet lower than the larger lake, which it excels in the diversified and pleasing scenery of its banks. The Bann and Lagan, both of which rise in the county of Down, are the only rivers of importance. Of those strictly belonging to Antrim, none are navigable. They are generally rapid streams, of great value for turning machinery. The chief indentations of the coast are Red Bay, Carnlough, Glenarm, and Lough Larne. About 7 miles from the north coast, opposite Ballycastle, surrounded by a wild and troubled sea, lies the island of Rathlin, 6½ miles in length and 1½ in breadth, of similar basaltic and limestone formation with the neighbouring mainland. About a fourth of its 3399 acres are arable, and it supports a population of 453. There is a lighthouse on it with a fixed light.

The climate of Antrim is very temperate. The average annual rain-fall at Belfast is about 33 inches.

The geology of Antrim is of considerable interest, both on account of its peculiar character, and because the arrangement and alternations of strata are laid bare with more than usual distinctness. In all its more important features it coincides with the adjoining county of Londonderry. The greater portion of the surface is covered with trap. Along the coast, from a little way to the north of Carrickfergus, and up the valley of the Lagan, there is a considerable line of New Red Sandstone. All along from the south of Lisburn to Red Bay there is a chalk formation coming to the surface in narrow lines. It is quarried in many places, and varies in thickness from a few feet to 170, as at Glenarm. The south side of Red Bay and a part of the north are formed of New Red Sandstone, which gives place to porphyry near Cushendall, and is succeeded by Devonian grit northwards. There is a considerable circle of porphyry about five or six miles north-east of the town of Antrim. The lias (except at Larne) is very insignificant, and the greensand still more so. The coal measures are remarkable for their association with the basaltic formation, and differ from all the other coal districts in Ireland in wanting the underlying limestone, and resting directly on mica slate. The workings at the Ballycastle collieries are probably the oldest in the kingdom. In 1770 the miners accidentally discovered a complete gallery, which had been driven many hundred yards into the bed of coal, branching into thirty-six chambers dressed quite square, and in a workman-like manner. No tradition of the mine having been formerly worked remained in the neighbourhood. The coal of some of the beds is bituminous, and of others anthracite. The quantity available was calculated by the commissioners in 1871 to be 16,000,000 tons, at depths not exceeding 4000 feet. Lignite occurs in great abundance round about Lough Neagh, as at Ballintoy, Limineogh, Killymorris. In most places it is covered with columns of basalt; and in spite of the compressed state in which it is found, the bark and knots are often quite distinct, and the rings of growth may be counted. Basaltic pillars are found in many places besides the famous Giant's Causeway, as round about Coleraine, near Dunluce, at Ballintoy, Ballycastle, Ballygally Head (near Larne), in the neighbourhood of Carrickfergus, at Shane's Castle, and the mouth of the Glenavy. Iron ore is obtained at Ardshins, Belfast, Ballycastle, Glenrava, Kilwaughter, and Shane's Castle—the produce in 1871 being 157,874 tons, of the value of £61,110. Among the other minerals to be met with in Antrim, chalcedony (at Lough Neagh, and known as Lough Neagh pebbles), chrysolite, dolomite, jasper, onyx, opal, and talc may be mentioned. Very fine rock-salt is got at Duncrue, two miles north-west of Carrickfergus, and at one or two places in the same district. The Belfast Salt Mining Company raised during 1871 18,260 tons, and in 1870, 19,450. The mineral (chalybeate) waters of the county are in the neighbourhood of Antrim, Ballycastle, Belfast, Carrickfergus, and Larne.

The chief bathing-places are Ballycastle, Cushendall, Cushendun, Glenarm, Port Ballintrae, and Portrush. They are exposed to the easterly winds prevalent in spring, but are desirable summer residences. There is much variety of scenery in the county, from the low and somewhat monotonous shores of Lough Neagh, and the dreary bog and mountain land of the interior, to the wild romantic scenery of the northern coast, and the fantastically beautiful shores about Glenarm.

The soil varies greatly according to the district, being in some cases a rich loam, in others a chalky marl, and elsewhere a coating of peat. The chief feature in the tillage of a considerable portion of the county is the potato-fallow. The quantity of potato-land is commonly regulated by the amount of manure that can be collected; and since the use of lime was introduced it has been greatly increased. After potatoes, wheat or oats are sown; if the latter, two or three crops are successively taken. When the ground is exhausted potatoes are again planted, or the land is suffered to rest for a year or two until it is covered with natural grass. The sowing of wheat is chiefly confined to the baronies of Massareene, Belfast, Toome, and Antrim. Flax is also sown after potatoes, except in the lower or northern part of the county. The total area under tillage extended in 1871 to 257,211 acres. The crops are wheat, oats, barley, beans and pease, potatoes, turnips, vetches, rape, &c. Considerable quantities of flax are also grown, as well as grasses and clover. The cattle of Antrim do not belong to any particular stock, but they have been greatly improved by crossing with Dutch, Ayrshire, and other breeds. Pigs are reared in considerable numbers, the small farmers and cottars depending chiefly upon them for making up their rent. Comparing recent with previous years, we find an increase in all kinds of domestic animals, especially in sheep and goats—the former having more than doubled, and the latter increased more than fourfold. The farms are usually small. Extensive woodlands have in great measure been cleared, and there is now but little natural wood in the county. Many thriving plantations of trees have, however, been planted near noblemen and gentlemen's seats; and orchards have been formed on the Hertford estate, near Lough Neagh.

Cod, ling, pollock, ray, and turbot are caught off the coast in considerable quantities by the fishermen of Ballycastle, Larne, Carrickfergus, Belfast, &c., most of the fish thus taken being sent to Glasgow and Liverpool. Mackerel also appear in periodical shoals off Larne. Oysters of good quality are taken all over Belfast Lough, of the value of £400 or £500 per annum. Besides the fish usually found in fresh-water lakes, the char, a species of trout called dollagher, and the pullan (or fresh-water herring) are found in Lough Neagh. There are extensive salmon fisheries at Carrick-a-Rede near Ballintoy, along the coast north of Glenarm, and in the rivers Bann and Bush; and salmon are found in all the rivers in the county, except the Lagan. All the rivers abound with eels, which are chiefly taken at weirs in the Bann.

Antrim has long been distinguished for its linen manufacture, which is still the most important in the county. It was formerly carried on by hand-loom weavers, but the introduction of machinery has completely changed the character of the occupation. In 1841 there were about 240,000 spindles in operation, and now there are upwards of 580,000. There were 64 flax factories in 1870, with 9140 power-looms, employing 32,487. Cotton-spinning by jennies was first introduced in 1777 by Robert Joy and Thomas M'Cabe of Belfast; and twenty-three years after upwards of 27,000 people were employed in the cotton manufacture directly or indirectly, within 10 miles of Belfast. For many years great part of the yarn was imported from Manchester or Scotland, but now cotton-yarn has long been an article of exportation. In 1870 there were six cotton factories, with 73,000 spinning-spindles, in Belfast, and employing 814 persons. There is one hemp, and one jute factory in the county. A great source of employment for females is the working of patterns on muslin with the needle. Belfast is the centre of this trade, but about 300,000 persons, chiefly women, are employed in various parts of Ireland, and the gross value of the manufactured goods amounts to about £1,400,000. There are also extensive paper-mills in the county, and various manufactures in connection with the trade of the district. The exports are linen, linen yarn, all kinds of grain, pork, bacon, hams, beef, butter, eggs, lard, potatoes, soap, and candles.

The communication by means of roads is good, and there are several important railway lines. About 20 miles of the Ulster Railway, which runs from Belfast to Clones in Monaghan, are in the county. Another line joins Belfast with Carrickfergus and Larne; and the Belfast and Northern Counties Railway—using a portion of the Carrickfergus line—unites Belfast with Antrim, Ballymena, Ballymoney, and Coleraine in Londonderry, &c. A junction, 18½ miles long, from Antrim to Knockmore, joins this line with the Ulster Railway. There are regular steam-ship lines between Belfast and Glasgow, and Belfast and London. A canal—the Lagan—connects Lough Neagh with Belfast Lough.

The earliest known inhabitants were of Celtic origin, and the names of the townlands or subdivisions, supposed to have been made in the 13th century, are pure Celtic. Antrim was exposed to the inroads of the Danes, and also of the northern Scots, who ultimately effected permanent settlements. The antiquities of the county consist of cairns, mounts or forts, remains of ecclesiastical and military structures, and round towers. The principal cairns are—one on Colin mountain, near Lisburn; one on Slieve True, near Carrickfergus; and two on Colinward. The cromlechs most worthy of notice are—one near Cairngrainey, to the north-east of the old road from Belfast to Templepatrick; the large cromlech at Mount Druid, near Ballintoy; and one at the northern extremity of Island Magee. The mounts, forts, and intrenchments are very numerous. There are four round towers: one at Antrim, one at Armoy, one on Ram island in Lough Neagh, and a fragment of one between Lisburn and Moira. Of the ecclesiastical establishments enumerated by Archdall, there are some remains of those of Bonamargy, where the earls of Antrim are buried, Kells, Glenarm, Glynn, Muckamore, and White Abbey. The noble castle of Carrickfergus is the only one in perfect preservation. There are, however, remains of other ancient castles, as Olderfleet, Carn's, Shane's, Glenarm, Garron Tower, Redbay, &c., but the most interesting of all is the castle of Dunluce, remarkable for its great extent and romantic situation.

In 1584 the county was divided by the lord-deputy, Sir John Perrot, into eight baronies; but, by the subdivision of six of these into upper and lower, the number has been increased to fourteen, viz., Antrim, Lower and Upper; Belfast, Lower and Upper; Cary; Dunluce, Lower and Upper; Glenarm, Lower and Upper; Kilconway; Massareene, Lower and Upper; Toome, Lower and Upper. The number of parishes and parts of parishes is seventy-five, all, except Aghalee, in the diocese of Connor. There are seven poor-law unions in the county,—Antrim, Ballycastle, Ballymena, Ballymoney (partly in Londonderry county), Lisburn (partly in Down county), and Larne. The constabulary force has its headquarters at Ballymena, the county being divided into six districts. Antrim is in the Belfast military district, which has its headquarters, as has also the county militia, at Belfast. The valuation of rateable property in 1872 was £1,039,898. The county sends six members to the imperial parliament: two for the shire, —constituency, in 1873, 10,563; two for Belfast, one for Carrickfergus, and one for Lisburn,—constituencies, 15,000, 1166, and 568. Among the nobility and gentry who have estates in this county we may mention the earl of Antrim, (Glenarm Castle); the marquis of Donegall (Ormeau Park and Carrickfergus); Viscount Templetown (Castle Upton); Lord O'Neill (Shane's Castle); Lord Waveney (Ballymena

Castle); Sir Richard Wallace (Antrim Castle); Macnaughten of Dundarave; Adair of Loughanmore, &c.

The assizes, formerly held at Carrickfergus, are now held at Belfast, the county town. Quarter-sessions are held at Antrim, Ballymena, Ballymoney, and Belfast.

The principal towns are—Belfast, population (1871), 174,394; Carrickfergus, 9452; Lisburn, 7794; Ballymena, 7628; and Larne, 3343. Antrim, Ballycastle, Ballymena, Ballymoney, Belfast, Bushmills, Carrickfergus, Crumlin, Larne, Lisburn, Portglenone, and Randalstown are market-towns, and fairs are held at forty-eight places in the county.

Antrim is one of the most decidedly Protestant counties in Ireland, and of the Protestants a very great proportion are Presbyterians. The greater part of these are in connection with the General Synod of Ulster, and the others are Remonstrants, who separated from the synod in 1829, or United Presbyterians. By the returns of 1871 there were 108,835 Roman Catholics, 88,934 Episcopalians, and 184,144 Presbyterians. The number of children attending school in 1871 was 142,297, of whom 34,637 were Roman Catholics.

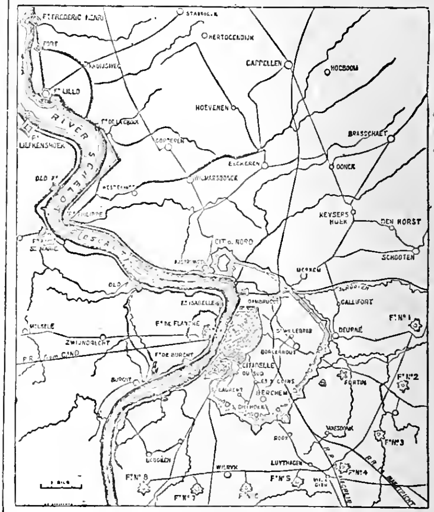
In 1813 there were in the county 42,258 dwelling-houses and 231,548 inhabitants. The returns since that year have shown a gradual increase, notwithstanding extensive emigration, and in 1871 the population was 404,015, inhabiting 71,327 houses.

See for geology, *Proceedings of Royal Irish Academy*, vol. x., article, with map, by John Kelly, C.E., and article by R. Tate, in the 21st vol. of the *Quarterly Journal of Geol. Soc. of London*, 1868; and for archæology, *The Ulster Journal of Archæology*, vols. iii. and iv., and Keane's *Towers and Temples of Ireland*.

ANTRIM, a town of Ireland, in the county noticed above, half a mile from Lough Neagh, on the banks of the Six-mile Water, in a fertile and beautiful valley, 13 miles north-west of Belfast, and 106 north of Dublin. It gives the title of earl to the family of MacDonnell, and prior to the Union returned two members to parliament by virtue of letters patent, granted to the inhabitants in 1666 by Charles II. There is nothing in the town particularly worthy of notice; but the environs, including Shane's Castle and the grounds of Massareene Castle, possess considerable interest. About a mile from the town is one of the most perfect of the round towers of Ireland, 95 feet high, and 49 in circumference at the base. Markets are held each Tuesday and Thursday, and fairs on January 1, May 12, and November 12. In 1871 the town contained 427 dwelling-houses, and 2020 inhabitants. The receipts by the town commissioners were £120 in 1872, and their expenditure £127. The manufacture of paper has been carried on here on a small scale for many years, and linen and woollen cloth is also produced in moderate quantity. The Belfast and Northern Counties Railway passes a short distance to the north of the town. A battle was fought near Antrim, between the English and Irish, in the reign of Edward III.; and on June 7, 1798, there was a smart action in the town between the king's troops and a large body of rebels, in which the latter were defeated, and Lord O'Neill mortally wounded.

ANTWERP (Dutch, *Antwerpen;* French, *Anvers;* Spanish, *Amberes;* Old German, *Antorff;* from "aent werf," "on the wharf"), a province of Belgium, bounded by the Dutch province of North Brabant on the N., and by the Belgian provinces of Limbourg on the E., South Brabant on the S., and East Flanders on the W. The greater part of the province, which consists of an extensive plain of 1096 square miles, scarcely diversified by a single elevation, is sandy but fertile, producing grain, flax, hemp, fruit, and tobacco, as well as cattle, sheep, and horses; on the north and north-east, however, there are considerable tracts of morass and heath. The principal rivers, the Scheldt and its tributaries, the Rupel, the Nèthe, and the Dyle, are navigable to a large extent, while railways intersect the country in various directions and there are also several canals. The chief towns are Antwerp, Mechlin (Malines), Turnhout, Lierre, and Boom. Population in 1870, 492,482.

ANTWERP, the capital of the province of the same name, is situated about 50 miles from the open sea and



Plan of Antwerp and Environs.

25 north of Brussels, in a level tract on the right bank of the Scheldt, which is there about 2200 feet broad, and has a depth at ebb-tide of from 30 to 40 feet, with a rise at spring-tides of 12 or 14. Antwerp seems to have been founded by people of Saxon race some time before the 8th century, when the Antwerpians or Ganerbians, as they began to be called, were converted to Christianity by St Willebrod and some Irish monks. A certain Rohingus of that period styles himself prince of Antwerp; and mention is made of a market-toll in force in 726. In 837 the town fell into the hands of the Northmen, who kept possession of it for about sixty years. It was erected into a marquisate of the Holy Roman empire by Henry II. in 1008, and, as such, was bestowed by Henry IV., in 1076, on Godfrey of Bouillon. About the beginning of the 12th century it had considerable commercial prosperity; and in the 13th, its municipal institutions took definite shape. It is worthy of notice that the law of 1290 contained provisions identical with those of the Habeas Corpus Act in England, maintaining the inviolability of the citizen's dwelling, and acknowledging the right of every man to be judged by his peers, and to have a voice in the imposition of taxes. As the result of such security and freedom, the commerce of the city rapidly increased. The English wools for the great manufactories at Louvain, Brussels, Tirlemont, Diest, and Lean, were imported through Antwerp; and the English merchants, who formed a "factory" there in 1296, received special protection by charters (1305, 1341, 1346, 1349) from the

Dukes of Brabant, at that time in possession of the marquisate. In 1338, while Edward III. of England was spending the winter in the city with his queen Philippa, she gave birth to Lionel, afterwards Duke of Clarence, and the event was celebrated by a magnificent tournament. To the king, then in great need of money, the merchants of Antwerp advanced 400,000 florins. The marquisate passed successively into the hands of the counts of Flanders and the house of Burgundy, and returned to Brabant about 1406. In 1474 the town made over a large house in Billinck Street to the English, in 1550 an "English Bourse" was established, and in 1558 the beautiful Hop van Lyere—now a military hospital—was ceded for the accommodation of our merchants. Between 1488 and 1570 was the time of the greatest prosperity which Antwerp was destined to attain for several centuries. The discovery of America in 1492, and of the passage to India in 1497, produced a great change in all European navigation, and permanently altered the old courses of commerce. While, in consequence of this, the cities of the Hanseatic League had withered, and Venice, and Nuremberg, and Bruges were sinking into decay, Antwerp was growing daily more worthy of the name which she soon acquired, "*Dives Antwerpia*," "the wealthy Antwerp." By contemporaneous writers, such as Guicciardini and Scribanius, the most glowing accounts have been left of her greatness. The annual fairs of Pentecost and St Badon's—which have now no commercial importance—attracted merchants from all parts of Europe. No fewer than 500 ships would enter the port in a day, and as many as 2500 were to be seen lying in the river at one time. On an average 500 waggons laden with goods daily entered the gates; above 500,000,000 guilders were annually put in circulation; and the population is said to have numbered upwards of 100,000. But from this height of prosperity the city was suddenly cast down by the wars of the 16th century. In 1576 it was taken by the Spaniards, and given up to a three days' pillage; it was besieged, though in vain, by the duke of Alençon in 1583; and, after a very obstinate defence, it fell before the assaults of the duke of Parma, whose triumphal entry took place on the 17th of August 1585. Its glory departed; its commerce was ruined; its inhabitants were scattered. As the people of Bruges had flocked to Antwerp, so now the people of Antwerp flocked to Hamburg. The Dutch, in their jealousy, endeavoured to complete its ruin by building forts on the river to intercept the passage of ships; and finally, by the peace of Westphalia, in 1648, the Scheldt was definitively closed. In 1794 the city fell into the hands of the French, who opened the river and made Antwerp the capital of the department of Deux Nèthes. Napoleon, who visited the place in 1803, attempted to make it a great military and commercial centre, and spent no less than £2,000,000 sterling in the construction of docks. He was wont to speak of it as *un pistolet chargé que je tiens sur la gorge de l'Angleterre.* It continued in French possession till 1814, when it was surrendered after the treaty of Paris by Carnot, who up to that time had defended it with great bravery against the allied army under Graham. From 1815 to 1830, Antwerp with the rest of Belgium united with Holland in forming the kingdom of the Netherlands. In 1830, during the Belgian revolution, the citadel was held by the old Dutch general Chassé, who resolutely refused to surrender. At length, however, in 1832 he was forced to capitulate by the French, under Marshal Gérard, and the city was handed over to the Belgians. All matters of dispute between Belgium and Holland being finally settled by the treaty of 1839, Antwerp has continued peacefully to advance in prosperity ever since. In 1860 the ancient fortifications were destroyed, and new fortifications erected at a considerable distance from the city; while a line of detached forts were built towards the south-east, in an arc of a circle, which it has been proposed to complete on both sides of the river. The famous "citadel of the south," which was originally built by the duke of Alva in 1567, has been bought from the Belgian Government by the *Société Immobilière* and the town of Antwerp, and the site is to be appropriated for new docks and a new quarter of the city—the docks to be for the accommodation of river-boats and lighters. A loan of 60,000,000 francs (£250,000) is to be contracted for the carrying out of the improvements. Since the destruction of the old fortifications, fine boulevards, avenues, and streets have been laid out, and the town is rapidly and constantly increasing in size. There are now seventeen quays or wharves, and a series of 6 or 8 docks communicating with each other. The two oldest, which were constructed under Napoleon, and preserved when his other establishments were destroyed, are respectively about 574 feet by 492, and 1312 by 574. Since Napoleon's time the city has added the *Bassin de Jonction*, the large *Kattendyk Dock* (opened in 1856), the *Bassin Sas*, the *Bassin aux Bois*, or timber-dock, the *Bassin de la Campine*, and the *Bassin du Canal*. The whole system has an area of nearly 100 acres, affording over 21,000 feet of quay-room. In spite of all this extension of accommodation, the commercial traffic is so great that ships are often delayed through lack of sufficient room for lading or unlading. In 1826, 909 vessels entered with a tonnage of 122,221, of which 126 were British, with a tonnage of 16,178; in 1862 the number of vessels was 2292, with a total tonnage of 579,899, of which 777 were British, with a tonnage of 199,000; and by 1872 the vessels amounted to 4206, and had a tonnage of 1,656,984, 2172 of them being British, and having a tonnage of 1,007,165. Of the British traffic, a very large proportion is carried on by means of steam-ships. The chief imports are steel, copper, iron, and other metals, machinery, coals (chiefly from Britain), salt, soda, grain, cotton (chiefly from New Orleans and Bombay), cotton yarn and goods, wool (mostly undressed), hides (raw and tanned), sugar (chiefly raw), tea, coffee, tobacco, rice, and oil-seeds. The chief exports are flax, woollen goods, refined sugar, metals, glass, and tallow. There is regular steam communication with London, Hull, Liverpool, and other English ports, and, indeed, with all the most important ports in Europe. There are also regular lines to the United States, Brazil, La Plata, and Chili. By the river and several canals there is communication with most of the other Belgian cities. The "*Canal de la Campine*" is the most important, and joins the Scheldt with the Meuse, through the Willem Canal, which was made by the Dutch Government. The railway system with which Antwerp is connected is extensive, but is far from sufficient to satisfy the demands of trade. The manufactures of Antwerp are various and considerable, the principal being lace, silk, linen, jute, cotton, tapestry, galloon, twine, sugar, white-lead, litmus, starch, printer's ink, and malt liquors. There are about 20 sugar refineries, 7 rice-mills, 3 sulphur refineries, several cigar manufactories, distilleries, petroleum refineries, stearine candle manufactories, and wool-mills. The lapidaries of Antwerp are celebrated for their skill in cutting diamonds.

The National Bank of Belgium has a branch in the city, and several other banks transact extensive business. The Exchange, built in 1531, was one of the finest buildings of the kind in Europe, and is said to have been chosen by Sir Thomas Gresham as a model for the old Royal Exchange in London. Burnt down in 1858, it was rebuilt in the same Gothic style as before, and opened again for business in 1872. The old magazine of the Hanseatic League (1564), known as the *Maison Hanseatique*, still stands a "massive and venerable" building. The cathedral of Notre Dame, probably founded about the middle of the

14th century, but not completed till 1518, is one of the most beautiful specimens of Gothic architecture in Belgium. It is about 500 feet long and 250 broad, and is the only church in Europe with six aisles. Of its two projected towers, the one rises to a height of 403 feet, the other remains unfinished. It contains, besides other remarkable pictures, Rubens's "Descent from the Cross," his "Elevation of the Cross," and his "Assumption." The cathedral, however, is greatly surpassed in the splendour of its decorations and the profusion of its monuments by the church of St James (15th century), which contains, in addition to other mortuary chapels and shrines, the family-chapel and tomb of Rubens, with a beautiful altar-piece, the workmanship of the great painter. The high altar of the church was also designed by Rubens. Of the remaining churches, the most important are St Paul's, St Andrew's, and the church of the Augustines. The church that formerly belonged to the Corporation of Tanners is now the Anglican place of worship. The *Hôtel de Ville* is a fine building in the Italian style, with a facade that exhibits four orders of architecture, one above the other; but within, there is not much to attract attention. Antwerp possesses an Athenæum, in which most of the usual branches of literature and science are taught; an academy of the fine arts, where the students receive instruction in painting, sculpture, architecture, and engraving; a "*Museum*" or Gallery of over 560 pictures, including some very fine specimens of Rubens, Vandyck, Titian, Teniers, Jordaens, Quintin Matsys, and other masters; a medical and surgical college; a school of navigation; zoological and botanical gardens; a theatre; and various scientific and literary societies. The town library contains 30,000 volumes. The library of the famous printer, Plantin, his workshop, presses, and printing materials, as left by the Moretus family who succeeded him, and a fine collection of paintings, drawings, manuscripts, &c., were purchased by the town for about a million and a half of francs (£62,500), and form an interesting typographic museum.

Antwerp is the birth-place of a number of distinguished men in various departments, as the painters Vandyck (b. 1599), Teniers the elder (1582), Teniers the younger (1610), Jordaens (1594), Frans Floris (1520), Gonzales Cocques (1618); the philologist Gruter (1560), the geographer Ortelius (1527), the engraver Edelinck (1649), and, among more modern celebrities, Van Meteren the historian, Ogier the dramatist, and Henri Conscience the novelist. Rubens was born at Cologne, but his family belonged to Antwerp, and he was educated, resided, and died in the latter city.

According to the general census of 1846, Antwerp contained 88,487 inhabitants, of whom 85,961 were Roman Catholics, and 1312 Protestants. In 1851 the population was 95,501, and in 1873, 126,663, or, including the suburbs now situated within the fortifications, above 180,000. The majority of the inhabitants speak Dutch or Flemish, and the rest, for the most part, French or Walloon.

Scribanii *Origines Antwerpiensium;* Gens, *Histoire de la Ville d'Anvers;* Mertens and Torfs, *Geschiedenis van Antwerp;* Bruyssel, *Histoire du Commerce, etc., de Belgique; Consular Reports on British Trade Abroad*, 1873, pp. 517–555; Motley's *Rise of the Dutch Republic.*

ANUBIS, an Egyptian deity, called in hieroglyphs *Anepu* or *Anup*, and in Coptic, *Anob* or *Anoub*. It appears from the hieroglyphic legends that he was the son of Osiris and Isis, not Nephthys, as stated by Plutarch. His name has no particular meaning in hieroglyphs, although it resembles the Coptic *anebe*, the appellation of a particular kind of dog. His worship was of the oldest period, and is found in tombs at Memphis, of the age of the 4th dynasty, at which period all dedications run in his name instead of that of Osiris, which did not appear till the 6th. At this time he is always styled resident in the sacred abode, and attached to the land of Ut, and lord of the Taser or Hades. At the earliest period he presided over the funeral rites and embalming of the dead, on account of having rendered these offices to his father Osiris. In this character he is seen raising the mummy on its feet to receive the sepulchral sacrifices and libations, or else laying it out on the bier, to which the soul flies down to visit or be reunited to the body. In the great judgment Anubis, with Thoth, attends to the balance placed in the Hall of the Two Truths, where the soul is tried by Osiris as judge of Hades, and the heart of the dead is weighed against the feather of Truth. Besides his sepulchral character, Anubis was also called *Ap-heru*, "opener of the roads" or "paths," which were supposed to lead to heaven. Of these there were two, the "northern and the southern." As lord of the northern road he was lord of Sais, while as ruling the southern, he was lord of Taser or Hades. In this character he was often represented as a jackal seated on a pylon or gateway, the jackal being his sacred animal or living emblem. This may be considered the type of the celestial Anubis, and as such he was styled lord of the heaven, and opener of the solar disk. Anubis is represented with the head of a jackal, seldom with that of a man, and rarely with any head attire, although at the Roman period his head is surmounted by the pschent, or crown of Upper and Lower Egypt. In other respects his type is that of other Egyptian deities. In the tablets and other monuments of the 18th and later dynasties, Anubis is introduced as following, or as part of, the cortege of Osiris; sometimes he is worshipped alone; but he was a subordinate god of the third order, supposed to have reigned over Egypt as one of the kings of the 2d dynasty of gods. The principal site of his local worship was Lycopolis, or El Siut, the capital of the 13th and 14th (or Lycopolite) nomes, and at the 17th or Cynopolite nome; but he appears also as one of the gods of the 18th or Oxyrhynchite nome, and as such is styled lord of *Sep*. In this character he is said to have defeated the opposers of his father Osiris, which accords with the story of Diodorus, that Anubis was the general of Osiris in his Eastern expedition. The introduction of Anubis into the Isiac worship about the 1st century B.C., gave rise to various esoterical explanations not found in the hieroglyphs. He is stated to have been the son of Nephthys and Osiris, and discovered by dogs, and hence had a dog's or jackal's head; also that he represented the horizontal circle which divides the invisible world, called by the Egyptians Nephthys, in contradistinction to Isis, or the visible, or to have been like Hecate. He was also supposed to mean time and universal reason. But these explanations are not found in the hieroglyphs, and the change of his head to that of a dog instead of a jackal, was not Egyptian. On Roman monuments of the 1st and 2d century A.D., his form is combined with that of Hermes, and passed by the name of Hermanubis, in his character of the infernal Mercury. In the days of Tiberius, the seduction of a noble Roman lady in his temple at Rome, with the connivance of the priests, led to the suppression of his worship, but at a later period the Emperor Commodus, infatuated with the Isiac worship, shaved his head like an Egyptian priest, and carried in procession the figure of the god. The idea that his name meant gold, as suggested by the learned, is confuted by the hieroglyphs; nor are the statues found of him either gold or gilded, while in the Egyptian paintings he is always coloured *black*, and never yellow or golden, as the goddesses often are. The jackal was his sacred living animal, and was embalmed after death, and this animal represented, according to Clement of Alexandria, either the two hemispheres which environed the terrestrial globe, or the tropics. Figures of Anubis in porcelain are not uncommon in Egyptian collections, having been attached to the outer network of bugles which covered the mummies, but in other materials they are much rarer. The jackal, his animal and emblem, is, however, often placed on chests, or other sepulchral monuments. His worship commenced at the earliest period of Egyptian history, and continued, in one form or another, till Egyptian paganism was superseded by Christianity. He was, in fact, one of the oldest, if not the oldest deity of the paganism of the world. (Wilkinson, *Mann. and Cust.* vol. iii. p. 440, *ff.*; Birch, *Gallery of Antiquities*, p. 43; Bunsen, *Egypt's Place*, vol. i. 2d ed. p. 240; Plutarch, *De Iside*, c. 14; Josephus, *Ant.* xviii. c. 6; Brugsch, *Die Geographie des alten Ægyptens*, i. taf. 23, 25; Jablonsky, *Panth. Ægypt.* iii. p. 3, *ff.*) (S. B.)

ANVIL, an iron block, with a smooth flat steel face, on which the malleable metals are hammered and shaped. They are of all sizes, from the tiny anvils used by the watchmaker to the ponderous masses employed in the arsenal of Woolwich. The common blacksmith's anvil is built up of six pieces welded to a central core, viz., four corner pieces, a projecting end, with a square hole for the reception of a chisel with its edge uppermost, and a conical end for hammering curved pieces of metal. These six pieces are first roughly welded to the core, and the whole is then thoroughly hammered and suitably shaped. A thin facing of steel is next welded on and carefully tempered; the surface of this is then ground perfectly flat, and, if need be, polished.

ANWARI, one of the earlier Persian poets, was born in Khorassan, in the 12th century. He enjoyed the especial favour of the Sultan Sandjar, whom he attended in all his warlike expeditions. On one occasion, when the sultan was besieging the fortress of Hazarasp, a fierce poetical conflict was maintained between Anwari and his rival Rasheedi, who was within the beleaguered castle, by means of verses fastened to arrows. Anwari died at Balkh about 1200. *The Diwan*, or collection of his poems, consists of a series of long poems, and a number of simpler lyrics. His longest piece, *The Tears of Khorassan*, translated into English verse by Captain Kirkpatrick, appeared in the *Asiatic Miscellany*.

ANWEILER, or ANNWEILER, a town of Bavaria, in the Rhine Palatinate, situated on the Queich, 8 miles W. of Landau, containing 2734 inhabitants, who are chiefly employed in cloth weaving, brushmaking, tanning, and dyeing. Near it is the castle of Trifels, in which Richard Cœur de Lion was imprisoned in 1193.

ANXENOR, a Greek sculptor, a native of Naxus, known only from the inscription on a sepulchral relief in Orchomenus, of which he was the author. From the style of the sculpture, and the form of the letters, it is inferred that he had lived in the early part of the 5th century B.C.

ANZIN, a town of France, in the department of Nord, situated on the Escaut (Scheldt), not far from Valenciennes, in the centre of the most valuable coal-mining district in France, a large part of which takes its name from the town, and gives employment to about 6000 persons. Anzin also possesses iron foundries, glass-works, breweries, and distilleries of considerable value. Population, 7283.

AOSTA, a town of the kingdom of Italy, the capital of a circle of the same name in the province of Turin, situated on the Dora Baltea, at the point where the roads over Great and Little St Bernard meet, 49 miles N. of Turin. It is a tolerably well-built place, containing a cathedral, and a fine town hall, as well as a triumphal arch, an amphitheatre, and other Roman remains. The inhabitants, who number 7669, carry on a considerable trade in wine, cheese, leather, and hemp. Aosta, the ancient *Augusta Prætoria*, celebrated as the birth-place of Anselm, archbishop of Canterbury, was formerly the capital of a duchy of the same name in Piedmont, which eventually became a province of Sardinia, and was merged in the Italian province of Turin in 1861. The Val d'Aosta, which formed the greater part of Aosta province, produces large quantities of grain, fruit, and cattle, while the mountains abound in iron and other minerals. Cretinism prevails extensively among the inhabitants.

APAMEA, in *Ancient Geography*, the name of several Asiatic cities:—1. A large city of Syria, in the valley of the Orontes, so named by Seleucus Nicator, after Apama, his wife. It continued to be a place of importance down to the time of the Crusades, when it was known as *Fâmieh*, and is supposed to be represented by the extensive ruins at Kulat-el-Mudyk. 2. A large commercial city in Phrygia, which owed its existence to Antiochus Soter, and its name to his mother, Apama. It is identified with the modern *Denair*, where there are still a number of ancient ruins. 3. A city mentioned by Stephanus and Pliny as situated near the Tigris, the identification of which is still uncertain. 4. Now *Rum-Kala*, on the left of the Euphrates, opposite Zeugma. 5. The name given to Myrlea of Bithynia, by Prusias I., who rebuilt it. The ruins lie near Medania. 6. A Greek city in Parthia, near Rhagæ.

APANAGE (*apanagium*, probably from *panis*, bread), the provision in the form of lands or feudal superiorities made for younger sons by the kings of France. The custom of bestowing apanages was first established under the dynasty of the Capets; the rule at an earlier period being that the kingdom should be divided as equally as possible among all the members of the family on the death of the sovereign. Hallam (*Middle Ages*, c. i. part 2) points out how the possession of apanages made the princes of the blood royal "a distinct and formidable class of men." They were generally opposed to the sovereign, and the sovereign on his part endeavoured to check their power as much as possible. From the time of Louis VIII. apanages were held subject to the condition that they should revert to the crown on the extinction of heirs-male. (See Pasquier's *Recherches*, ii. 18; Henault's *Histoire de France*, anno 1283.) In England, where apanage is not a legal term, the word is used popularly in a variety of cognate senses.

APATIN, a town of Hungary, situated on the left bank of the Danube, 125 miles S. of Pesth. It has manufactures of woollen cloth and silk, dye-works, and a considerable trade in raw silk, hemp, madder, and woad. Population, 11,047.

APATURIA (Ἀπατούρια), a Greek festival held annually by all the Ionian towns except Ephesus and Colophon, the reason assigned for their exception being some suspicion of a murder (*Herod.*, i. 147). But, unless at Athens, little is known of the manner in which it was conducted. There it fell in the month of *Pyanepsion*, corresponding nearly to our November, and lasted three days, the occasion being one on which the various *phratriæ*, or clans of Attica, met to arrange matters proper to each, and hence the name has been traced to a form, ἀπατόρια, in the sense of ἁμαπατόρια, or ὁμοπατόρια, meaning "a ceremony for the assertion of relationship." According to the popular derivation, however, the festival originated 1100 B.C., to commemorate an encounter between the Athenians and Bœotians, in which the king of Attica, Thymœtes, having been challenged to single combat by the Bœotian king, Xanthius or Xanthus, and, being afraid to meet him, accepted as a substitute Melanthus, an exile, with the condition of his succeeding if victorious, to the throne of Attica. When the combatants met, Melanthus, to throw his adversary off his guard, declared that he was being unfairly assisted by a man wearing a black goat's skin. Xanthus turned to look, and while in the act was struck down. This deceit, ἀπάτη, was the origin of the festival! The man in the black goat's skin was believed to have been Dionysus (Bacchus) Melanaigis. On the first day of the festival, called *Dorpia* or *Dorpeia*, banquets were held towards evening. On the second, *Anarrhysis*, a sacrifice of oxen was offered at the public cost. On the third day, κουρεῶτις, children born since the last festival were presented by their fathers or guardians to the assembled *phratores*, and, after an oath had been taken as to their legitimacy, and the sacrifice of a goat or a sheep offered, their names were inscribed in the registers. On this day also it was the custom for boys still at school to declaim pieces of poetry, and to receive prizes. (A. S. M.)

APE

APE (*aap;* Dutch; *Affe*, German; *Affo*, Old German; *apa*, Swedish and Irish; *epa*, Welsh), a word of uncertain, and not improbably African origin, and by some supposed to have originated in an imitation of the animal's "chatter."

The zoological group denoted by the term "ape," when used in its widest sense, includes animals known by the familiar terms of "monkeys" and "baboons," as well as others bearing the less known names of "sapajous," "sakis," and "marmosets." In a more restricted sense the term "ape" is sometimes emphatically applied to those of the whole group which are most man-like in structure, namely, to the orang, the chimpanzee, the gorilla, and the gibbons.

Certain other animals, of very different structure, are generally associated in the same ordinal group with the apes. These other animals are the lemurs, or lemuroids; called also "half-apes," after their German designation of *Halbaffen*.

By Linnæus these creatures, together with bats and man, were placed in his highest and first order, to which he gave the name "*Primates*," dividing its contents into the four genera, *Homo*, *Simia*, *Lemur*, and *Vespertilio*. The bats are now by universal consent removed from the order; and some eminent naturalists, notably Professor Alphonse Milne-Edwards, are disposed to remove from it the lemurs also; but in every case there can be no question but that the latter animals must at least rank as a *sub-order*, for which the term "*Lemuroidea*" has been proposed.[1]

The question whether man should or should not be placed in the same zoological order with the apes, must be decided according to the principles of classification adopted. If that classification be purely morphological, *i.e.*, be determined by form and structure only, he cannot well be separated from them, at least by any naturalist who would also include the lemurs in such order. The Linnean name "*Primates*" has been retained for the ape order, not only by naturalists who (like Professor Huxley) retain man within its limits; but also by others (*e.g.*, the Professors Isidore Geoffroy St Hilaire and Gervais), who consider that he should be excluded from it. Cuvier, on the other hand, proposed for the ordinal group of apes and lemurs only the term *Quadrumanes* (or four-handed), giving to that order, within which he placed man alone, the antithetical term *Bimanes*. In this he has been followed by very many naturalists, and in England, amongst others, by Professor Owen; and, perhaps, the majority of writers since Cuvier have bestowed on two distinct *orders* the names *Quadrumana* and *Bimana* respectively.

Priority of use determines our preference for the Linnean name "*Primates*," but this preference is reinforced by considerations derived from anatomy and physiology.

The whole of the apes, as indeed the whole of the half-apes also, differ from man in having the great toe, or (as it is called in anatomy) the *hallux*, so constructed as to be able to oppose the other toes (much as our thumb can oppose the fingers), instead of being parallel with the other toes, and exclusively adapted for supporting the body on the ground. The prehensile character of the hallux is fully maintained even in those forms which, like the baboons, are terrestrial rather than arboreal in their habits, and are quite quadrupedal in their mode of progression. It was this circumstance that led Cuvier to bestow the name *Quadrumanes* upon the apes and lemurs. Now, if we accept, with Professor Owen, as the definition of the word "foot," "*an extremity in which the hallux forms the fulcrum in standing or walking*," then man alone has a pair of feet. But, anatomically, the foot of apes (as well as that of half-apes) agrees far more with the foot of man than with his hand, and similarly the ape's hand resembles man's hand and differs from his foot. Even estimated physiologically, or according to use and employment, the hand throughout the whole order remains the *special* prehensile organ; while the predominant function of the foot, however prehensile it be, is constantly locomotive. Therefore the term *Quadrumana* is apt to be misleading, since, anatomically as well as physiologically, both apes and men have two hands and a pair of feet.[2]

Apart then from man, the apes constitute the first sub-order of that which is the most man-like order of the class *Mammalia* (beasts), and which bears the name "*Primates*."

Such being the position of apes as a whole, they are zootomically divisible into a number of more and more subordinate groups, termed respectively *families*, *sub-families*, and *genera*.

The following table exhibits what is believed to be, on the whole, the most natural and convenient arrangement of these groups of apes :—

Family I. SIMIADÆ. Sub-Families.	1. *Simiinæ*,	Simia. Troglodytes. Hylobates.
	2. *Semnopithecinæ*,	Semnopithecus. Colobus.
	3. *Cynopithecinæ*,	Cercopithecus. Macacus. Cynocephalus.
Family II. CEBIDÆ. Sub-Families.	1. *Cebinæ*,	Ateles. Eriodes. Lagothrix. Cebus.
	2. *Mycetinæ*,	Mycetes.
	3. *Pitheciinæ*,	Pithecia. Brachyurus.
	4. *Nyctipithecinæ*,	Nyctipithecus. Chrysothrix. Callithrix.
	5. *Hapalinæ*,	Hapale. Midas.

The limits of the present article exclude altogether from consideration the half-apes or *Lemurs*.

The whole of the apes may be characterised by the following zoological definition, the meaning of the terms of which will be explained later :—

[1] See *Proceedings of the Zoological Society* for 1864, p. 635.

[2] See further on this subject, *Philosophical Transactions* for 1867, p. 362.

Unguiculate, claviculate mammals, with a deciduate, discoidal placenta and small allantois; with orbits encircled by and separated off from the temporal fossæ by plates of bone; lachrymal foramen not opening on the cheek; posterior cornua of os hyoides longer than the anterior cornua; dental formula as in man, save that a true molar may be wanting, or that there may be a premolar in excess, or both; brain with well-developed posterior cornua and with the cerebellum quite covered by the cerebrum, or only very slightly uncovered; hallux opposable, with a flat nail or none; a well-developed cæcum; penis pendulous; testes scrotal; only two mammæ, which two are pectoral; uterus not two horned; thumb sometimes rudimentary or absent.

The great group of apes thus characterised is divisible, as the foregoing table indicates, into two great families, which are sharply distinguished by geographical distribution as well as by structural differences. The first of these families, SIMIADÆ, is strictly confined to the warmer latitudes of the Old World. The second family, CEBIDÆ, is as strictly confined to those of the New World.

Of the three sub-families into which the Simiadæ are divided, the first, SIMIINÆ, contains only the orang, the chimpanzee, the gorilla, and the gibbons. These are the creatures which, anatomically, are the most like man of all the apes, on which account they are often called the "anthropoid" apes. They are also termed, on account of the relative breadth of their breast-bone or sternum, the "latisternal" or "broad breast-boned" apes.

The orang (*S. satyrus*) constitutes the genus *Simia*, which gives its name to the whole family (*Simiadæ*), as well as to the sub-family (*Simiinæ*) to which it belongs. Of this genus there is but one certain species, which is, however, subject to considerable variation. The orang is exclusively confined to the islands of Borneo and Sumatra, where it frequents the swampy forests near the coast. It attains a

FIG. 1.—The Orang-outan (*Simia satyrus*). From Mr Wolf's sketch at Zoological Gardens.

height of about 4 feet 4 inches; but its bulk is considerable, its legs, however, being exceedingly short. Its arms, on the contrary, are exceedingly long, reaching down to the ankle when the animal is placed in an erect posture. In harmony with this structure the animal rarely assumes, naturally, a truly erect posture, but walks resting on the knuckles of its hands and the outer sides of its feet, the soles of the latter being turned mainly inwards. Its motions are ordinarily very slow and deliberate, and its demeanour in captivity is languid and melancholy. It is, in a wild state, exclusively a vegetable feeder, and arboreal in its habits, forming in the trees a sort of nest or shelter of interwoven branches. The animal is covered with long, reddish-brown hair, and there are no naked spaces on the hinder part of the trunk. The forehead is rounded and rather high. Adult males are furnished with a longish beard on the chin, and they may also develop a large warty prominence, consisting of fibro-cellular tissue, on each side of the face. There is no vestige of a tail. The hands are very long; but the thumb is short, not reaching to the end of the metacarpal bone of the adjacent (*index*) digit. The feet have exceedingly long toes, except the great toe (*hallux*), which only reaches to the middle of the proximal phalanx of the index digit of the foot. The hallux is often destitute not only of a nail, but of the second or distal phalanx also; it nevertheless possesses an *opponens* muscle. The orang has twelve pairs of ribs, and has, compared with man, an extra wrist bone, or an *os intermedium* in its carpus. The brain of the orang has the cerebrum greatly convoluted, and is altogether more like the brain of man than is that of any other ape. A prolongation is developed from each ventricle of the larynx, and these processes in the adult become enormous, uniting together in front over the windpipe, and forming one great sac which extends down between the muscles to the axilla. There are, however, no cheek pouches. The canine teeth, especially of the adult males, are very large.

The chimpanzee and gorilla together form the genus *Troglodytes*. Both of these species agree with the orang in being destitute of any rudiment of a tail, in having no cheek pouches, and no naked spaces at the hinder part of the trunk, as also in possessing tusk-like canines, and in the habit of resting on the knuckles of the hand in walking

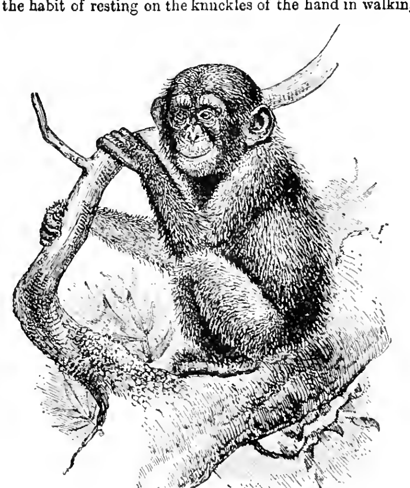


FIG. 2.—The Chimpanzee (*Troglodytes niger*). From Mr Wolf's *Sketches*, vol. i. pl. i.

on the ground and of mainly dwelling in trees. The chimpanzee (*T. niger*) is found in Western Africa, from the Gambia to the Benguela, and extending inland to 28° E.

long. It is the most man-like of the latisternal apes in the proportions of its arms, as these only reach a little below the knees when the body is placed upright. It is of moderate stature, never appearing to exceed 5 feet in height. In disposition it is lively and intelligent, and its playfulness in captivity contrasts greatly with the lethargy

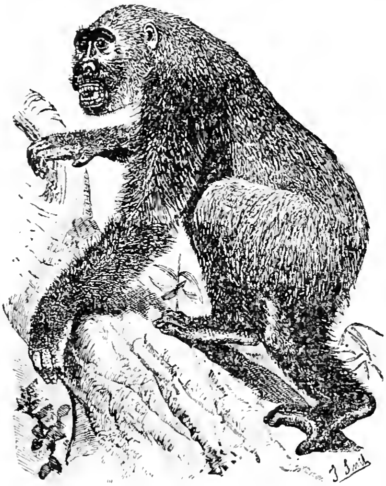

FIG. 3.—The Gorilla (*Troglodytes gorilla*). From *Trans. Zool. Society* vol. iv. pl. 43

of the orang. The forehead is not rounded, but a bony, supra-orbital ridge extends transversely above the eyes. Its ears are very large, and it has distinct eyebrows, eyelashes, and whiskers. The pollex reaches nearly or quite to the base of the first phalanx of the index of the hand, and the hallux to the proximal end of the second phalanx of the index of the foot. There is no *os intermedium* in the carpus. The laryngeal sacculus may, as in the orang, extend downwards to the axilla. There are thirteen pairs of ribs.

The gorilla (*T. gorilla*) is also West African, but has a less extended range than the chimpanzee, namely, between the Cameroon and Congo rivers only. It is the largest ape known, attaining a bulk of body considerably exceeding that of man, though, on account of the shortness of its legs, it never seems to exceed the height of 5 feet 6 inches. It was first made known to moderns by Dr Thomas Savage, but it appears to have been seen by Hanno of Carthage,[1] in his voyage south of the pillars of Hercules. The gorilla has not such dark hair as has the chimpanzee, being blackish-dun in colour, and becoming grey when old. Its skin, however, is black. Its arms are longer than those of its congener, reaching half-way down the shin. Its pollex reaches but very little beyond the proximal end of the first phalanx of the index of the hand (slightly further than in the chimpanzee), and its hallux to about the distal end of the proximal phalanx of the index of its foot. The fingers and toes, however, are curiously syndactyle, being bound together by the integument to the ends of the proximal phalanges. The forehead is not rounded, the supra-orbital crest being more prominent than even in the chimpanzee; the ears too are smaller relatively. The larynx is provided with enormous air-sacs, communicating with the ventricles and meeting over the trachea, and extending to the axilla with age. There is no os intermedium in the carpus, and there are thirteen pairs of ribs.

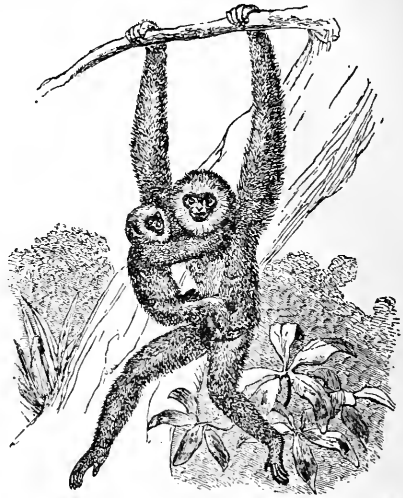

FIG. 4.—The Entellos-like Gibbon (*Hylobates entelloides*). From *Archives du Muséum*, vol. ii. pl. 29.

The gibbons, or long-armed apes, form the genus *Hylobates*, confined in the present day to the south-eastern continent of Asia and the Indian Archipelago. There are several species, but individual variation and sexual difference in colour are so great that their limits are not yet well defined. One well-marked species, the largest of the genus, is the siamang (*H. syndactylus*) of Sumatra, which is remarkable as being the ape with the best developed chin and widest breast-bone. It has also the second and third toes united by skin down to the last joint of each. Another well-marked form is the hoolock of Assam (*H. hoolock*). In the gibbons we first find that part upon which the body rests in sitting provided with naked callous spaces, termed (from that part of the haunch bone to which they are applied, the *ischium*) "ischial callosities;" they are, however, still small. Though vegetable feeders, the gibbons are probably less exclusively so than are the yet higher apes before noticed. In captivity their manners are gentle, although their activity is surprising; especially remarkable are the enormous distances they can swing themselves by their long arms. In spite of this length of arm, which seems to render their bodily proportions so unlike those of man, the length of leg, when compared with the length of the trunk of the body, is more human than in either of the two preceding genera. Another point in which they approach nearest to man, is the quality of voice which at least some of the species (*e.g. H. hoolock*) possess.

None of the gibbons have any rudiment of a tail, and they have no cheek pouches, but the canines are elongated and tusk-like. When the body is erect, the arms are so long that they reach the ground. The hallux is well developed, reaching to the middle or end of the proximal phalanx of the index of the foot, while the pollex only attains to, or reaches a little beyond, the proximal end of the

[1] See Pliny, *Nat. Hist.*, ii. 169, v. 8, vi. 200, ed. Sillig.

proximal phalanx of the index of the hand. There is an os intermedium in the carpus. The laryngeal sacs are no longer prolongations of the laryngeal ventricles, but open into the larynx above the false vocal chords. The number of species is, as has been said, doubtful, but the following kinds are often reckoned as distinct,—*Syndactylus, Lar, Leuciscus, Agilis, Mulleri, Rafflesii, Hoolock, Entelloides, Pileatus,* and *Funereus.*

On leaving the gibbons, which close the series of Anthropoid apes, we come at once upon animals of very different aspect, and from creatures devoid of any vestige of a tail, we pass at once to monkeys, which have that organ at its maximum of development. These are the two genera *Semnopithecus* and *Colobus*, which so closely resemble each other as to be hardly separable, but for their different geographical distributions. Together they form the sub-family *Semnopithecinæ*, and agree in having, as well as the long tail, arms shorter than the legs, and a slender body. They have small ischiatic callosities, but no cheek pouches. Their nails are compressed and pointed. Their stomach is very elongated and exceedingly sacculated, and their hindermost lower grinding tooth has five tubercles. The laryngeal sac opens medianly into the front of the larynx, and is an extension of the thyro-hyoid membrane. The thumb is small or absent.

The genus *Semnopithecus*, in which there is a small thumb, is confined to South-Eastern Asia from the Himalaya southwards, the Indian Archipelago being its head-quarters. One species, *S. entellus* (the hounaman), is an object of religious veneration to the Hindoos. Another very remarkable kind is found in Borneo. It is *S. asalis* (the kahau, or proboscis monkey), and, as its name im-

FIG. 5.—The Proboscis Monkey of Thibet (*Semnopithecus roxellanæ*). From Milne-Edwards's *Recherches des Mammifères*, pl. 36.

plies, it has an exceedingly long nose. In the young state, the nose is much smaller relatively, and is bent upwards. No similar structure was known to exist in any other ape whatever till quite recently. Now, however, the Rev. Father David (a Lazarist missionary, who has made many other important discoveries in zoology), has found high up in the cold forests at Moupin in Thibet, a large well-clothed species, with a small but distinct nose excessively turned up, on which account the name *S. roxellanæ* has been bestowed upon it. It is remarkable that a form, reminding us of the young condition of *S. nasalis*, should have been discovered in a region so remote from the island of Borneo as is Thibet. It is also very remarkable that a monkey of a genus the home of which is the warm Archipelago of India, should be found in forests where frost and snow last several months in the year, when their only food is tree buds, and tender shoots and twigs. The species of the genus to be mentioned, besides *Entellus, Nasalis,* and *Roxellanæ*, are,—*Nemœus, Leucoprymnus, Latibarbatus, Obscurus, Nestor, Cucullatus, Johnii, Priamus, Cristatus, Maurus, Femoralis, Auratus, Frontatus, Siamensis, Mitratus, Flavimanus, Rubicundus, Albipes, Nigripes,* and *Schistaceus.*

The genus *Colobus* is exclusively African, but the species composing it only differ from the *Semnopitheci*, in that the thumb is generally absent or reduced to a small tubercle, which may or may not support a nail. The species are —*Guereza, Verus, Temminckii, Vellerosus, Fuliginosus, Satanas, Angolensis, Ursinus, Ferrugineus, Kirkii,* and *Palliatus.*

We now come to the concluding genera of the apes of the Old World, together forming the third sub-family *Cynopithecinæ*. This is a very natural group, but one exceedingly difficult to subdivide in a satisfactory manner, because the different characters gradually alter as we pass from round-headed, long-tailed, and comparatively slender monkeys to dog-faced, short-tailed, and massive baboons. All the *Cynopithecinæ* agree in having pretty well-developed thumbs and a single stomach, as also in having the sides of the face distensible, serving as pockets wherein food may be temporarily stored, and technically called "cheek pouches." The hair is often annulated. The ischiatic callosities are larger than in the forms hitherto noticed, and in some kinds these parts become greatly swollen at the period of sexual excitement, the enlargement extending sometimes (as in *Macacus cyclopis*) even to the tail. The male external generative organs tend to assume a bright and varied coloration, which is often accompanied with vivid hues on and about the face. By common consent, the *Cynopithecinæ* are divided into at least three genera, and by some naturalists (*e.g.* M. Isidore Geoffroy St Hilaire) they have been divided into as many as seven.

The first genus, *Cercopithecus*, includes those species of the sub-family, which by their length of tail and comparative slenderness, most nearly approach the members of the preceding sub-family. Many of the species (*e.g.* the Diana and white-nosed monkeys) are very attractive animals. Commonly the *Cercopitheci* have four tubercles to the last lower molar. The talapoin monkey (*C. talapoin*) has been made the type of a separate genus (*Miopithecus*), because it has but three such tubercles, while the mangabeys and white-eyelid monkeys (*C. æthiops, collaris,* and *fuliginosus*) have been separated off into a genus *Cercocebus*, because in them the last lower molar has five tubercles. All the *Cercopitheci* (including *Miopithecus* and *Cercocebus*) are African forms. Besides those already mentioned, the following species have been described by authors :—*Nictitans, Petaurista, Cephus, Mona, Monoides, Diana, Labiatus, Leucampyx, Pygerythrus, Lalandii, Sabæus, Cynosurus, Ruber, Pyrrhonotus, Callitrichus, Rufoviridis, Albigena, Erythrogaster, Werneri, Melanogenys, Ludio, Erythrarchus, Ochraceus, Flavidus, Lunulatus,* and *Erxlebenii.*

The next genus, *Macacus*, is Asiatic, with the exception of the Barbary ape, or magot (*M. inuus*), which is found in Northern Africa and on the Rock of Gibraltar. Already, in some of the *Cercopitheci*, notably in the mangabeys, the muzzle has acquired a greater prolongation. This becomes still more marked in the *Macaci*. It is this greater production of muzzle, the greater size in the ischiatic callosities, the frequent shortness of the tail, and the different geographical distribution, which can alone be given as differentiating these animals from the *Cercopitheci*. In some kinds the tail is long. Occasionally (as in the wanderoo, *M. silenus*) it is tufted at the end and short. Sometimes, as in *M. nemestrinus*, it is very short, and occasionally, as in *M. inuus*, it is absent. On account of this absence of tail, this species has sometimes been made the type of a distinct genus, *Inuus*.

Another species, *M. niger* (from Celebes and Batchian), has, on account of the much greater production of its muzzle, been made the type of another genus, termed *Cynopithecus*.

The *Macaci* present us with the most northern forms of apes, namely, that of Gibraltar, and *M. speciosus* of Japan. Father David has lately brought from Moupin, in Thibet, a new species (*M. thibetanus*) which inhabits snowy mountains, and is clothed suitably for such a habitat, in thick and dense fur. In addition to the *Macaci* already mentioned, we may name the species *Sinicus*, *Pileatus*, *Aureus*, *Cynomolgus*, *Silenus*, *Rhesus*, *Nemestrinus*, *Thibetanus*, *Ochreatus*, *Palpebrosus*, *Brunneus*, *Rufescens*, *Rheso-similis*, *Erythræus*, *Cristatus*, *Tcheliensis*, *Cyclopis*, *Inornatus*, *Sancti-johannis*, *Lasiotus*, *Assamensis*, *Maurus*, *Philippinensis*, and *Nigrescens*.

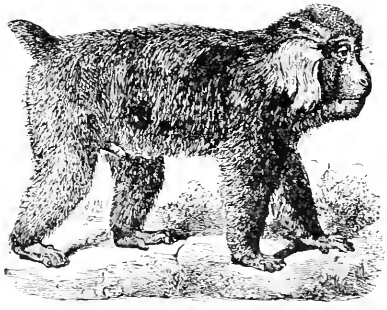

FIG. 6.—The Thibet Macaque (*Macacus thibetanus*). From Milne-Edwards's *Recherches des Mammifères*, pl. 34.

The remaining apes of the Old World are the baboons, which are entirely confined to Africa, and to that part of Asia which is zoologically African, namely, Arabia. These animals, which constitute the genus *Cynocephalus*, have the characters of the *Macaci* still further developed in having still larger callosities, and a muzzle so extremely produced as to give the head the appearance of that of a dog, whence their generic name. The general form has also here become very massive, and the limbs being sub-equal in length, the appearance, like the locomotion, is quadrupedal. But the baboons have not only the muzzle so greatly produced, they have also the nostrils terminal in position like those of a hound and unlike what we have yet met with. The species *C. gelada* of Abyssinia and *C. obscurus* form exceptions to this condition, as they have the nostrils placed as in the *Macaci*, on which account they have been made the type of a distinct genus, *Theropithecus*.

In the other *Cynocephali*, the tail may be moderately long, as in *C. hamadryas*, or very short, as in the mandrill, *C. mormon*. In the last-named species we again meet with much bulk of body, as it exceeds the chimpanzee in this respect. It is also remarkable for its bright coloration, the cheeks being brilliant blue, the

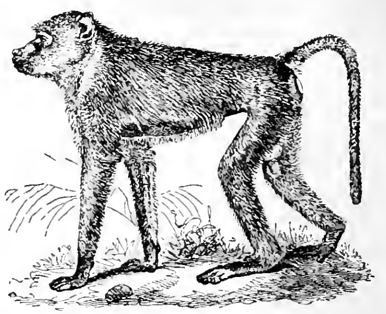

FIG. 7.—The Babuin Baboon (*Cynocephalus babuin*). From *Archives du Museum*, vol. ii. pl. 34.

nose vermilion, and the beard golden-yellow. Other species described are *Sphinx*, *Olivaceus*, *Babuin*, *Anubis*, *Obscurus*, *Doguera*, *Porcarius*, and *Leucophæus*.

The baboons are the least arboreal and the least frugivorous of the Old World apes, some species, *e.g.*, the chacma of Southern Africa (*C. porcarius*), living habitually amidst rocks, and feeding on eggs, large insects, and scorpions, as well as on vegetable food.

In the whole series of Old World apes we find the same number of different kinds of teeth as in man, the dental formula being—

$$\text{I. } \frac{2-2}{2-2} \text{ C. } \frac{1-1}{1-1} \text{ P.M. } \frac{2-2}{2-2} \text{ M. } \frac{3-3}{3-3} = \frac{16}{16};$$

or thirty-two teeth in all. Again, in the whole series the two nostrils are divided the one from the other by a narrow septum; and if the skull be examined, a long bony tube (the *meatus auditorius externus*) is seen to lead inwards on each side to the internal ear. Moreover, the thumbs, when present, are always more or less opposable to the other fingers.

In passing to the second family of apes—the *Cebidæ*, or apes of the New World—we find them to form a very distinct and easily-defined group, and a little experience readily enables an observer to pronounce at a glance that a given ape belongs either to the Old or the New World, as the case may be.

The *Cebidæ* are more thoroughly arboreal in their habits than are the *Simiadæ*. Ranging over tropical America, they have their headquarters in the forests of Brazil, a region where most animal forms put on a more decidedly arboreal character. Accordingly, it is amongst the *Cebidæ* that we meet with, for the first time, a special arboreal organ—namely, a prehensile tail. Such a tail has its free end curled, and capable of grasping with greater or less tenacity the objects about which it coils. Again, in the *Cebidæ*, the septum between the nostrils is broad, instead of narrow, imparting to the physiognomy a markedly different character. In passing to these American apes we entirely lose cheek pouches and ischial callosities; while the thumb, even where best developed, is capable of but a very partial opposition to the other fingers, bending almost in the same plane with the latter, so as to be more like a fifth finger than a thumb. We also constantly find an additional premolar tooth on each side of each jaw, and that bony tube, the *meatus auditorius externus*, is wanting

None of the *Cebidæ* attain the bulk of the larger baboons, nor have any such prominent muzzles as have the latter.

The *Cebidæ* are subdivisible into five sub-families: *Cebinæ*; 2. *Mycetinæ*; 3. *Pitheciinæ*; 4. *Nyctipithec* and, 5. *Hapalinæ*.

The first sub-family consists of the four genera, *Ateles*, *Eriodes*, *Lagothrix*, and *Cebus*.

The genus *Ateles* is composed of the spider monkeys, which, as their name implies, have long and slender limbs. They have also a very long tail, which is in the highest degree prehensile, being naked beneath towards the tip, for more secure prehension. So powerful is the grasp of this organ that the whole body can be sustained by it alone. It even serves as a fifth hand, as detached objects, otherwise out of reach, can be grasped by it, and brought towards the hand or mouth. Their prehension is in other respects exceptionally defective, as the spider monkeys alone amongst the *Cebidæ* (like the *Colobi* amongst the *Simiadæ*) have the thumb reduced to a mere tubercle. Their laryngeal sac opens medianly, but from the back part of the trachea, just below the cricoid cartilage.

The spider monkeys are very gentle in disposition, and, by this and by their long limbs and special fitness for tree-life, seem to represent in an analogous manner in the New World the gibbons of the Old. Nevertheless, in spite of their admirable adaptation for arboreal life, their comparatively slow progression offers a marked contrast to the vigorous agility of the gibbons. Their hair is long, but not woolly. Species described are—*Ater*, *Pentadactylus*, *Paniscus*, *Marginatus*, *Belzebuth*, *Melanochir*, *Hybridus*, *Vellerosus*, *Albifrons*, *Rufiventris*, *Variegatus*, *Griescens*, *Cucullatus*, and *Fuscipes*.

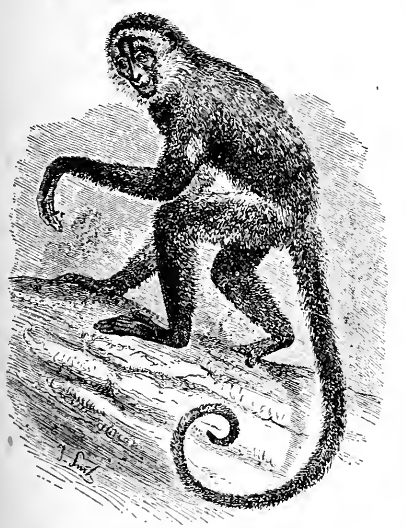

FIG. 8.—The Black-handed Spider Monkey (*Ateles melanochir*). From *Pro. Zool. Soc.* 1871, pl. 15

Three species of ape having much general resemblance to spider monkeys have been erected into the genus *Eriodes* (*E. arachnoides*, *hemidactylus*, and *hypoxanthus*). These animals, which are from South-Eastern Brazil, have the fur woolly, the thumb more or less rudimentary, the nails very laterally compressed, and the nostrils more approximated than in the other *Cebidæ*.

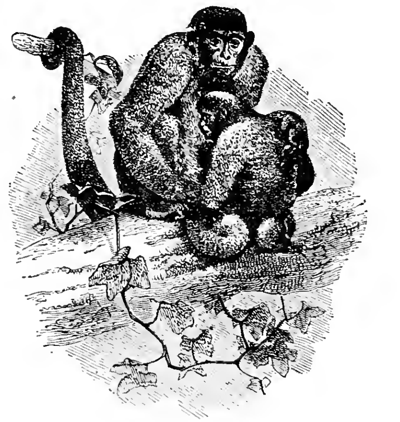

FIG. 9.—Humboldt's Lagothrix (*Lagothrix Humboldtii*). From *Pro. Zool. Soc.* 1863, pl. 31.

The woolly monkeys, *Lagothrix*, differ from the two preceding genera in having the thumbs well developed. Their nails are compressed laterally, as in *Eriodes*, but their nostrils are not approximated. As their name implies, their fur is woolly. Like *Eriodes* and *Ateles*, they have the tail strongly prehensile, and naked beneath towards the tip. The species which have been described as distinct are—*Canus*, *Humboldtii*, *Castelnaui*, *Tschudi*, and *Geoffroyi*.

The genus *Cebus*, the typical genus of American apes, is composed of the sapajous, so commonly seen in captivity, and so much used for the exhibition of tricks of various kinds. Smaller in size, they are more robust in form than are the spider monkeys. They have well-developed thumbs, and their tail is curled at the end, but, not being naked beneath, is less strongly prehensile than in the three preceding genera. The sapajous have a pleasing voice, a flute-like whistling tone. The different species are very ill-defined, the individual differences being so numerous and so considerable. The species described are the following:—*Capucinus*, *Hypoleucus*, *Elegans*, *Robustus*, *Apella*, *Cirrifer*, *Flavus*, *Castaneus*, *Barbatus*, *Frontatus*, *Chrysopus*, *Variegatus*, *Versicolor*, *Leucocephalus*, *Flavescens*, *Annellatus*, *Subcristatus*, *Capillatus*, *Fatuellus*, and *Vellerosus*.

The next sub-family of American apes is very distinct, consisting, as it does, of a single genus, *Mycetes*, composed of the howling monkeys. These creatures are the most bulky of the American apes, and are those the muzzles of which are the most projecting. If the spider monkeys may be considered the analogical representatives of the gibbons, the howlers may similarly be esteemed those of the baboons. They are sluggish, and apparently stupid animals, but have a wonderful power of voice, facilitated by an enormous distension of the body of the hyoid bone into a large, deep, bony cup, sheltered between the jaws, which are specially deep for that purpose. Into this cup is received one of the three or five sacs with which the larynx is provided. The thyroid cartilage is very large. The howlers have long, very prehensile tails, naked beneath towards the tips. Their thumbs are well developed. Some of the species show much brilliance of colour, with bright red or golden hair on the flanks. There is, however, so much individual variation, or so many local varieties, that the species are as yet very little determined. The sexual difference in colour is great in one species—the male being deep black, and the female pale straw colour. Amongst the species described may be named—*Seniculus*, *Ursinus*, *Caraya*, *Rufimanus*, *Niger*, *Villosus*, and *Palliatus*.

The third sub-family of American apes is composed of very peculiar forms, termed Sakis, which are subdivided into two genera, *Pithecia* and *Brachyurus*, according as the tail is long or short. They are together distinguished from all the *Cebidæ* yet noticed, by not having the tail prehensile, even when long; also by having the lower incisor teeth inclined forwards, instead of standing up vertically. Great differences as to the hair exist in this group, some having long hair over the whole body, others on the head, and others on the chin and cheeks, while a species of Brachyurus (*B. calvus*) has the head naturally bald. Of the genus *Pithecia*, the following species have been described:—*Leucocephala*, *Rufiventer*, *Monachus*, *Satanas*, *Chiropotes*, *Albinasa*, and *Chrysocephala*. Of *Brachyurus*, besides *Calvus*, only *Rubicundus* has as yet been described.

The *Brachyuri* are the only American apes with short tails, and they are the least arboreal, frequenting bushes rather than trees. They are very timid creatures, and gentle, and rather slow in their movements. It is but very rarely that any of the *Pitheciinæ* have been brought to Europe alive.

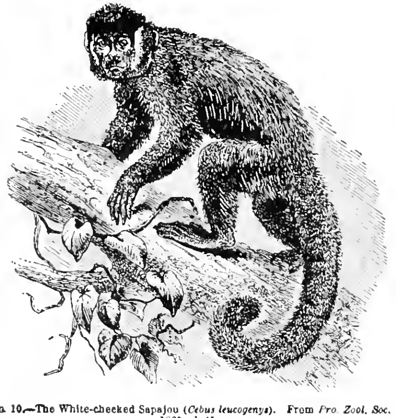

FIG. 10.—The White-cheeked Sapajou (*Cebus leucogenys*). From *Pro. Zool. Soc.* 1865, pl. 45

The next sub-family, *Nyctipithecinæ*, contains three genera, which have a long but not prehensile tail, fairly-developed thumbs, and vertical lower incisor teeth. These animals are, in part at least, insectivorous.

The typical genus, *Nyctipithecus*, contains only the night-apes, or douroucoulis (*N. felinus*, *lemurinus*, *oseryi*, *rufipes*, and *Spixii*), which have, in harmony with their noctural habits, enormous eyes. The orbits, though closely approximated, are nevertheless separated by a complete bony system. The head is rounded, but greatly drawn out posteriorly. The nostrils are rather approximated.

The beautiful little squirrel monkey, or Saimiri, and three allied species (*Ch. ustus*, *entomophagus*, and *Œrstedii*), form the genus *Chrysothrix*. They are distinguished from all other apes by the great backward prolongation of the bony cranium, the orbits of which, though smaller than those of *Nyctipithecus*, are, nevertheless, separated, but by an imperfect bony septum.

A few other kinds of American apes, together forming the genus *Callithrix*, somewhat resemble the night apes, but

FIG. 11.—The Lemurine Night Ape (*Nyctipithecus lemurinus*). From *Archives du Museum*, vol. iv. pl. 2.

that the eyes are much smaller, and the nostrils wider apart. They differ from *Chrysothrix* in having small canine teeth, and the tail furnished with long hairs. The species of this genus are—*Moloch*, *Personatus*, *Amictus*, *Gigo*, *Melanochir*, *Discolor*, *Donacophilus*, *Ornatus*, and *Castaneoventris*.

There remains now to notice but one more group of apes, those which have been classed as the last sub-family—the *Hapalinæ*, marmosets, or oustitis. These animals are so different from all that have gone before that there is probably almost as much to be said for ranking them as a family by themselves as for considering them, as is here done, but a sub-family. Much, however, as they differ from all the other apes, they manifest their affinity to the rest of the *Cebidæ* by the absence of the *meatus auditorius externus*, and by the presence of the extra premolar tooth on each side of each jaw. They have, however, the same total number of teeth as have man and the *Simiadæ*. This is occasioned by their not possessing any third true molar, either above or below; so that their dentition thus differs from that of the Old World apes in two points, instead of only one. In all the apes we have yet noticed, except the orang, the hallux is well developed, while in the marmosets it is exceedingly small. The hand, however, is yet more exceptional, as the thumb is not at all opposable, while, in common with all the other fingers, it is furnished with a long, curved, and pointed claw. The tail is not prehensile, but long, and furnished with more or less elongated hairs. In several, and especially the more commonly seen species, a tuft of long hairs projects outwards and backwards on each side of the head. These animals are very small, the largest being about the size of squirrels. They are, like squirrels, active in their motions, and arboreal in their habits, living in small troops, and eating insects as well as fruit. They are very difficult to keep in captivity in northern climates; but, nevertheless, they have occasionally bred in England, bringing forth as many as three at a birth, while all the other apes habitually bring forth but one. There are many different species of marmosets, and they have been divided into two genera, according as the lower canine (eye) teeth are or are not

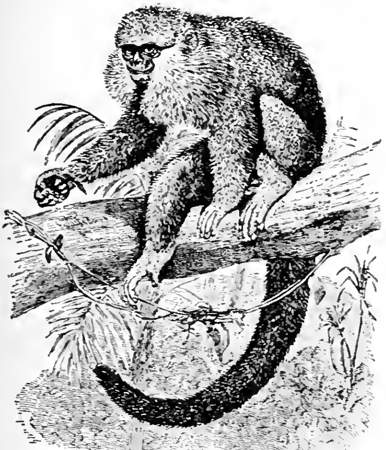

FIG. 12.—The Moloch Callithrix (*Callithrix moloch*). From *Archives du Muséum*, vol. iv. pl. 3.

decidedly larger than the incisors (cutting-teeth) between them; those kinds in which the inferior and incisor canines are almost of equal length being retained in the genus *Hapale*, while those in which the lower incisors are much shorter

FIG. 13.—The Golden Marmoset (*Midas chrysoleucus*). From *Pro. Zool. Soc.* 1868, pl. 24.

than the adjacent canines are taken to form the genus *Midas*. It seems doubtful, however, whether this generic distinction can ultimately be maintained, an intermediate condition existing in some forms. The species of the genus *Hapale* are—*Jacchus*, *Albicollis*, *Aurita*, *Humeralifer*, *Penicillata*, *Leucocephala*, *Melanura*, and *Pygmæa*.

The species of the genus *Midas* are—*Rosalia*, *Chrysomelas*, *Œdipus*, *Geoffroyi*, *Bicolor*, *Ursulus*, *Rufimanus*, *Labiatus*, *Mystax*, *Rufoniger*, *Devilli*, *Nigrifrons*, *Flavifrons*, *Illigeri*, *Weddellii*, *Leucogenys*, *Melanurus*, *Argentatus*, *Chrysoleucus*, *Lagonotus*, *Graellsi*, *Pileatus*, *Elegantulus*, and *Rufiventer*.

The characters of the subdivisions of the ape group may be synoptically expressed as follows:—

Family I. SIMIADÆ.

P.M. $\frac{2}{2}$ M. $\frac{3}{3}$; a bony *meatus auditorius externus;* pollex opposable, if present; tail never prehensile; internasal septum narrow; often cheek pouches; often callosities; pectoral limbs sometimes greatly exceeding the pelvic limbs in length; pelvic limbs never much longer than the pectoral limbs; Old World habitat.

Sub-Family I. *Simiinæ.*

Pectoral limbs much longer than pelvic limbs; no tail; no cheek pouches; cæcum with a vermiform appendix; sternum broad; sometimes no os intermedium in the carpus; stomach simple.

1. *Simia.*—Head vertically produced; arms reaching to ankle; ribs, twelve pairs; an os intermedium; hallux very small; no ischiatic callosities; hair red; habitat Asiatic.

2. *Troglodytes.*—Head not vertically produced; arms not reaching more than half down the shin; ribs, thirteen pairs; no os intermedium; hallux well developed; no ischiatic callosities; hair black, dun, or grey; habitat African.

3. *Hylobates.*—Head not vertically produced; arms reaching to the ground; an os intermedium; hallux well developed; small ischiatic callosities; habitat Asiatic.

Sub-Family II. *Semnopithecinæ.*

Pelvic limbs longer than pectoral limbs; tail very long; no cheek pouches; no vermiform appendix; sternum narrow; an os intermedium; ischiatic callosities; stomach complicated by sacculations; third lower molar always with five tubercles.

4. *Semnopithecus.*—Thumb small; habitat Asiatic.

5. *Colobus.*—Thumb generally absent; habitat African.

Sub-Family III. *Cynopithecinæ.*

Pelvic and pectoral limbs sub-equal in length; tail long, or short, or absent; cheek pouches; no vermiform appendix; sternum narrow; an os intermedium; ischiatic callosities present, often very large; stomach simple; third lower molar sometimes with four tubercles.

6. *Cercopithecus.*—Muzzle more or less short; callosities moderate; last lower molar generally with four tubercles; tail long; habitat African.

7. *Macacus.*—Muzzle more or less elongated; callosities rather large; last lower molar with five tubercles; tail long, short, or absent; nostrils not terminal; habitat Asiatic, North African, or European.

8. *Cynocephalus.*—Muzzle very long; callosities very large; last lower molar with five tubercles; tail more or less short; muzzle swollen by enlargement of maxillary bone; nostrils almost always terminal; habitat African.

Family II. CEBIDÆ.

P.M. $\frac{3}{3}$; no bony *meatus auditorius externus;* pollex never opposable; tail often prehensile; internasal septum broad; no cheek pouches; no ischiatic callosities; no vermiform appendix; always an os intermedium; pectoral limbs never more than slightly exceeding[1] in length the pelvic limbs; pelvic limbs sometimes much longer than the pectoral limbs; New World habitat.

Sub-Family I. *Cebinæ.*

M. $\frac{3}{3}$; incisors vertical; tail long and prehensile; hyoid bone moderate; thumb present or absent.

9. *Ateles.*—Form slender; limbs very long; fur not woolly; internasal septum as broad as usual in Cebidæ; thumb absent; tail distally naked beneath; nails not much laterally compressed and pointed.

10. *Eriodes.*—Form slender; limbs very long; fur woolly; internasal septum narrower than usual in Cebidæ; thumb rudimentary; tail distally naked beneath; nails exceedingly compressed laterally, and pointed.

[1] Only at all so in *Ateles*.

11. *Lagothrix.*—Form rather robust; limbs moderate; fur woolly; internasal septum as broad as usual; thumb well developed; tail distally naked beneath.

12. *Cebus.*—Form rather robust; limbs moderate; fur not woolly; internasal septum as broad as usual; thumb well developed; tail not naked beneath distally.

Sub-Family II. *Mycetinæ.*

M. $\frac{3}{3}$; incisors vertical; tail long and prehensile, naked beneath distally; hyoid bone enormous; form of body massive; thumb well developed; internasal septum as broad as usual.

13. *Mycetes.*

Sub-Family III. *Pitheciinæ.*

M. $\frac{3}{3}$; incisors inclined outwards distally; tail long or short, never prehensile; hyoid bone moderate; thumb well developed; internasal septum as broad as usual.

14. *Pithecia.*—Tail long.

15. *Brachyurus.*—Tail short.

Sub-Family IV. *Nyctipithecinæ.*

M. $\frac{3}{3}$; incisors vertical; tail long, not prehensile; hyoid bone moderate; thumb well developed.

16. *Nyctipithecus.*—Head rounded; eyes enormous; nostrils rather approximated.

17. *Chrysothrix.*—Head exceedingly elongated; eyes large, closely approximated; canines well developed; hair of tail rather short.

18. *Callithrix.* — Head small, depressed, and not elongated; nostrils widely separate; canines small; hair of tail elongated.

Sub-Family V. *Hapalinæ.*

M. $\frac{2}{2}$; incisors vertical; tail long, not prehensile; hyoid bone moderate; thumb elongated, not at all opposable; hallux very small; a long curved and pointed claw to all the digits, except the hallux.

19. *Hapale.*—Lower incisors and canines of equal length.

20. *Midas.*—Lower canines much longer than the lower incisors.

THE ANATOMY OF APES.

To describe generally the anatomy of apes would be, in fact, to describe in an elementary manner the general anatomy of man. It is necessary, therefore, here to assume that the reader has already an elementary knowledge of human anatomy, and to refer such readers as have not such knowledge to the article ANATOMY.

THE EXTERNAL FORM AND CLOTHING.

The difference in bulk between the different members of the group (*e.g. Troglodytes* and *Hapale*) is extreme, being greater than that between a man and a common squirrel.

The proportions of the body as regards the relative lengths of the two pairs of limbs one with the other, and both with that of the trunk, vary considerably. Both pairs may be much elongated, as in *Ateles* and *Hylobates*, and either sub-equally, as in the first of these genera, or with the arms very greatly in excess, as in the second. The legs may be excessively short, and the arms, at the same time, excessively long, as in the orang. Both pairs may be short and sub-equal, as often in the *Cynopithecinæ*. Only in the *Nyctipithecinæ* and *Hapalinæ* does the excess in length of the lower limbs over the upper exceed or equal that which is found in man. The length of the tail presents some noteworthy points. At its first appearance it is found at once at its greatest absolute length, and also greatly developed relatively, being about twice the length of the trunk. Its greatest relative length is, however, attained in *Ateles*, where it reaches three times the length of the trunk. The constancy of the degree of its development varies much in different groups. In the greater number of genera it is long in all the species, and in some (*Simia*, *Troglodytes*, and *Hylobates*) it is absent in all. In others it may be long or short, or completely absent, *e.g.*, in *Macacus*. The form of the head presents great differences—it may be rounded, as, *e.g.*, in *Ateles;* produced vertically, as in *Simia;* drawn out posteriorly to an extreme degree, as in *Chrysothrix;* or anteriorly, as in *Cynocephalus*. A production of the muzzle, necessitated by the presence of large teeth, exists already in *Troglodytes;* but in the baboons, not only is this prolongation carried much further, but the terminal position of the nostrils gives an emphatically dog-like aspect to the face.

The eyes may be small compared with the size of the head, as in the baboons; they may, on the contrary, attain a relatively enormous size, as in *Nyctipithecus*. They are always forwardly directed, and never much more separated one from another than in man. They may, however, be much more closely approximated, as notably in *Chrysothrix*.

The external ears are always well developed, and have very generally their postero-superior angle pointed. They may be large and small in the same genus, as in *Troglodytes*. Only in the gorilla do we find present, even in a rudimentary condition, that soft depending portion of the human ear which is termed the "lobule."

The nose has scarcely ever more than a very slight prominence, and yet an enormous development is to be met with in *Semnopithecus nasalis;* while in *S. roxellanæ* we find a sharply prominent, though smaller and extremely upturned, nose. The hoolock gibbon also possesses a prominent but slightly aquiline nose. The terminal position of the nostrils in *Cynocephalus* has been just mentioned. These apertures may be closely approximated, as in all the *Simiadæ*, or they may be separated one from the other by a broad septum, as in the *Cebidæ*, its breadth, however, varying somewhat in different genera, as, *e.g.*, in *Ateles* and *Eriodes*, and in *Callithrix* and *Nyctipithecus*.

The lips are generally thin, but may be very extensive, as in *Simia*.

The hands are generally provided with thumbs, though these organs (as in *Colobus* and *Ateles*) may be represented only by small nailless tubercles. The thumb (*pollex*) is more human in its proportions in the chimpanzee than in any other of the highest apes. As compared with the length of the hand, it is most man-like in the lowest *Cebidæ*, *e.g.*, *Chrysothrix* and *Hapale*. In spite of greater relative length, however, it may but little merit the name of thumb, as it is but slightly opposable to the other digits in any of the *Cebidæ*, and is not at all so in the *Hapalinæ*.

The *hallux* (great toe) is never rudimentary like the pollex. It is never, as it often is in man, the longest digit of the foot, but is constantly the shortest one. As compared with the entire length of the foot, it is most human in the chimpanzee and some gibbons, and smallest of all in the orang, and next smallest in *Hapale*. More detailed proportions will be more appropriately given in speaking of the skeleton.

Every digit is provided with a nail, except the hallux of the orang and those rudimentary tubercles already spoken of as representing thumbs in *Ateles* and *Colobus*. The nail of the hallux is flat in every species, but the other nails are never so flat as are the nails of man. The lateral compression of the nails becomes more strongly marked in some *Cebidæ*, *e.g.*, in *Eriodes*, but attains its extreme in the *Hapalinæ*, where every nail, except that of the hallux, assumes the form of a long, curved, and sharply-pointed claw.

All the apes, without exception, differ from man in having the body almost entirely clothed with copious hair, and especially in never having the back naked. In the gibbons, the *Semnopithecinæ*, and the *Cynopithecinæ*, naked spaces (*ischiatic callosities*) are present on that part of the body which is the main support in the sitting posture. These naked spaces increase in size as we descend through the series of *Cynopithecinæ*, and are subject to a tumefaction (sometimes excessive and extending to parts adjacent) at the season of sexual excitement. Such naked spaces are never found in any of the *Cebidæ*. No ape has so exclusive and preponderating a development of hair on the head and face as exists in most men. As to the head, long hair is found thereon in *Hapale œdipus* and in some of the *Semnopitheci*, whilst certain of the *Macaci* (as, *e.g.*, the Chinese bonnet monkey, *M. sinicus*) have the hair of the head long, and radiating in all directions from a central point on the sinciput. A beard is developed in the male orang, and *Cercopithecus Diana* has long hair on the cheeks and chin. The wanderoo (*Macacus silenus*) has the face encircled by a kind of mane of very long hairs, and many of the marmosets have a long tuft of hairs on each side of the head. The American apes exhibit some extremes respecting hair development. Thus in some of the howlers (as in some of the *Colobi* of the Old World) the hair of the flanks is greatly elongated. Some also have an elongated beard, but the latter structure attains its maximum of development in the couxio (*Pithecia satanas*). Some of *Pitheciinæ* have the hair of the whole body and tail very long, others have the head of the female furnished with elongated hair, while another species (*Brachyurus calvus*) has the head bald. Long hair may be developed from the shoulders, as in *Cynocephalus hamadryas* and *Hapale humeralifer;* or may form a tuft at the end of the tail, as in *Macacus silenus*, *Cynocephalus hamadryas*, and *Cynocephalus gelada*.

The direction of the hair may sometimes vary in nearly allied forms. Thus the hairs on the arm and forearm respectively may be so directed that the apices converge towards the elbow. Such is the case in most of the latisternal apes, yet in *Hylobates agilis* all the hair of both these limb segments is directed towards the wrist.

The hair presents generally no remarkable character as to its structure. It may, however, assume a very silky nature, as in *Hapale rosalia*, or assume the character of wool, as in *Eriodes*, and as in that remarkable form recently discovered by Father David, *Macacus thibetanus*. The last named species inhabits the snowy ranges of the Thibet mountains, and is provided for this habitat by a modification in its hairy clothing similar to that which suited the extinct mammoth for the severity of its Siberian home. This fact as to *M. thibetanus* has an interesting bearing on fossil forms, which we shall have to consider later.

Great brilliance of colour is sometimes found in the naked parts of the body, particularly in the *Simiadæ*, and especially in the regions of the face and sexual organs. In some of *Cercopitheci* and *Cynocephali*, rose colour, turquoise blue, green, golden yellow, and vermilion appear, in various combinations, in one or other or both of these regions, and become especially brilliant at the epochs of sexual excitement.

The Skeleton.

The skeleton of apes generally, if we except the tail, consists of but few more bones than that of man. The proportions of its parts, except as regards the relative length of the limb bones, are also much as in man; nor are their shapes, except those of the jaws and haunch bones, greatly different. The same general resemblance may be predicated of their minute structure, though the osseous tissue is generally rather dense, and the medullary cavity in the long bones small.

The Axial Skeleton.—The Skull.

The axial skeleton consists of the skull and the vertebral column, and the general shape of its more anterior portion, the skull, has already been indicated when speaking of the head as part of the external form. It is scarcely ever so evenly balanced on the occipital condyles as in man.

The artificial division of the skull into a *cranial* and a *facial* portion may be here conveniently adopted from human anatomy. The proportion of the latter portion to the former varies greatly from age and sex, owing mainly to the differences produced through the development of large and powerful canine teeth in the adult males of most species. This proportion also varies in an irregular manner as we descend (through the series of apes) from those which are most like man. Thus the facial part is already very large in the orang and chimpanzee, much more so than in *Semnopithecus*, where most of the ape cranial characters are moderately developed, or even than in many *Cercopitheci;* but it attains its maximum of relative size in the *Cynocephali*, above all in *C. porcarius*. In the *Cebidæ* the facial part is relatively smaller than in the *Simiadæ*, with the exception of *Mycetes*, while in *Chrysothrix* the facial portion of the skull is relatively smaller than even in man himself. The relation of the face to the cranium (or brain case) is best shown by the craniofacial angle, which is estimated by means of two lines, one drawn parallel to the base of the skull (from the front margin of the occipital foramen to the anterior end of the cerebral surface of the presphenoid), the other drawn from the front end of that base to the middle of the lower margin of the upper jaw.

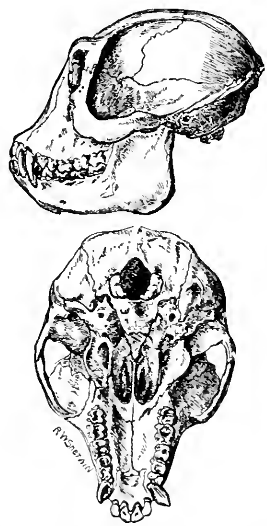

Fig. 14.—Side view and base of the skull of the Douc (*Semnopithecus nemæus*). From De Blainville.

No ape, especially no ape of the Old World, presents so elevated and rounded a contour in the frontal region as does man. It is in American forms, especially in the genus *Pithecia*, that we find the greatest resemblance to man in this respect: but the skull is lofty in the orang.

The convexity of the occiput is well marked in *Simia*, *Troglodytes niger*, and *Hylobates*, while in the inferior *Simiadæ* it is flat. Its maximum of production, however, is met with in the genus *Chrysothrix*.

Ridges for muscular attachment, or other bony prominences, more or less disguising the rotundity of the cranium, are very generally developed, except in the smallest species. Such ridges are met with at once at their very maximum of extent in *Troglodytes gorilla*. In that animal an

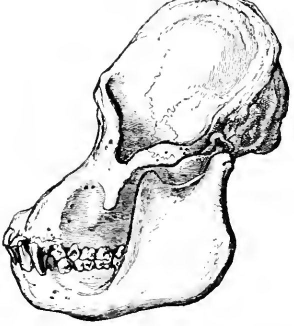

FIG. 15.—Side view of the skull of adult Orang (*Simia satyrus*). From *Trans. Zool. Soc.* vol. i. pl. 53.

enormous sagittal ridge traverses the middle of the sinciput antero-posteriorly, joining at its hinder end a prodigious lambdoidal crest for the insertion of the muscles of the neck. A very largely developed supra-orbital ridge runs transversely above the orbits, which it obliquely overhangs. The orang has no supra-orbital ridge, but in the other large *Simiadæ* all these ridges are more or less developed, and moderate sagittal and lambdoidal ridges are found in *Mycetes*, *Cebus*, *Pithecia*, and some other of the *Cebidæ*.

The mastoid process never attains in apes the large relative size it has in man; but it is prominent in the baboons and larger *Macaci*, as well as in *Troglodytes*, its development bearing relation to the size and weight of the head. As the mastoid diminishes we find that the under surface of the petrous bone assumes a swollen or "bullate" condition.

The orbits are in *T. gorilla* much as in man, but in the orang they are more rounded. They become very large in *Hylobates*, but attain an *enormous* size in *Nyctipithecus*. The extent to which each orbit opens into the adjacent temporal fossa, *i.e.*, the size and shape of the spheno-maxillary fissure, varies considerably. It is narrow and much elongated in the gorilla and in *Cynocephalus*; it is short in the *Semnopithecinæ* and in *Ateles*, but opens widely so as to expose the vidian foramen. It is most completely closed of all in *Mycetes*, where it sometimes all but disappears entirely. The olfactory chamber is narrow and deep in the lower *Simiadæ*. The cribriform plate of the ethmoid is generally separated from the presphenoid by the junction of the orbital plates of the frontal. Such, however, is not the case in the orang and chimpanzee, though it is so in the gorilla and in *Hylobates*.

The plane of the foramen magnum, as compared with the basi-cranial axis, varies with the projection of the occiput. It generally forms a less open angle with that axis than in man, but in *Chrysothrix* the angle is yet more open than in the human skull.

The zygomata are arched both outwards and upwards in the gorilla and some baboons, but decrease in relative as well as absolute size in the smaller forms,—notably in *Chrysothrix*. No long slender styloid process is normally attached to the skull, though such may be the case in *Cynocephalus*. The vaginal process never attains the size it does in man, though it is considerable in the gorilla, and sometimes noticeable in *Simia*. A bony *meatus auditorius externus* exists in all the *Simiadæ*, and is absent in the whole of the *Cebidæ*. In *Nyctipithecus* the ali-sphenoid is almost shut out from the parietal by the close approximation of the squamosal to the malar. In *Cebus* there is often a large malar foramen.

The premaxillary bones have throughout the apes a distinctness of development and a relative size not found in man, the sutures separating them from the maxillaries remaining visible, with the exception of the chimpanzee, after the adult dentition has been attained. The maxillaries themselves develop great swollen tuberosities in the *Cynocephali*, and a similar structure is developed even in *Macacus niger*.

The nasal bones are small, and generally flatter than in man. In the orang they are quite flat. They are convex in some of the *Semnopitheci* and in the *Cynocephali*, but the proboscis monkey has its nasal bones no more developed than have other species of its genus. The nasals seem to attain their maximum of relative size in *Mycetes*.

The lower jaw, or mandible, is always in one piece in adults. It is most man-like in the siamang, since we there alone find a slight chin. On the other hand, in *Hylobates* the angle is produced downwards and backwards, and we find the same in *Hapale*. Its maximum of relative size is attained in *Mycetes*, where the very broad ascending ramus serves to protect and shelter the enormously developed body of the hyoid.

Air cells may be developed, as in the gorilla, in the parts adjacent to the mastoid. Frontal sinuses are generally absent in the *Simiadæ*, being replaced by a coarse diploe. We find them, however, in the *Cebidæ*, and in *Cebus*

FIG. 16.—Side views of skull and hyoid bone of Howling Monkey (*Mycetes seniculus*). From De Blainville.

they are often larger than they are in man. The total length of the cerebral cavity is never so much as $2\frac{1}{4}$ times the length of the basi-cranial axis.

The sutures of the skull become entirely obliterated with age. In the gorilla the sutures assume a more dentated structure than is found in any other ape or in man. The internasal suture becomes early obliterated in most of the *Simiadæ*. The tentorium is sometimes ossified, as in the *Cebinæ* and *Mycetes*. From *Hylobates* downwards there is a small cerebellar fossa on the inner surface of the petrosal.

The Vertebral Column.

The vertebral or spinal column in all apes consists of the same regions as it does in man, and, with the exception of the coccygeal or caudal portion, these regions bear more or less the same proportions one to another as they do in him. That beautiful sigmoid curvature which exists in the human spine is not found in any ape; but the nearest approximation to it is found, not in the *Simiinæ*, but in the *Cynocephali*. In the latisternal apes the spinous processes are directed as in man, but in the rest their apices converge towards a single point in the back.

The *cervical region* is relatively more elongated than in man in *Hylobates*, *Cynocephalus*, and *Ateles*. The atlas is very man-like in *Troglodytes* and *Simia*, except that its transverse process is rather smaller and shorter relatively, and more curved dorsally. Except in *Ateles* and the *Simiinæ*, it is almost always perforated by the vertebral artery, instead of being merely grooved by it. In *Cynocephalus* the atlas is exceedingly massive, and may, by very rare exception, develop a spinous process. The spines of the cervical vertebræ do not bifurcate beyond the second, and generally the spine of the seventh vertebra is the longest, at least with the exception of that of the axis. In the gorilla and orang, however, the spines of the third, fourth, fifth, and sixth vertebræ are exceedingly elongated and longer than that of the seventh. The cervical neural laminæ are wider antero-posteriorly, the vertebral column being supposed horizontal, in *Hylobates* and *Ateles* than in other forms. Beneath the anterior articular process (prezygopophysis) a marked prominence—the metapophysis—may be developed, and is particularly conspicuous in *Ateles*. The costal plate of the sixth cervical is almost always larger than the homologous part in the other cervicals; but it predominates least in the chimpanzee and *Nyctipithecus*. The length of each centrum, compared with its breadth, is already greater in *Troglodytes* and *Simia* than in man. In others the dimensions are about equal, except that in *Cynocephalus*, *Ateles*, and *Mycetes* the length slightly exceeds the breadth.

The *dorsal vertebræ* vary in number from eleven, as sometimes in *Cercopithecus* and *Macacus*, to fourteen, as sometimes in *Hylobates*, or even to fifteen, as in *Nyctipithecus*. In the *Cebidæ*, above the *Hapalinæ*, the number rarely falls below thirteen In the orang the number is, as in man, twelve; in *Troglodytes* it is thirteen. The proportion of this region does not increase regularly with the number of its vertebræ. It attains its greatest relative length in *Ateles*, where it is over nine-twentieths of the total length of the spine without the tail; while in *Nyctipithecus* it is relatively shorter than in *Troglodytes* or *Simia*. The increase in transverse diameter of the bodies of the vertebræ, as we proceed from before backwards, is exceptionally great in *Hylobates* and *Cynocephalus* The *lumbar* region contains from four to seven vertebræ In the *Simiinæ* and *Cebinæ* there are four or five, though in *Cebus* the number is often six Its relative length is greatest in *Nyctipithecus*, *Chrysothrix*, the *Semnopithecinæ*, and *Cynocephalus*. It is least in the *Simiinæ* and *Ateles*. The number of dorsal and lumbar vertebræ, taken together, is seventeen in *Troglodytes* and *Simia*, eighteen (mostly) in *Ateles* and *Hylobates*, and nineteen in the rest. In most forms the dorsal and lumbar regions are about equal in length, but the lumbar region is the shorter in the *Simiinæ*, and less than half the length of the dorsal in the gorilla. The lumbar spinous processes are vertical, or project backwards in the *Simiinæ* and in *Ateles*; in the other forms they project strongly forwards, especially in the lower *Cebidæ*. The lumbar transverse processes always project outwards, more or less at right angles to the axis of the spine, or else forwards. In the *Simiinæ* and *Ateles* they are never inclined ventrally, but in some of the lower *Simiadæ* they begin to be so; in the lower *Cebidæ* they are so very decidedly. Only in *Troglodytes* and *Simia* are they inclined somewhat dorsally. In the last two genera the lumbar vertebræ are broader than their length; in most other forms length is in excess. The length of the individual lumbar vertebræ, compared with the dorsal (*e.g.*, the longest lumbar with the ninth dorsal), is greatest in the lower *Cebidæ*, rather less in the lower *Simiadæ*, and least in the *Simiinæ*.

The *sacrum* attains its greatest absolute length in the gorilla, but it is relatively longer than in man in all the *Simiinæ*. Of all the inferior apes, *Hylobates* has the relatively longest sacrum. The number of vertebræ in-included in the sacrum varies more or less with age. In the apes below the *Simiinæ* there are generally only two or three sacral vertebræ. In *Ateles*, *Hylobates*, and *Brachyurus*, there may be four; while in the *Simiinæ* there are always five, and sometimes six sacral vertebræ. In most apes the sacrum and lumbar vertebræ appear to lie in one slightly curved line. *Troglodytes* presents in this respect a great contrast to the human structure. In *Simia* the sacro-vertebral angle is rather more marked; but sometimes in *Cynocephalus* it is so much so as almost to rival that of man. The same may be said of the concavity of the anterior surface of the sacrum. It is most marked in the *Cynocephali*, and is more so in *Simia* than in *Troglodytes*. The sacrum gradually tapers posteriorly in *Troglodytes* and *Simia*, and more or less so in *Hylobates*. In the other *Simiadæ*, however, the sacrum is very wide at its anterior end, and it then very rapidly contracts backwards, so that the transverse diameter of the third sacral vertebra is very much narrower than that of the first. In the *Cebidæ* generally, and especially in *Ateles*, the contraction is not so marked.

The *caudal vertebræ* are always more than four in number, except in the *Simiinæ* and in *Macacus inuus*. In *Cynocephalus mormon* (the mandrill), however, there are some times only five vertebræ The short-tailed *Macaci* and *Brachyuri* have from about fifteen to seventeen caudal vertebræ, the shortness of the tail being occasioned rather by a diminution in the size of the component vertebræ than by a decrease in their number. In the other forms the number varies between twenty and thirty-three, the latter being the number attained in the genus *Ateles*. The

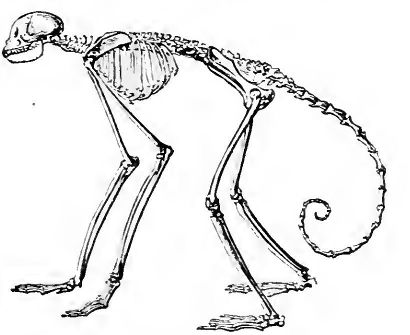

FIG. 17.—Skeleton of *Ateles Belzebuth*. From De Blainville

proportion borne by this region of the spine to all the more anterior parts is greatest in *Ateles*, almost three to one; in the other longest-tailed genera it is rarely so large as two to one. The absolute length of the tail is greatest in the *Semnopithecinæ*, where also the individual caudal vertebræ attain their greatest length, namely, two inches. The caudal vertebræ generally increase in length as we proceed backwards from the sacrum, till about the seventh, eighth, or ninth, which, with the tenth and eleventh, are the longest caudal vertebræ in most long-tailed forms. In *Ateles*, however, it is the eleventh, twelfth, thirteenth, and fourteenth vertebræ that are the longest. In the *Simiinæ* and in *Inuus* the caudal vertebræ decrease in length as we proceed backwards. Except in the forms just named, all the first four caudal vertebræ possess a complete neural arch, sometimes six are so provided, but only in *Ateles* does the number attain eight. With the same exceptions, again, the first four caudal vertebræ unite by articular processes, while transverse processes (single or antero-posteriorly

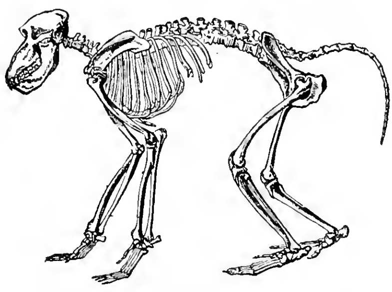

FIG. 18.—Skeleton of Chacma Baboon (*Cynocephalus porcarius*). From De Blainville.

double) exist in a great part of the tail. In *Ateles* the caudal vertebræ are (as might be expected from the very prehensile character of the tail) exceptionally provided with bony processes serving as points of muscular attachment. *Chevron bones* and processes for their attachment are altogether wanting only in the *Simiinæ* and in *Macacus inuus*. They attain their maximum in *Ateles*, where they present almost every variety of development in one or other part of the caudal region.

Certain vertebral processes, which in man are generally inconspicuous, and which are but little developed in the *Simiinæ*, attain in lower forms a marked development. These are the *metapophyses* and *anapophyses*. The first of these generally appear about the eighth or ninth dorsal vertebra, and may thence be traced backwards into the anterior caudal vertebræ, where they end by coalescing with the prezygopophyses. In *Ateles* these processes may sometimes be traced as far forward as the third cervical vertebra. The anapophyses become, below the *Simiinæ*, very conspicuous, projecting outwards and backwards from one vertebra, and embracing the prezygopophysis of the vertebra next behind. Generally they may be traced from the eighth or ninth dorsal vertebra to the penultimate lumbar vertebra. They attain their maximum of relative size in the lower *Cebidæ*. They may (as sometimes in *Ateles* and *Cynocephalus*) be traced on to the posterior cervical vertebræ, while they appear to coalesce with the transverse processes in the tail, and thus they may be developed almost throughout the vertebral column. The *Cebidæ* often develop *hyperapophyses* in the last dorsal and in the lumbar vertebræ. These processes are somewhat similar to *anapophyses*, but are placed much higher, and each pair embraces the spinous process of the vertebra next behind.

In most apes *the sternum* is quite narrow, and consists of a more or less enlarged manubrium, followed by a chain of sub-equal and antero-posteriorly elongated bones from three to six in number. In the *Simiinæ* alone do we find a broad sternum, or one consisting of a manubrium, followed by one bone only, as in *Hylobates*. The orang presents a singular peculiarity, in that the breast-bone long remains made up of ossifications arranged in pairs, side by side, successively. The total number of *ribs* has already been indicated in speaking of the dorsal vertebræ. The *true ribs* are seven in number on each side in the highest forms, but in *Hylobates* there are sometimes eight. In *Ateles* there are sometimes nine pairs. In *Hapale* the number varies from six to eight, and it is seven or eight in the other genera. The "angles" of the ribs are never so marked as in man. They are most marked in *Hylobates*. *Pithecia* is distinguished by the greater relative breadth of the ribs. In no ape is the thorax half as broad again as it is deep from back to breast. Nevertheless, in the *Simiinæ*, its transverse diameter exceeds its depth by from about one-fourth to a little under one-third of the latter. In *Ateles* (and sometimes also in *Mycetes*) the thorax is wider than it is deep, but in all the rest it is narrow, being deeper than it is wide.

The Appendicular Skeleton.

The development of this part of the skeleton has been indicated in a general manner in speaking of the external form. The length of the pelvic limb compared with the pectoral one—the foot and hand being removed—attains in no ape the proportion that it does in man, *i.e.*, 145 to 100; the nearest approximation being made by *Nyctipithecus* and *Callithrix*, namely, about 137 to 100. The length of the foot, compared with that of the hand, is exceptionally small in the *Simiinæ*, namely, from 84 up to 115 to 100. Its greatest relative length is in *Chrysothrix*, viz., about 177 to 100. In man it is about 134 to 100. The entire pectoral limb (measured from the summit of the head of the humerus to the distal end of the longest digit) is absolutely longest in the gorilla and orang. Its proportion to the spine is greatest in *Hylobates*, where it may attain the proportion of 222 to 100. Next come *Ateles* 174, *Simia* 170, the gorilla 150, and the chimpanzee 152. The rest vary from 121 to a little shorter than the spine, except certain of the lower *Cebidæ*, thus in *Chrysothrix* and *Hapale* it is less than 84 to 100. Only in the *Simiinæ* and in *Ateles* is the pectoral limb, without the hand, shorter than the spine.

The *scapula* of the gorilla presents a remarkable likeness to that of man, but that of its congener, the chimpanzee (the posterior vertebral angle being so acute), is less like man's than is that of the orang. The size of the supra-spinous fossa, as compared with the infra-spinous one, attains its maximum in the gorilla and *Mycetes*. In *Simia* and the *Pitheciinæ* the supra-spinous fossa is exceptionally small. The margin, corresponding with the superior margin of man's scapula, is generally convex in the forms below the *Simiinæ* (except *Ateles* and *Pithecia*), and attains its maximum of convexity in aged *Cynocephali*. A suprascapular notch is not well defined in the great majority of the *Simiadæ*, but in some of the *Cebidæ* (*Ateles* and *Mycetes*) it is constantly, and in others often, so enclosed as to become a foramen. In *Mycetes* a remarkable flat process springs from the bridge of bone encircling this foramen. This process exists in no other genus. The surface for the *teres major* muscle projects out very strongly in the *Cynopithecinæ* and in *Cebus* and *Chrysothrix*. The *acromion* and *coracoid processes* are short in the lower *Simiadæ;* both are long in the *Simiinæ* and in *Ateles*.

The *clavicle* is well developed in every species of the order, and that of the orang is absolutely the largest; and it is longest, compared with the spine, in that animal and in *Hylobates*, being as 28 or 32 to 100, while in the lower *Cebidæ* it may be less than 12 to 100. This bone is exceptionally slender in *Mycetes*, and is broadest in *Troglodytes* and the *Cynopithecinæ*. In the lower *Simiadæ* a fossa is excavated beneath the acromial end of the bone. Rarely, as in *Simia*, there is a very prominent deltoidal ridge.

The *humerus* presents in all apes the same fossæ and prominences as in man. Its length, as compared with the spine, is in *Hylobates* 70 or 80 to 100; but in most apes its length, thus compared, is between 45 and 30 to 100. The articular surface of the head is directed backwards and inwards, instead of almost exclusively inwards, as in man. In this respect man is most resembled by the *Simiinæ*. The tuberosities may project upwards slightly above the articular head, as in *Cynocephalus*. Generally they are about on a level with its top, but may be decidedly below it, as in *Ateles*, *Hylobates*, and *Simia*. The radial border of the bicipital groove may be very prominent, as in *Cynocephalus*. The groove may be spanned by a bridge of bone, as sometimes in the chimpanzee. The position of the nutrient foramen varies even in different individuals. The supinator ridge is especially developed in *Cynocephalus*, *Cebus*, and *Hapale*. In the *Simiinæ* it is only slightly developed. The external condyle is distinct in the *Simiinæ;* in the other genera it is closely applied to the capitellum. A supra-condyloid foramen is never present normally in the *Simiadæ*, but is present more or less constantly in the *Cebidæ*, from *Cebus* downwards, being perhaps most frequently absent in *Hapale*. Through this canal the brachial artery and median nerve pass. The projection of the radial margin of the trochlea is most prominent in the *Simiinæ* and *Hapale*. It almost disappears in the *Cynopithecinæ*. The *radius* and *ulna* are never ankylosed together in apes. They diverge most, medianly, one from another in the gorilla. The radius is four-fifths the length of the spine in *Hylobates*, and three-fifths in *Simia* and *Ateles*. Mostly it is between three-tenths and two-fifths of the length of the spine, but may, as in *Hapale*, be only a quarter. The total length of the radius rather more frequently falls short of, than exceeds, that of the humerus. It exceeds it in *Simia*, *Hylobates*, *Ateles*, *Cynocephalus*, and sometimes in the *Semnopithecinæ*. In all the others it falls short—in none, however, so much so as in man, *Brachyurus* approximating most to the human proportion. The radius is stoutest in *Cynocephalus*, slenderest in *Ateles*, and, above all, in *Hylobates*. The ulna varies, like the radius, in length and breadth. The olecranon is broad in the *Simiinæ*, but in the lower apes it is relatively larger, especially in *Cynocephalus* and *Mycetes*. The styloid process is very long in *Hylobates*, where it develops a prominence, on its hinder side, for the internal lateral ligament of the wrist. In *Ateles* this process is extremely long, having, as it were, a rounded articular head placed at the end of a peduncle. The ulna articulates with the carpus in all the apes except *Troglodytes* and *Simia*.

The skeleton of the *hand* attains its greatest bulk in the gorilla, but its greatest length in the orang. It may be more than half the length of the spine in *Hylobates*, and hardly less in *Simia* and *Ateles*. It may be but a fifth, as in *Chrysothrix*.

The *carpus* consists, in *Troglodytes*, of the same eight bones as in man. In all the other genera there is a ninth bone, the *intermedium*. Only in *Hylobates* does the length of the carpus considerably exceed its breadth—as 100 to 82. The nearest approach to this is made by *Ateles*, where the length is to the breadth as 100 to 107. The *scaphoides* may, as in the gorilla and lower *Simiadæ*, develop a large tuberosity. The *intermedium* has a flattened proximal surface, which joins the ulnar part of the concave distal articular surface of the scaphoides. Its distal surface is in general deeply concave antero-posteriorly, and embraces the radial side of the head of the magnum. The bone appears to answer to part of the scaphoid of man. The *cuneiforme*, except in *Troglodytes* and *Simia*, articulates directly with the ulna. The *pisiforme* is small (as in man) in *Simia* and *Ateles;* it is very large in the gorilla and *Cynocephalus*, and long but slender in *Hylobates*. Commonly it contributes to form, with the cuneiforme, a cup for the reception of the end of the styloid process of the ulna. The *trapezium* has sometimes, as, *e.g.*, in the gorilla and *Hylobates*, a very large radial tuberosity. The surface for the reception of the first metacarpal is convex from the dorsal to the palmar surface of the bone, and sometimes it is more or less concave in the reverse direction, but this concavity is never so strongly marked as in man. In the highest apes there appears to be much irregularity as to its development. In *Hylobates* there is no trace of any concavity, but a strongly convex and rounded tubercle receives the articular cup of the base of the first metacarpal. In the lower *Simiadæ* the concavity is sometimes present, and sometimes in the *Cebidæ* (as, *e.g.*, occasionally in *Cebus* and *Brachyurus*) a small saddle-shaped surface may be found. In *Ateles* the trapezium is large in spite of the rudimentary condition of the pollex, but there is no saddle. The trapezium is always so placed that the axis of the convexity of the saddle forms a marked angle with a line drawn across the articulations of the four outer metacarpal bones with the proximal row of carpals. In the gorilla this angle is, as in man, very open; but in the chimpanzee and lower *Simiadæ* it is smaller, the trapezium being, as it were, somewhat more pressed inwards, at its radial end, towards the middle of the palm. In the American apes the trapezium is well set out; and this, no doubt, contributes to produce that very feeble opposition and palmad flexion of the pollex which have been noticed as existing in them. The *magnum* is not generally the largest carpal bone, but rather the unciforme, which latter has its palmar process sometimes very much produced, as is the case in *Hylobates*. The *metacarpus* attains its greatest absolute length in the third metacarpal of *Simia*. This segment may, as in *Hylobates*, attain the proportion of one-fifth the length of the spine. The metacarpals are longer and narrower proportionally in apes than in man.

The *phalanges* are the same in number in apes as they are in man, except that in *Ateles* and *Colobus* the pollex may have but one small nodular phalanx or none. The phalanges are generally more curved than in man, and, except in the *Hapalinæ*, the ultimate phalanges are always flattened from dorsum to palm. In the *Hapalinæ* they are laterally compressed, curved, and pointed to support the peculiar claws of that sub-family. The length of the pollex with its metacarpal bears a much greater proportion to that of the spine in *Hylobates* and *Simia* than in man. With the exception of *Ateles* and *Colobus*, the shortest thumb, thus estimated, is found in *Nyctipithecus* and *Chrysothrix*, namely, 11 to 100.

The pollex without its metacarpal, compared in length with the manus, is shortest (viz., as 17 to 100) in *Hylobates*, and longest (viz., as 32 to 100) in *Hapale*. The pollex, when brought beside the index digit, rarely extends so far as in man, and does so only in the *Cebidæ*, where, in the *Hapalinæ*, it may reach nearly to the distal end of the proximal phalanx of the index. In *Cynocephalus* it may reach the middle of that phalanx, while in

Troglodytes it reaches but very little beyond its proximal end.

The entire *pelvic limb*, measured from the summit of the femur to the distal end of the longest digit, is absolutely greatest in the gorilla, and then in the orang and the chimpanzee. If the pes be removed, then the leg of the chimpanzee is longer than that of the orang.

Compared with the length of the spine, the entire pelvic limbs of *Hylobates* and *Ateles* are longest, namely, as 162 or 169 to 100. That of *Hapale* is the shortest, being but as 110 to 100. Without the pes, the leg of *Hapale* is also shortest relatively compared with the spine, namely, as 77 to 100; while that of *Hylobates* is longest, namely, as 125 to 100. The *os innominatum* is in every species strikingly different in form from that of man. In absolute size this bone attains its maximum in the gorilla, where it is much larger than in man, and where the ilium is very broad. The external surface of the ilium is generally more or less concave, and concave only. In *Troglodytes* and *Simia*, however, it is more or less convex, but not as in man, and therefore there is no sigmoid curvature of the crest of the ilium, and there are no distinct gluteal lines. The internal surface of the ilium is generally narrow and flat, or only slightly concave, except in the gorilla. The tuberosity of the ischium is always a marked and more or less rugose enlargement of the bone; but in the *Simiadæ* below *Troglodytes* it is flattened and very much developed, and so much everted that sometimes (in *Cynocephalus*) its transverse exceeds its antero-posterior diameter. In the *Cebidæ* it again becomes small, and more or less rounded.

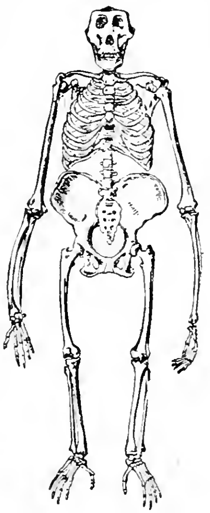

FIG. 19.—Skeleton of the Gorilla (*Troglodytes gorilla*). From De Blainville.

The spine of the ischium is generally very small, yet distinct. Only in *Simia* does it attain a considerable sharpness and prominence. The great sciatic notch is never very deep and concave, as in man. It is most concave in the gorilla, the orang, and in *Cynocephalus*. The lesser sciatic notch is generally represented by a margin which is so slightly concave as to be almost or quite straight save through the eversion of the tuberosity. The projection of the spine of the ischium produces in man a deep notch such as exists in no ape. The cotyloid notch, and the excavation continuous with it, are constantly present, even in *Simia*, where, however, it is very small and narrow, in harmony with the absence of the *ligamentum teres*.

The *femur's* length, compared with that of the spine, is as 67 to 100 in *Hylobates*, 61 in *Ateles*, 54 in the gorilla, 47 in *Simia*. It is shortest in *Chrysothrix*, 40, and *Hapale*, 37. In the *Simiinæ* it is shorter than is the humerus, its proportion to which in *Simia* is as 73 to 100. Only in some of the *Semnopithecinæ* does its length exceed that of the humerus more than it does in man. The shaft of the femur is sometimes nearly straight, as in *Hylobates* and in most *Cebidæ*. The femur is stoutest, relatively as well as absolutely, in the gorilla. It is slenderest in *Hylobates*. The neck of the femur is longest in *Simia* and *Hylobates;* shortest in *Hapale*. Except in the *Simiinæ* and in *Mycetes*, the great trochanter is pointed at its upper end. The trochanteric fossa is shallow in the gorilla, but is in most forms deep. The lesser trochanter is at its minimum of relative size in the *Simiinæ*, and is largest relatively in *Hapale*, and the posterior surface of the femur is in that genus wide and flat between the trochanters. The pit for the insertion of the *ligamentum teres* is always present, except in the orang and gorilla, where it is absent almost constantly in the first ape, occasionally in the second. In the *Simiinæ*, *Ateles*, and *Lagothrix* the internal condyle projects considerably further backwards than does the external one. The angle formed by the neck of the femur with the shaft varies from about 155° (*Simia*) to 128° (the gorilla).

The *tibia* and *fibula* never become ankylosed together. The tibia is absolutely longest in the gorilla. Its length, compared with that of the spine, is never so great as in man, except in *Hylobates*, in which it is slightly longer relatively. It is shortest in *Mycetes*, about as 37 to 100. Its length is generally less than that of the femur, but sometimes, in *Hapale*, it slightly exceeds it. It is never, however, so short compared with the femur as in man. The crest of the tibia is not so sharp as in man. The shaft is sometimes straight, as in *Lagothrix* and *Pithecia*, sometimes considerably curved, as in the gorilla and lower *Cebidæ*. The malleolus is generally well-developed, but sometimes, as in the orang, very short. Its articular surface is sometimes nearly at right angles with the inferior surface of the shaft of the tibia, as in the chimpanzee; sometimes it forms an obtuse angle with that surface, as in the gorilla, and still more in the orang. The distal articular surface of the shaft of the tibia is rarely horizontal, as in *Ateles* and *Lagothrix*. In the *Simiadæ* and lower *Cebidæ* the outer portion rises so that the articular surface slopes upwards and peronead. The fibula has its malleolus much produced outwards, projecting only about as much as, or rather less than, the tibial malleolus, whereas in man the fibular malleolus is much deeper than the tibial one.

The length of the *pes* (or foot) is absolutely greatest in the orang and gorilla. Estimating the spine as 100, the length of the pes is as much as 53 in the orang; it approximates to man (35 to 100) most in the lowest *Simiadæ*, and in *Chrysothrix*—36 to 100. The proportional length of the pes to the rest of the pelvic limb is greatest in *Simia* (58 to 100), then in *Nyctipithecus* and *Hapale* (50 to 100), but never falling quite so low as in man, where it is 30 to 100. Its length, as compared with that of the tibia, is greatest in *Simia* (122 to 100). In all the rest it is more than four-fifths, except sometimes in *Hylobates*, which however is never so small as in man, *i.e.*, as 67 to 100. The length of the pes, compared with that of the manus, is greatest in *Chrysothrix* (177 to 100). In *Ateles* it sinks to 113 to 100, and in *Hylobates* to 85 or 84 to 100.

The absolute length of the *tarsus* is never so great as in man, though that of the gorilla is nearly as long. The rest of the foot is so much longer relatively in apes than in man, that, whereas in him the proportion of the tarsus to the whole pes is as about 46 to 100, it is only 39 to 100 in the gorilla, which in this respect approaches nearest to man. The proportion sinks to 26 to 100 in *Simia* and *Ateles*, and 27 or 28 to 100 in *Hylobates*. Only in *Simia* and *Hylobates* is the tarsus ever less, or only a very little more, than twice the length of the carpus. The tarsus consists constantly of the same seven bones as in man, and these bones are so arranged, or bound together by ligaments, as to form a transverse and an antero-posterior arch. In no ape, however, do the distal ends of the inner metatarsals form the anterior point of support of the antero-posterior arch, as in man. The *os calcis* is always, except in the gorilla, shorter compared with the spine than in man. The *tuberosity* may be produced upwards or downwards, or both, and is concave or grooved behind, except in the gorilla. In no ape are the long axis of the heel or the peroneal and tibial surfaces of the os calcis so vertical as they are in man; but the bone is always more or less twisted, so that the *sustentaculum tali* forms a more or less acute angle with the long axis of the tuberosity instead of a right angle, as in man. The twisting of the os calcis is very slight in *Simia* and *Pithecia*, and not great in *Ateles* and *Hylobates*. It is more marked in the lower *Simiadæ*, and more so still in *Troglodytes*. A narrowing of that part, which answers to the plantar surface of man, accompanies this in-twisting. In the gorilla that part of the os calcis which is behind the articular surface for the astragalus exceeds in length all the bone anterior to the hinder border of that surface; and in this respect the gorilla may be said to have the longest heel of any ape, and a longer heel than man. The head of the *astragalus* is generally united to its body by a tolerably long neck. This neck is, however, in the gorilla shorter than even in man. The upper surface of this bone is less convex than in man, in *Simia*, *Ateles*, and the gorilla; generally it is more convex than in man. The surface for the external malleolus forms, with the upper surface of the astragalus, almost a right angle in *Hylobates* (as in man), and an obtuse one in *Ateles* and *Lagothrix*. In most other apes (including *Troglodytes*) it forms an acute angle. The angle formed by the upper surface of the astragalus with that for the tibial malleolus, instead of being a right angle, as in man, is generally more or less obtuse, especially in the gorilla. The *naviculare* has sometimes its tuberosity greatly developed; this is especially the case in *Hylobates*. The surfaces for the three cuneiform bones are generally more convex and concave respectively than in man. The *ento-cuneiforme* generally has its plantar and distal surfaces considerably longer than its dorsal and proximal surfaces respectively. These are exceptionally equal (as in man) in the orang and gorilla. The surface for the hallux is always strongly convex. The long axis of this articular surface always forms a more or less acute angle with a line drawn across the articular surfaces for the four outer metatarsals. In the lower *Simiadæ* this angle is as acute as in man. In *Troglodytes* it is a little more open, but not nearly so open as is the homotypal angle in the hand even of the same species. The surface is never saddle-shaped in apes. In all apes, even in the chimpanzee, the distal tarsal segment is capable, as a whole, of a considerable degree of motion upon the proximal part,—*i.e.*, upon the astragalus and os calcis,—and this mobility is extreme in the orang. The absolutely longest *metatarsal* bone is the second of *Simia*. The metatarsus often exceeds the tarsus in length, but it may, as in the gorilla, fall much short of it, thus resembling man. The four outer metatarsals and the innermost one diverge instead of being parallel, as in man. The former, except in the *Simiinæ* and in *Ateles*, are more rounded than in man, and their distal articular surfaces are less bent downwards, and are limited posteriorly by a deeper transverse groove. The first metatarsal, compared in length with the spine, is longest in *Hylobates* (10 or 12 to 100), and shortest in *Hapale* (about 6 to 100). It is always longer than the first metacarpal, except in *Simia*. Its proximal surface is generally more concave than in man, and its long axis is different. It is as if the metatarsal of man had been removed, softened, and then, after being turned, so that the dorsum looks inwards as well as upwards, reapplied to the convex ento-cuneiforme, and thus stamped with an oblique depression. The angle formed by this surface, with a line traversing the articular heads of the four outer metatarsals, approximates to a rectangle instead of to a straight line, as in man.

The *phalanges* are always the same in number as in man, except that the hallux of *Simia* has often but one. They are very like their homotypes in the manus, and are convex above, concave and flattened below. Only in the *Hapalinæ* are the last phalanges laterally compressed instead of flattened. The pedal digits are never nearly so short relatively in apes as they are in man; yet the proportion borne by the hallux, with its metatarsal, to the spine closely approximates in the gorilla to the proportion existing in man, and the proportion is exceeded in *Hylobates* and *Ateles*. It is much in defect in *Hapalinæ*, where it is little more than one-tenth. Its proportion to the whole pes in *Hylobates* (as in man) is nearly half, while in *Simia* it is but a quarter, and but little more in the *Hapalinæ* and the *Semnopithecinæ*. The hallux, when brought beside the second digit, never reaches so far as in man, but at most (as in the chimpanzee) to the proximal end of the second phalanx, or to the middle of the proximal phalanx (as in most *Cebidæ*), or a little beyond its base (as in *Hapale* and the *Semnopithecinæ*), or not nearly even to the distal end of the metatarsal (as in *Simia*). Except in *Simia* and some *Cebidæ*, notably *Hapale*, the hallux projects further than does the pollex of the same individual when applied to the second digit of the manus. The hallux also always exceeds the pollex in absolute length, except in *Hapale* and *Simia*. The length of the hallux, without its metatarsal, compared with that of the spine, is as 25 to 100 in the chimpanzee (as in man), 19 in the gorilla, and but 8 in *Simia*. The second digit of the pes is always longer than that of the manus except in the *Simiinæ*, which so far resemble man. The index digit, with its metatarsal, compared with the spine, is as 38 to 100 in *Simia*, and it varies thence down to 21 in *Cercopithecus*. The longest digit of the pes always exceeds that of the manus, except in the *Simiinæ* and *Ateles*.

The Muscles.

The muscles of apes are very similar in number, distribution, and form to those of man, except that in the long-tailed forms (*e.g.*, *Semnopithecus*) the muscular bundles answering to the coccygeal muscles of man are so greatly developed as to form eight sets of caudal muscles. The *latissimus dorsi* commonly sends on a slip, called the *dorso-epitrochlear*, as far as the olecranon. Often there is a *rhomboideus capitis*, and a muscle, called *levator claviculæ*, almost always descends from the cervical transverse processes to the outer part of the clavicle. The *flexor longus pollicis* and the *flexor digitorum profundus* are always more or less united. The *extensor indicis* commonly sends a tendon to the third digit as well as to the index, and at the same time the *extensor minimi digiti* sends a tendon to the fourth digit as well as to the fifth. An *extensor primi internodii pollicis* is never developed, but the *extensor ossis metacarpi pollicis* is often doubled, even in the chimpanzee. In the orang the *flexor longus pollicis* sends a tendon only to the index. In *Hylobates* the *supinator longus* is inserted into the middle of the radius, and there is an *abductor tertii internodii indicis* going from the metacarpal of the index to its ungual phalanx. Often the *extensor brevis pollicis* and the *abductor longus* become more or less united. In spite of the rudimentary condition of the thumb in *Ateles*, its muscles exist, though in a rudimentary condition, but in *Hapale* the *opponens pollicis* is wanting.

The lower limb in the orang generally wants the *ligamentum teres*, which seems to be sometimes absent in the gorilla also. The *glutæi* muscles of apes are feeble and small, and are inserted low down on the femur. Only in the gorilla are they large enough to cause a small buttock to protrude over the ischiatic tuberosities, but even in this ape the buttocks do not meet so as to conceal the anus. Apes have an extra muscle, called the *scansorius*, which passes down from the edge of the ilium to the great trochanter of the femur, and must act as a powerful rotator of the thigh inwards The *gracilis* is much broader than in man, and is inserted lower down on the tibia than in him, as is also the case with the *semi-membranosus* and *semi-tendinosus*. The short head of the *biceps femoris* is generally wanting. The *gastrocnemei* and *soleus* are flatter than in man, and the latter has only a fibular origin. In the lower *Simiadæ* the *plantaris* passes over the pulley-like end of the os calcis, and goes to the plantar fascia. No ape seems to have any *peroneus tertius*, but we may find even in *Semnopithecus* a slender *peroneus quinti digiti* passing behind the outer malleolus, and going to the metatarsal of the fifth digit, while in the *Cebidæ* we may also have a *peroneus quarti digiti* going similarly to the fourth digit. The *tibialis anticus* may be divided, as even in the chimpanzee, like its homotype the *extensor ossis metacarpi pollicis*. The muscles of the foot, with the exception of the *interossei*, resemble the muscles of the foot of man, and not those of his hand. As regards the *interossei* even, the difference is very slight. It consists in the insertion of the tendon of that dorsal interosseous mass which is interposed between the second and third metatarsals, into the proximal phalanx of the third digit (as in the human hand), instead of into that of the second digit (as in the human foot). The hallux in the orang is, in spite of its imperfect development, provided with an *opponens* muscle. The *flexor brevis digitorum pedis* does not, in apes, arise exclusively from the os calcis, and the *flexor accessorius* arises from the surface of the deep flexor tendons. The last named muscle may be wanting, as sometimes at least in *Hylobates*. A muscle, called the *abductor ossis metacarpi quinti*, exists even in the chimpanzee. In the lower *Cebidæ*, and especially in the *Hapalinæ*, the interossei become true *flexores breves*, and altogether cease to be visible on the dorsum of the foot.

The Brain.

The absolute size of the brain never in any ape approaches that of man. Thus the cranial capacity is never less than 55 cubic inches in any normal human subject, while in the orang and chimpanzee it is but 26 and 27½ cubic inches respectively. The relative size of the brain varies inversely with the size of the whole body, but this is the case in warm-blooded vertebrates generally. The extreme length of the cerebrum never exceeds, as it does in man, two and a quarter times the length of the basi-cranial axis. The proportion borne by the brain to its nerves is less in the apes than in man, as also is that borne by the cerebrum to the cerebellum. In general structure and form the brain of apes greatly resembles that of man. Each half of the cerebrum contains a triradiate lateral ventricle, and though in some *Simiadæ* the posterior cornu is relatively shorter than in man, it again becomes elongated in the *Cebidæ*, and in many of the latter it is actually longer relatively than it is in man. The posterior lobes of the cerebrum are almost always so much developed as to cover over the cerebellum, the only exceptions are the strangely different forms, *Mycetes* and *Hylobates syndactylus*. In the latter the cerebellum is slightly uncovered, but it is so considerably in the former. In *Chrysothrix* the posterior lobes are much more largely developed relatively than they are in man. The cerebrum has almost always a convoluted external surface. In this group, however, as in mammals generally, a much-convoluted cerebrum is correlated with a considerable absolute bulk of body. Thus in *Hapale* (and there only) we find the cerebrum quite smooth, the only groove being that which represents the Sylvian fissure. In *Simia* and *Troglodytes*, on the contrary, it is very richly convoluted. A *hippocampus minor* is present in all apes, and in some of the *Cebidæ* it is much larger relatively than it is in man, and is absolutely larger than the *hippocampus major*. Of all apes, the orang has the brain which is most like that of man; indeed, it may be said to be like man's in all respects, save that it is much inferior in size and weight, and that the cerebrum is more symmetrically convoluted and less complicated with secondary and tertiary convolutions. If the brain of *Simia* be compared with that of *Troglodytes*, we find the height of the cerebrum in front greater in proportion in the former than in the latter; also the "bridging convolutions," though small, are still distinguishable, while they are absent in the chimpanzee. Nevertheless, this character cannot be of much importance, since it reappears in *Ateles*, while two kinds of the genus *Cebus* (so closely allied as to have been sometimes treated as one species) differ strangely from each other in this respect. The *corpus callosum*, in apes generally, does not extend so far back as in man, and it is very short in *Pithecia*. In the orang and chimpanzee there are, as in man, two *corpora albicantia*, while in the lower monkeys there is but one. The *vermis* of the cerebellum is larger in the *Cebidæ* than in the *Simiadæ*. In all apes below the *Simiinæ*, each lateral lobe of the cerebellum gives off a small lobule, which is received into a special fossa of the petrous bone. Certain prominences of the *medulla oblongata*, termed *corpora trapezoidea*, which are found in lower mammals, begin to make their appearance in the *Cebidæ*.

The Teeth.

The teeth, of apes consist, as in man, of incisors, canines, premolars, and molars; but the series of teeth nowhere forms so perfect an arch as in man, the opposite series of grinding teeth tending to become more parallel. No ape has the teeth placed in one uninterrupted series in each jaw, as is the case in the human species, but there is always a small interval (*diastema*) between each upper canine and the adjacent incisor, and between each lower canine and the adjacent premolar. This condition is due to the excessive size of the canines, the interspaces giving passage to the apices of these teeth. This prolongation of the canines into tusk-like weapons of offence and defence (especially developed in the males), makes a great difference between the aspect of the dentition in apes and man. The number of the teeth is the same as in man in the *Simiadæ*. The *Cebidæ* have an additional premolar on each side of each jaw, and the *Hapalinæ*, besides this, have a true molar the less. The incisors are always nearly vertical, save in the *Pithecinæ*, when their apices project strongly forward. The canines are always considerably longer than the incisors, except in the genus *Hapale*, where the lower incisors equal the canines in length. The premolars differ structurally from the molars much as in man, save that the first lower premolar may be modified in shape to give passage to the upper canine, as is specially to be seen in *Cynocephalus*. The grinding surface of the molars consists generally of two transverse ridges, each end of each ridge projecting more than the intermediate part, and so giving rise to four tubercles. In *Simia* and *Troglodytes*, however, we find in the upper molars an additional structure, which also exists in man. This is a ridge which runs obliquely from the front inner tubercle (or cusp), outwards and backwards to the hind outer tubercle. In the rest of the *Simiadæ* this ridge is wanting, but it reappears in *Ateles* and *Mycetes* amongst the *Cebidæ*. In the *Hapalinæ* the tubercles of the molars are more produced and sharp-pointed, in harmony with their decidedly insectivorous habits. The last lower molar may be reduced or much enlarged as compared with the others. Thus in *Cercopithecus talapoin* it has but three tubercles, while in the *Macaci* and *Cynocephali* it is very large, and has five well-developed cusps. The number of milk teeth is as in man, save that the *Cebidæ* have an additional milk molar. In general the canines are the last teeth to be cut of the permanent dentition. Their cutting sometimes causes such constitutional disturbance as to produce convulsions and death. In the gibbons, however, the canines accompany, if they do not precede, the appearance of the hindmost molar, while in the orang they at least sometimes make their appearance before that grinder.

Organs of Nutrition and Excretion.

The alimentary, circulating, and excretory organs of apes closely resemble those of man. The mouth is always guarded by *lips*, which, though generally thin, are often very mobile and extensible, the lower lip having no frænum in the orang, and this is also absent in *Cebus*, though it may be present in other forms, as, *e.g.*, in *Troglodytes* and *Cynocephalus*.

The *tongue* is much longer relatively in most apes than in man; but it may closely resemble his, as does that of the orang, in which the circumvallate papillæ are collected in a V-shaped aggregation, while there may be only two such papillæ, as in *Cynocephalus* and *Ateles*. In *Hylobates* the tongue is in this respect man-like; yet in that genus we first meet with a *sub-lingual process* (which becomes much larger in the lower apes), in the form of a little conical bifid membrane. This structure is formed by the union of the processes upon which open the sub-maxillary ducts—processes much elongated in the chimpanzee, though man-like in the orang.

The *uvula* is generally present, but becomes rudimentary in the *Cebidæ* generally, though it exists as a relatively thick, short structure in *Hapale*. It is long and pointed in *Semnopithecus*, and plainly visible in *Hylobates* and *Troglodytes*. On the other hand, in *Simia* it is disguised by the extensive development of the membranous edge of the *velum palati* on each side of it.

The *stomach* is simple in all the apes except the *Semnopithecinæ*. It is especially human in shape in *Hylobates*, except that the pylorus is somewhat more elongated and distinct. It is of a rounded form in *Pithecia*, and in *Hapale* the cardiac orifice is exceptionally near to the pylorus. In the *Semnopithecinæ* the stomach is extremely sacculated, especially at the cardiac end, being, in fact, very like a colon spirally coiled. It is in the stomach of these apes that the oriental Bezoar stones are found.

The *intestine* in apes is devoid of *valvulæ conniventes*, but is always provided with a well-developed *cæcum*, though it is short and conical in *Cynocephalus*. Only in the *Simiinæ* do we find a *vermiform appendix*.

The *colon* may be much longer relatively than in man, as in *Simia* and *Troglodytes*. It may be greatly sacculated, as in *Hylobates*; or devoid of sacculations, as in *Cebus*. As in fœtal man, so in the lower apes, only the right extremity of the mesocolon is involved in the formation of the great omentum, the middle and left parts of the mesocolon lying behind, and independent of the omentum. This is not, however, the case in the *Simiinæ*, which are more like adult man in this respect.

The *liver* may be very like man's, especially in *Hylobates*, the orang, and the chimpanzee; but in the gorilla both the right and left lobes are cleft by a fissure almost as much as in *Cynocephalus*. In the *Semnopithecinæ* the liver is much divided, and it is placed obliquely to accommodate the sacculated stomach. The lateral lobes of the liver are in *Hapale* very much larger than the central lobe. The *caudate lobe* is very large in the *Cebidæ*, especially in *Ateles*, and above all in *Pithecia*. There is always a gall-bladder.

The *larynx* is in many apes furnished with sac-like appendages. These are different in different species as regards number, size, and situation. They may be dilatations of the laryngeal ventricle (opening into the larynx below the false vocal chords), as in *Simia* and *Troglodytes*. They may open above the false vocal chords so as to be, in fact, extensions of the thyro-hyoid membrane, as in *Hylobates*. There may be but a single median opening in the front part of that membrane at the base of the epiglottis, as in the *Simiadæ* below the *Simiinæ*. There may be a single median opening at the back of the trachea, just below the cricoid cartilage, as in *Ateles*. There may be but a single sac, or there may be five, as sometimes in *Mycetes*. These may be enormous, meeting in the middle line in front, and extending down to the axillæ, as in the gorilla and orang. A sac may occupy the cavity of the expanded body of the hyoid bone, as in *Mycetes*.

The *os hyoides* has its basilar part generally somewhat more convex and enlarged than in man; but in *Mycetes* it becomes greatly enlarged and deeply excavated, so as to form a great bony bladder-like structure.

The cornua of the hyoid are never entirely absent, but the anterior or lesser cornua may be so, as in *Mycetes*. The anterior cornua never exceed the posterior cornua in length; but they may be (*e.g.*, in *Cercopithecus*) more largely developed relatively than in man, and they may even be jointed structures, as in *Lagothrix*.

The *lungs* have generally the form of those of man; but the right lung may have four lobes, as, *e.g.*, in *Hylobates*.

The great *arterial trunks* in *Simia* and *Troglodytes* are arranged as in man. In *Hylobates* and the lower apes, however, the left carotid may take its origin from the innominate artery.

The Generative Organs.

The generative organs are, in common with the other parts of the body, formed on the same model as in the human species. The *penis* is pendulous, *i.e.*, hangs freely, instead of being (as in the dog) bound to the ventral surface of the abdomen. The prepuce, however, is without a frænum. The *testes* are relatively large, and descend into a scrotum. In some species, however, they do not descend so much as they do in man, but remain just outside the inguinal ring, and are thus placed rather beside than beneath the penis. These parts, as has been said, are brightly coloured in some of the lower *Simiadæ*. The penis is furnished with a *bone* in all the apes below the Anthropoid ones, and probably in the latter also, since the chimpanzee has one about one-third of an inch long and gristly at each end. In all apes the *uterus* is single, and not two-horned; but it is more elongated relatively in monkeys than in the human species. The *clitoris* is well-developed, but boneless in the *Simiadæ*, and is large even in *Troglodytes niger*. In the *Cebidæ* it contains a bone; and in some genera, especially in the *Cebinæ*, it is enormously developed, so as to be very easily mistaken for a penis. In *Ateles*, however, its length is mainly due to its extremely elongated prepuce.

The *placenta* of apes is discoidal and deciduate, and is generally bilobed. Sometimes, however, as in *Mycetes*, it is single. It is especially thick in proportion in the *Hapalinæ*. In the *Simiadæ* there is but one umbilical vein, but in the *Cebidæ* there are two.

Gestation in the lower *Simiadæ* lasts about seven months, but in the *Hapalinæ* only three months.

Menstruation occurs periodically, but the excretion is less sanguineous than in the human species. In the lower *Simiadæ* it is chiefly manifested by a turgescence of the external organs, which may extend widely in the parts adjacent, and even beneath the tail.

Lactation lasts, in the better known forms, for an average of six months, and the young are carried at the breast in a very human attitude.

DISTRIBUTION IN TIME.

There appears as yet to be no evidence of the existence of apes earlier than during the Miocene period. This absence of evidence must by no means be taken as a conclusive proof of their non-existence, since, as Dr Falconer has pointed out, we ought not to expect to find ape fossils often. We ought not to expect this, because the agility and arboreal life of these animals enable them to escape local inundations, and other causes of destruction and speedy burial, to which more sluggish and terrestrial animals are exposed. When they fall dead they are almost immediately devoured by carnivorous animals and feeders on carrion, and it is owing to this that their remains are so rarely found in India, on which account the Hindoos believe that they bury their dead.

Two teeth found in Suffolk were at first described by Professor Owen as those of apes, under the title *Macacus eocænus*. This opinion, however, he has since withdrawn.[1]

A fragment of a right maxilla, from Soleure in Switzerland, was described by Rutimeyer in 1862, under the name *Cœnopithecus lemuroides*. But the recent discovery of fossil lemurs in France renders the ape character of this fragment (which was always doubtful) still more uncertain.

When we enter upon Miocene deposits we find plentiful and unquestionable remains of apes now extinct. In India, in the Sewalik hills, the astragalus of a *Semnopithecus* (resembling *S. entellus*) has been found. Also jaws and teeth of other forms allied to *Semnopithecus* and *Macacus* have been discovered, one with an upper jaw nearly as large as that of the existing orang. These fossils, however, exhibit no remarkable difference in form from the bones of existing apes.

In Europe a very remarkable ape fossil, named *Dryopithecus fontani* (Lartet), has been found at Saint Gaudens in France. A lower jaw and humerus were there obtained, but isolated teeth have also been met with in the Suabian Alps. This creature was an ape belonging to the highest sub-family, *Simiinæ*, and was allied to *Hylobates*, but of greater bulk than any existing gibbon.

Two other species of ape have been found allied to *Hylobates*, but of smaller size than *Dryopithecus*, and showing some probable affinity to *Semnopithecus*. These are *Pliopithecus antiquus* (Lartet), and *P. platyodon* (Biedermann). Of the former, two imperfect lower jaws were found in fresh-water deposit at Sansan, near Auch, in France, while of the latter, an upper jaw has been found in Zurich at Elgg, in the upper fresh-water Molasse there. Another ape (probably of the *Simiinæ*), of which a lower jaw has been found in the lignite bed at Monte Bamboli in Tuscany, has been named by G. M. Gervais, *Oreopithecus bambolii*.

M. Gaudry has also found a rich deposit of ape relics at Pikermi in Greece. He has sent thence to Paris parts of as many as twenty-five individuals, while other remains are preserved in Munich, and no less than five crania at Milan. These remains have been placed by Wagner in a new genus, *Mesopithecus*. They are very interesting, as showing a somewhat intermediate structure compared with living apes. The cranium and dentition bear affinity to *Semnopithecus*, but the limbs are rather those of *Macacus*.

Certain fragments found at Eppelsheim (in strata of the same geological age as the Pikermi deposits) have also been attributed to the former genus; while five mandibula, found at Steinheim in Würtemberg, have received the name, from Fraas, of *Semnopithecus grandævus*.

Amongst the rich palæontological treasures which have recently been found in the North American Miocene deposits are certain teeth and fragments, which, it has been suggested, may be those of apes. At present, however, their nature is quite problematical, though the presence of apes at that period in America would be a fact of extreme interest, if sufficient remains could be found to determine whether such apes were *Simiadæ* or *Cebidæ*, or forms intermediate between the two.

The Pliocene deposits have not yet yielded much in the way of ape remains. Some teeth from Montpellier (found in fresh-water marl) have been named *Semnopithecus Monspessulanus* by M. Gervais, while part of a lower jaw from the same locality has been called *Macacus priscus*. Other fragments of jaws, and some teeth of *Macaci*, have been found in the Val d'Arno, and are preserved at Pisa, Turin, and Florence. A single tooth from Grays, Essex, has been described by Professor Owen as *Macacus pliocænus*.

In America, besides the Miocene fragments before referred to, numerous bones of *Mycetes* and other genera have been found in the caves of Brazil. These, however, appear to be, geologically speaking, quite recent, and they closely resemble the bones of apes now living in that region.

For further details as to fossil apes, an article may be referred to (a translation from the Italian) by Major Forsyth, in the *Annals and Magazine of Natural History*, for the month of September 1872.

GEOGRAPHICAL DISTRIBUTION

The apes are, as far as is yet certainly known, at present almost confined to tropical latitudes. Their most northern limits in the Old World are Gibraltar (*Macacus inuus*), Moupin, in Thibet (*Macacus thibetanus* and *Semnopithecus roxellanæ*), and Japan (*Macacus speciosus*). In the New World the highest northern latitude certainly known to be attained is 18° or 19° (*Ateles melanochir*) in Southern Mexico, but they possibly reach even latitude 23° Father David, however, sees no reason (considering the severity of the climate of Moupin) why apes should not also be found in the mountains of Northern China, and the natives have repeatedly assured him they are to be found there. Southwards, apes are found to near the Cape of Good Hope, and the island of Timor (*Macacus cynomolgus*), in the Indian Archipelago, in the Old World, and to about 30° in Brazil and Paraguay, in the New World. As to vertical extent, a *Semnopithecus* has been seen near Simlah, at a height of 11,000 feet; Dr Hooker saw monkeys in the Himalaya at an elevation above 8000 feet; and *Semnopithecus roxellanæ* and *Macacus thibetanus* were found by Father David inhabiting the Snowy Mountains of Moupin, in Thibet, at an elevation of about 3000 metres, where frost and snow last several months. In Miocene times the ape range was more extensive—namely, to Greece, Tuscany, the South of France, Zurich, Würtemberg, and even to Essex.

Some of the localities richest in monkeys are islands, such as Ceylon, Borneo, Sumatra, and Java; and apes are also found in Trinidad, and the island of Fernando Po.

[1] *Ann. and Mag. of Nat. Hist* 1862, p 240.

There are, however, certain islands which seem eminently well suited to support an ape population, where apes, nevertheless, are conspicuous by their absence. Such are the West Indian Islands, Madagascar,[1] and New Guinea, moreover, no ape inhabits tropical Australia These facts become the more remarkable, if, as Father David suspects, apes exist in Northern China to-day Evidently it is not climate which prevents their existing in Central Europe now The continents of Africa, south of the Sahara, of Asia, south of the Himalaya, and of America, from Panama to the southern part of Brazil, are, with the islands before mentioned, the special ape regions of the existing fauna.

There is a remarkable difference between the ape population of the New and the Old World, the latter being inhabited exclusively by *Simiadæ*, the former as exclusively by the *Cebidæ*. Europe has but a single ape species, and Asia, north of the Himalaya, has but the few found in Thibet, China, and Japan. Africa, north of the Sahara, is zoologically a part of Europe, and there also *Macacus inuus* is found, which is the only African species of the genus. African apes are the chimpanzee and gorilla of the west coast, the former extending eastwards to 28° E. long.; the *Colobi* (which are, in fact, but the African form of *Semnopithecus*), the long-tailed *Cercopitheci*, including mangabeys (or white-eyelid monkeys); and, lastly, the baboons, *Cynocephali*. The genus *Cynocephalus* extends into Arabia; but that, zoologically speaking, is a part of Africa. The Asiatic regions possess the orang (*Simia*) (in Borneo and Sumatra), the long-armed apes (*Hylobates*), the *Semnopitheci*, and *Macaci*.

One form of *Macacus*, and a very peculiar one (*M. niger*), is found in the islands Batchian and Celebes; and it is a noteworthy fact that this, the most baboon-like of all the *Macaci*, should only exist in a region so extremely remote from Africa. The genus *Macacus* is the most widely spread of any existing genus—namely, from Gibraltar North Africa, Thibet, and Japan (perhaps even from Northern China), down to the island of Timor, and from the north-west of Africa in the west, to Batchian, Japan, and the Philippine Islands in the east. In ancient times this genus seems to have extended to France, and even to Essex. It is interesting to note that, in the Miocene period, the geographical range of the apes of India was much greater. Gibbon-like monkeys existed in the south of France, while forms intermediate between *Semnopithecus* and *Macacus* abounded in Greece.

In America, north of Panama, the genera as yet known to be represented are *Chrysothrix*, *Nyctipithecus*, *Cebus*, *Ateles*, *Mycetes*, and *Hapale*, in Veragua, *Nyctipithecus*, *Cebus*, *Ateles*, and *Mycetes*, in Costa Rica and Nicaragua, *Ateles* and *Mycetes*, in Guatemala; and *Ateles*, in Southern Mexico. Brazil is, of course, the headquarters of the American apes; but different portions of that vast region have a somewhat different ape fauna. Thus the genus *Eriodes* appears in South-Eastern Brazil to represent the species of *Ateles* inhabiting the more northern and western parts of the empire. Southwards, the genera *Cebus*, *Mycetes*, *Chrysothrix*, and *Callithrix* extend furthest; but they do not probably all extend to the furthest limit yet known, namely, 30° S. The species found farthest south are *Mycetes caraya*, *Cebus fatuellus*, and *Callithrix personatus*.

ZOOLOGICAL POSITION AND AFFINITIES OF APES.

By universal consent apes are placed in the highest rank of all brutes, and, excepting man, are generally taken to be the most perfect animals of the mammalian class. It may be questioned, however, whether, if the animal man had never existed, this place would be assigned them by any observing intelligence The half-apes, or lemurs, commonly placed in the same order with them, are certainly inferior mammals, and it might be contended that the perfection of the mammalian type is rather to be found in the *Felidæ* (or cat family), by reasoning analogous to that by which it might also be contended that birds (with their differentiated limbs, perfect circulating and respiratory systems, acute sense organs, complex instincts, and teachableness) are really the highest of all vertebrate animals, and represent the vertebrate type of structure carried to the highest degree of perfection yet attained

The question as to which animals are most nearly allied to apes is one by no means easy to answer Leaving man aside (whose close anatomical resemblance to apes is so obvious), it is at present extremely difficult to say what are the apes' true zoological affinities. It is to be hoped that future palæontological researches may afford us materials for tracing these out, but at present a chasm separates the apes from every other group of animals The half-apes, or lemurs, were generally considered to lead down from the apes towards the insectivora, and thence to the implacental mammals, but the differences between the apes and lemurs are so many and great, that it cannot be considered otherwise than in the highest degree improbable that (on the Evolution hypothesis) they took origin from any common root-form that was not equally the progenitor of other mammalian orders

But if the apes cannot be considered to show evidence of genetic affinity with any other mammalian order, do they constitute so homogeneous a group as to suggest the former existence of one ancient root-form common to them all? To this question it may be answered that the differences between the *Simiadæ* and *Cebidæ* are such as to render it doubtful whether they may not have had respectively quite different origins, and whether their resemblances may not have been superinduced by similarity of needs and conditions. The differences referred to are as to—(1), dentition, (2), nasal septum, (3), tail—the *Cebidæ* showing a tendency to a curled tail-end, while the *Simiadæ* never manifest any such tendency, (4), cheek pouches, (5), ischiatic callosities, (6), general form and habit of body, (7), opposability of the thumb, (8), bony *meatus auditorius externus*. All these characters, taken together, seem to make it probable that the *Cebidæ* and *Simiadæ* are not diverging offshots from some common ape parent, but that they have arisen in an independence as complete as that between the origin of either of them and the origin of the lemuroids or carnivores Possibly further discoveries in the Miocene deposits of North America will reveal to us transitional forms between the Old and the New World apes, but the existence of such forms cannot certainly as yet be affirmed. It may be asked, however, Can the genera, which possess so many points in common as *Cebus* and *Cercopithecus*, have come to resemble each other independently? To this it may be replied, that the number of similarities of structure which must have had an independent origin is so great that it is difficult to see why those of the two genera named may not also have had such an origin. As examples of such similarities of independent origin, the following structures may be referred to:—The bony covering of the temporal fossa in *Chelonia*, *Pelobates*, and *Lophiomys*; the compound tooth structure of *Orycteropus* and *Myliobatis*; the coexistence of a certain form of dentition with a saltatory habit in *Macropus* and *Macroscelides*; the presence of but eight carpal bones in *Troglodytes* and *Indris*; the course of the vertebral artery in *Auchenia* and *Myrmecophaga*; the flying membrane in certain squirrels

[1] Madagascar is the special home of the half-apes or lemurs.

and phalangers; the canines and premolars of *Canis* and *Thylacinus;* the grinders of *Peromeles* and *Urotrichus;* the external form and habit of body of *Mus*, *Sorex*, and *Antechinus;* and the peculiar dorsal shields in tortoises and certain frogs. But if some naturalists are disposed to admit that the common origin of the *Cebidæ* and *Simiadæ* may be very doubtful, can the be even sure of that of *Cercopithecus* and *Hylobates?* It has been recently suggested, that the *Artiodactyla* and the *Perissodactyla* (the even and the odd-toed ungulates) may be genetically independent (their common characters being merely adaptive, functional ones), as also with the *Balænoidea* (whales), and *Delphinoidea* (dolphins). The response of organisation to need being such as it is (structure and function manifesting themselves so simultaneously), the discrimination between genetic and adaptive characters must always be a work of extreme delicacy. In the presence of the various genealogical trees of animal descent which have been so hastily put forward of late, a judicious scepticism seems the attitude best warranted by the evidence yet obtained. If so many similar forms have arisen in mutual independence, then the affinities of the animal kingdom, or even of the mammalian class, can never be represented by the symbol of a tree. Rather, we should conceive the existence of a grove of trees, closely approximated, greatly differing in age and size, with their branches interlaced in a most complex entanglement. The great group of apes is composed of two such branches; but their relations one to another, to the other branches which represent mammalian groups, and to the trunks from which such branches diverge, are problems still awaiting solution.

There can, however, be no doubt that the *Simiadæ* and *Cebidæ* together form a most natural group, and are closely allied with man in structure. Moreover, as man is the highest animal, and, zoologically considered, differs less from even the lowest ape than such ape differs from any other animal, man and apes must be placed together in one order, which may well bear its primitive Linnean name, "*Primates.*" Whether any other animals (and, if any, what) should also be included in this order, are questions for the consideration of which the reader is referred to the heading MAMMALIA.

APELDOORN, a flourishing town in the Netherlands, in the province of Guelderland, 17 miles N. of Arnheim, with large paper-mills, and a population of upwards of 12,000. A short distance off is the Castle of Loo, the favourite residence of King William I.

APELLAS, a Greek sculptor, mentioned by Pausanias (vi. 1. 6) as the author of a group at Olympia, representing a quadriga, with the statues of a charioteer and of Cynisca, the sister of Archelaus. This group having been executed to commemorate the chariot victory gained by Cynisca at the Olympic games, 420 B.C., the date of the artist is obtained. A bronze sculptor of the same name, and probably the same person, occurs in Pliny (*Nat. Hist.*, xxxiv. 86).

APELLES, the most celebrated of ancient Greek painters. The date assigned to him by Pliny (*Nat. Hist.*, xxxv. 79) is 332 B.C., and with this agrees the fact of his having been the court painter of Alexander the Great, who it was said would allow no one else to paint his portrait, though, in point of fact, portraits of him by other artists are known (Pliny, vii. 93 and 125; Horace, *Epist.*, ii. 1, 239; Cicero, *Ad Fam.*, v. 12, 13). Apelles had worked before then for Philip, the father of Alexander, and with a career of nearly half a century, was at work after in the time of the first successors to Alexander's empire. He was born at Colophon, where it appears his father Pytheas, also a painter, resided. His first instructor was a certain Ephorus, of Ephesus, which was then the centre of the Asia Minor school of painting; the rival school being that of Sicyon in Greece proper, whither Apelles next proceeded, apparently to undergo the stricter discipline in drawing for which that school was renowned, and perhaps also, as is said (Plutarch, *Arat.*, 13), to win a share of the good fortune and fame of its leaders. He was here in the neighbourhood of Corinth, and it was probably then that he was taken by the beauty of the young Lais, on seeing her drawing water at the fountain of Peirene. Another incident, that of his having seen the notorious Phryne bathing at Eleusis, and from this conceived the design of his picture of Aphrodite Anadyomene, would also fall about this time, for the two reasons that Phryne's celebrity occurred in the period before Alexander, and that Apelles is not known to have made a second stay in that district of Greece. From Sicyon he went to the Macedonian court, and was there employed until Alexander departed on his expedition into Asia, on which the painter accompanied him as far as Ephesus, where he settled. Of the intimacy between him and his royal patron there are a number of stories, which, however, from the variety in the telling, may be without foundation in fact. According to Pliny (xxxv. 85), Alexander having betrayed ignorance by some remark about painting, was told by Apelles to be silent, lest the boys who were rubbing down colours in the studio might laugh at him. But the version of the same story given by Plutarch (*De Adul.*, 15) has, in the place of Alexander, the Megabyzos, or priest of Diana at Ephesus; while in Ælian (*Var. Hist.*, ii. 2) the story is told of Zeuxis, not of Apelles. Again, Ælian (*Var. Hist.*, ii. 3) relates, that while Alexander was inspecting a painting of a horse by Apelles, a horse neighed towards the picture, upon which the painter remarked that the horse knew more of art than the king. But Pliny (xxx. 95) instances the neighing of a horse, only as having decided a competition between Apelles and some other painter. Still, so far as the painter's readiness of rebuke is concerned, these stories are confirmed by other incidents, as when he told an artist, who boasted of his speed in work, that the wonder was why he could not produce more of such stuff in the same time; or, when having once accepted correction from a shoemaker about a wrongly painted boot in one of his pictures, he declined further criticism from him, with the observation which has since become a proverb, *Ne supra crepidam sutor judicaret* (Pliny, xxxv. 84). Of an opposite kind were his relations with Protogenes, the Rhodian painter, whose abilities he readily recognised, and whom he brought into notice by spreading a report that he intended to purchase his friend's pictures, and sell them as his own. Finding Protogenes not at home on one of his visits, Apelles, instead of leaving his name, drew with a brush an exceedingly fine line on a prepared tablet. Protogenes knowing the hand, and accepting the challenge, drew within the line a still finer one in another colour. But Apelles returning, divided the line a third time, and was confessed the victor. Though Ephesus continued to be his home, Apelles worked also elsewhere, as in Smyrna, Samos, and Rhodes, but principally in Cos, where he received the rights of a burgess, and where probably he died. For an account of his works and style, see ARCHÆOLOGY (CLASSICAL). (A. S. M.)

APENNINES, an extensive range of mountains traversing the entire extent of the Italian peninsula, and forming, as it were, the backbone of that country. The name Apennines is probably of Celtic origin, and derived from *pen*, properly signifying a head, or mountain height. By the Greek and Latin writers the name is generally used in the singular, as *Apenninus Mons*, ὁ Ἀπέννινος, τὸ Ἀπέννινον ὄρος. The name may have been originally applied only to a particular mountain, and afterwards extended to include the whole chain.

The Apennines may be considered as a southern branch of the great Alpine system of Europe. Both the mountain systems have a general resemblance as regards the age and lithological character of the rocks and strata which compose them. Geographers have differed as to the point where the Apennines are to be distinguished from the Alps. Some have placed it at the pass of Bocchetta; others at the Col di Tenda; and others at the low pass which runs from Savona to Cairo. Strabo, who gives a very accurate account of the general features and direction of this chain, considers it as beginning in the vicinity of Genoa. From Col di Tenda the Apennines run in a semicircle round the Gulf of Genoa, in a general direction from west to east; they afterwards turn to the south, and traverse the whole of the Italian peninsula to the Strait of Messina. The entire length of the chain is about 600 miles measured in a direct line, and about 800 miles if measured along the windings. The chain lies between 38° and 44° 30′ N. lat., and 7° 40′ and 18° 20′ E. long. The mountains are divided into the Northern, Central, and Southern Apennines.

The *Northern Apennines* include what are usually designated the Ligurian and Tuscan Apennines. The Ligurian Apennines extend from the Maritime Alps past Monte Gisa to the borders of Tuscany. The principal passes here, between Piedmont and the duchy of Genoa, are through the valleys of the Tanaro, the Bormida, and the Lemma. The pass of Pontremo leads up the Magra Valley from Spezzia to Parma. The Tuscan Apennines extend from Monte Pellegrino to Monte Cornaro, in 12° 3′ E. The Alpi Appuani form an outlying mass of mountains between the valley of the Magra and the Secchio. The chief passes are those of Bratello, Fiumalbo, Monte Carelli or Pietra-Mala, and that proceeding from the valley of the Sieve, over Borgo di San Lorenzo, through the valley of the Lamone, and on towards Faenza.

The *Central* or *Roman Apennines* comprehend that part of the chain between Monte Cornaro, in which the Tiber rises, and Monte Velino, north of Lake Fucino. Its general direction is from N.N.W. to S.S.E. or nearly parallel to the Tiber. The descent towards the Adriatic is continuous and direct, but towards the Mediterranean it forms two distinct inclined planes. The principal passes from the north are at the village of Scheggia, where the Cantiano rises; at Serravalle, south-east of Monte Pennino, at the head of the valley of the Chienti; at Castellucio, between Norcia and Arquata; and the chief pass of all between Rieti and the valley of the Pescara.

The *Southern Apennines* include the remaining portion of this chain. From Monte Velino they proceed in a south-easterly direction to the valley of the Ofanto, which cuts through the range. South of that limit, one short branch extends eastward towards Altamura, another runs westward to the neighbourhood of Salerno, while the main chain is prolonged nearly due south to the heights of Aspromonte overlooking the Strait of Messina. In the upper part of the Southern Apennines a number of sharp pyramidical points raise themselves above the mountain chain. Among these are Monte Forcone at the source of the Sangro, Monte Sant' Angelo, above the sources of the Volturno and Trigno, and Monte Calvello north-east of Salerno. The principal pass over this part of the Apennines is that of Sulmona, near the sources of the Volturno, so called from the town of Sulmona, where the roads from Rome, Pescara, and Aquila unite. The passes above Castel Franco and Ariano are the highest points of the roads over the ridge, from Benevento to Troja, and from Avellino to Foggia.

The geology and palæontology of the Apennines have been fully investigated by Savi, Meneghini, Pareto, Lavini, Orsini, Bianconi, Mortillet, and others. As a general rule, the same formations occur here as in the Alps, and the system usually consists of a central ridge having secondary and lower ridges running parallel with the main range, the intervening country being formed of but slightly disturbed newer Tertiary deposits. Thus, in that portion of the Apennines which borders on and extends into Tuscany and Bologna, the system consists of two parts. The one which is most distant from the Mediterranean forms the Apennines proper; here the Eocene beds prevail, and are covered, especially on the north flank, by Miocene and Pliocene beds; the axes of elevation are numerous and parallel to each other, following strikes which run from W.N.W. to E.S.E., and from N.W. to S.E. The other part is nearer the Mediterranean, and is remarkable for its richness in metalliferous ores, the rocks prevalent in it belong to the Palæozoic and Oolitic periods, and have a N.N.W. to S.S.E. strike. Between Spezzia and Civita Vecchia it is represented by numerous outliers of verrucano (probably of Carboniferous age), and trias surrounded by Oolitic rocks. The district of Carrara abounds in marbles belonging to the Liassic and Oolitic periods. Nearly all the mountains between Carrara and Monte Sagra have beds of marble, which sometimes acquire considerable thickness, as for instance in the vertical escarpments of Monte Corchio. The mountains between the meridians of Genoa and Parma form but one chain, composed of parallel ridges striking W.N.W. to E.N.E. The strata consist of Eocene formations flanked by Miocene and Pliocene beds, pierced by numerous ophiolitic masses. Towards Genoa the mountains conform to the S.S.W. and N.N.E. directions of the Western Alps; the rocks are of Eocene age, but are much metamorphosed by the serpentines of Pegli, Voltri, and Varagine. In the Central Apennines there is a large development of secondary beds from the trias to the upper chalk, and of the Tertiary formation, which is represented by strata of the Eocene, Miocene, Pliocene, and Post-Pliocene periods. The main axis of the chain is chiefly formed of the Secondary rocks, while the minor ranges are formed of Tertiary beds. The mountains, as a whole, rise from N. to S., culminating in Monte Corno, 9593 feet high, beyond which their height again decreases. Mount Amaro is 8960 feet, and Mount Velino 7910 feet high. The oldest rock seen in this part is a dolomite; it is unfossiliferous, and acquires its greatest massiveness in the mountains of Cesi, Spoleto, and Ventosa. Above it follows a limestone, which is in places many hundred yards thick. Fossils are rare in it as a whole, though locally abundant in a few places. The strata which next succeed are ferruginous limestones and marls, abounding in Middle Liassic fossils; then red limestones, yielding ammonites and other shells of the Upper Lias; then a vast series of limestones, marls, and siliceous beds, which compose a large part of the flanks and summits of the Apennines, and which represent the Oolitic period. The hippuritic chalk is largely developed, and in places it forms the mass of the Apennines, as in the Rossa Chain, and the lofty ranges of the Abruzzi. Fossils are abundant in this limestone. The Upper Cretaceous beds are represented by massive limestones with comparatively few fossils. Above these follow a nummulitic limestone, marly schists, arenaceous macigno, &c. The Miocene beds are varied in their lithological nature and rich in fossils. The more recent strata seldom occur at any great height above the sea.

France*, 2d series, xii. 1202–1232; Pareto, in *Bull. Soc. Geol.*, xix. 239–320, Bianconi, *Ibid.*, xxiv. 482; and Ponzi, *Giornale Arcadico*, new series, vol. xxiii.)

APENRADE, a town of Prussia, in Schleswig, beautifully situated on the Apenrade fiord, an arm of the Little Belt, 38 miles N. of Schleswig. It is connected by a branch line with the main railway of Schleswig, and possesses a tolerably good harbour, by means of which it carries on a considerable transit trade, while there are also several manufactures, as well as some shipbuilding and sea-fishing. Population, 5932.

APHASIA (from α and φάσις; synonyms, *Aphemia, Alalia, Aphrasia, Aphthongia, Aphthenxia*), a term applied to indicate a condition in which the function of expressing ideas by articulate sounds is arrested, perverted, or destroyed, in consequence of lesion of the brain. Loss or perversion of the power of expressing ideas by written signs is often associated with this condition. The term Aphasia is generally held to comprise two great varieties: (1), Amnesic Aphasia, in which the memory of words is lost or perverted; and (2), Ataxic Aphasia, in which the function of articulation is lost or perverted. Although this broad distinction is very properly made, it very rarely happens that a case occurs in which the two conditions are not to a greater or less extent coexistent.

Amnesic (α, μνῆσις) aphasia is symptomatised very variously. The earliest and most common indication consists in—(α.) The loss of the memory of substantives and names, other parts of speech being properly applied; in such cases a periphrasis is employed to express the term. (β.) The memory of a language with which the patient had been thoroughly conversant may become lost. (γ.) Terms are persistently misapplied; for instance, in recorded cases "pamphlet" has been used for "camphor," "hogshead" for "sugar," "horse" for "man," &c., &c. This symptom has been named Heterophasia (ἕτερος, φάσις). In *ataxic* (α, τάξις) aphasia—(α.) the function of articulation is completely lost, the patient being only able to indicate by signs that he is conscious of the idea conveyable by the term; thus an ataxic aphasic, who had been an engine-driver, when asked what had been his trade, could only express himself by imitating the sound made by an engine when starting, "Hish, hish, hish." In many instances even this power of imitation is in complete abeyance—assent to the fitness of a spoken word to indicate the object exhibited being given by a nod or other gesture. (β.) The function of articulation is modified; thus a word may be only half articulated; for instance "watch" can only be pronounced as "wa," no prompting, or effort on his own part, enabling the patient to complete the word. (γ.) Only automatic phrases can be articulated, oaths, "yes," "no," "aye," &c. (δ.) The patient makes use of a set phrase, which may consist of actual words, but more frequently of confused sounds, such as "tan tan," "ta ta," "didoes doe the doe," &c.; but such phrases do not appear to satisfy him as expressive of ideas, although only one is persistently employed. In almost all cases of ataxic aphasia there is a well-marked desire and effort to enunciate words, the muscles of articulation often working strongly but convulsively. The great diagnostic point between amnesic and ataxic aphasia is, that in the former the patient can always articulate the forgotten word when it is suggested to him; in the latter, no prompting or assistance can enable him to enunciate the proper sound. Closely associated with both forms of aphasia is the loss of the power of expressing ideas by written signs. To this condition the term agraphia (α, γράφειν) has been applied. Most frequently this power is completely lost, the effort of putting pen to paper being only followed by a confused scribbling; occasionally a strong effort is made to write; for instance, the patient makes a feeble endeavour to make his signature, which results in the production of a badly-formed initial letter, the subsequent ones being either quite unformed, or represented by a confusion of wrong signs. In the most slightly-marked cases of agraphia, *i.e.*, those in which the patient is able to produce actual graphic signs, the general character of the handwriting is completely changed from that which had existed during health.

Aphasia, whether amnesic or ataxic, may, but seldom does exist disassociated from absolute insanity.

Great interest has centred around the question of the pathology of aphasia, as many observations have been adduced which appear to connect with this condition lesion of a specific portion of the brain, and from this it has been sought to deduce the absolute localisation of the function of speech in the hemispherical ganglia. The large proportion of cases of ataxic aphasia occur in association with right-sided hemiplegia, although others are on record in which it has appeared in connection with left-sided hemiplegia in left handed persons. Bouillard, Andral, and Dax placed on record a series of cases which bore upon the association of disease of the frontal lobes of the brain, with loss of the faculty of articulate speech. In 1861 Broca of Paris enunciated the theory, founded on the clinical and pathological observation of two carefully reported cases, that the portion of the cerebrum which is necessarily diseased in aphasia is the *posterior third of the third or inferior left frontal convolution*. A large number of cases have since been published which appear to support this theory; but an almost equally large number have been recorded in which disease of this portion of the above-named convolution has been found without material impairment of speech, in which it has been found intact in cases of aphasia, or in which disease of other convolutions has been accompanied by similar symptoms. Broca's positive localisation of the function of speech has been disproved by several well-authenticated cases; it is, nevertheless, held by many prominent pathologists, that, although his deduction is not absolutely correct, it is in the main true, as lesion of the portion of the brain indicated by Broca may affect neighbouring convolutions of the frontal lobes, in which their observations lead them to believe the function of speech is localised, although its seat cannot be exactly indicated. Another section of pathologists hold that the nutrition of the whole encephalon is effected by lesion of this particular convolution, the locality of which, by its anatomical relations to the middle cerebral artery, is peculiarly liable to embolus and apoplexy, and that as a consequence, the faculty of speech is affected in common with other cerebral functions; and they further argue, that, as destruction of other portions of the cerebrum has been known to be accompanied by similar symptoms affecting speech (the left inferior frontal convolution being intact), it is in no wise proved that localisation of function can be fairly deduced from the occasional association of lesion of this convolution with aphasia.

(See Dr Bateman, *On Aphasia*; papers by Drs Tuke and J. Fraser in the *Journal of Mental Science*, 1870; Dr Ferrier "On the Localisation of Brain Function," *West Riding Reports;* and for bibliography, *Dictionnaire Encyclopédique des Sciences Médicales*.) (J. B. T.)

APHORISM (ἀφορισμός, from ἀφορίζω, to define) is a terse and definite statement of a principle or important doctrine in science or philosophy. The word has been used as the title of some well-known works—as the *Aphorisms of Hippocrates*, the *Aphorisms of the School of Salerno*, and the *Aphorisms of Boerhaave*, which represent respectively the medical doctrines of the 5th century B.C., and the 12th and 17th centuries of the Christian era. One of the best specimens of a philosophical treatise wholly written in aphorisms is the *Novum Organum* of Lord Bacon.

APHRODITE [VENUS]. From the accepted meaning of the name Aphrodite, "born in the foam of the sea," (ἀφρός), together with Hesiod's (*Theog.*, 187–206) account of her appearing first in the waters round Cythera, and finally landing on Cyprus; and from the further explanation of her principal title *Urania*, to the effect that she derived her being from the maimed Uranos, this goddess might appear to have been of pure Greek origin, as indeed would also be gathered from the fact of Homer placing her among the Olympians, and calling her a daughter of Zeus and Dione. But her connection with Cyprus, which even Homer admits, calling her *Kypris* (*Iliad*, v. 330, 422, 760), and in the *Odyssey* (viii. 362), speaking of her visit to Cyprus, where were a temple and an altar for her, has provoked an inquiry as to how far her worship may have been based on that of Astarte, the patron goddess of the Phœnician settlers in that island, the more so since the worship of Aphrodite Urania flourished mainly in the track of the Phœnician factories in the islands and in Greece proper. The obvious facts are—first, that Aphrodite was not associated with any of the legendary families of the mainland of Greece, her mortal favourites—Adonis, Pygmalion, Anchises, Æneas, Paris—being all non-Hellenic, and more or less Asiatic in origin; secondly, that her worship in Cyprus, as Herodotus was told (i. 105), had been transplanted from Ascalon, where was the oldest temple of a goddess whom the Greeks translated into Aphrodite Urania, and identified with the Alitta of the Arabians, the Mylitta of the Assyrians, and the Astarte of the Phœnicians; thirdly, that this Astarte or Mylitta was a goddess of the heavens (Urania), or better, of the heavenly bodies, and, though the details are unknown, doubtless personified the harmony of their movements while controlling their supposed influence on human affairs, not least their influence on the sea, in which respect her worship would commend itself to a seafaring and trading people like the Phœnicians. As the universal goddess of love, her province embraced every phase of nature. While this, which was the basis of the character of Astarte, was the basis also of the character of Aphrodite; and while, through commercial ascendency, the alphabet of the Phœnicians, and their system of numbers, weights, and measures were adopted by the Greeks, there is nothing in the way of assuming that the idea of their goddess Aphrodite was borrowed under similar circumstances. If the 15th century B.C. be correctly assigned as the period of the Phœnician settlements in Greece, there would be interval enough before the time of Homer to admit of the new goddess becoming Hellenised and obtaining a place in Olympus; and this would be brought about with the greater facility if, as is supposed, the Oriental goddess really supplanted a cruder form of a goddess of love previously existing in the Greek system. How widely the scope of love was interpreted in the last days of Greece, may be seen, on the one hand, from the manner in which the unseemly account of the birth of Aphrodite in Hesiod was elevated into a scene at which all the higher deities were present, as rendered by Phidias on the base of the statue of Zeus at Olympia; and, on the other hand, from the fact that the philosophers, particularly the earlier thinkers in natural philosophy, conceived heaven, earth, and sea as bound into an harmonious whole by the power of love. A very different interpretation was put upon it in later times when sensual indulgence was the master feeling, and Aphrodite became the patroness of hetæræ. For these two different characters she bore the titles of *Urania* and *Pandemus*. Under the former title she was not only a goddess of the heavens, in respect of the fertility which they produce on earth, but was also a goddess of victory, either herself armed or occupied with the arms of Ares (Mars). Her power extended to the sea, but only to soothe it, and hence she was worshipped in seaports with the epithet of εὔπλοια. Where her influence, however, was mostly felt was in the gardens among the flowers in springtime. It was then that her principal festivals occurred, and in such places and at such a time the full charm of her character as goddess of love was appreciated. The Graces (*Charites*) and the Seasons (*Horæ*) worked her garments with flowers, from which a scent came as in nature. The sweetness of her smile, her persuasive voice, and her entire beauty were then irresistible. From being the goddess of beauty and love throughout nature, she became goddess of love in the hearts of gods and men; either inspiring a passion for herself, as in the case of Pygmalion and Anchises, or herself inflamed with love, as for Adonis and Cinyras, the reputed founder of her worship in Cyprus; or again inspiring a passion between two other persons, as between Paris and Helena, and between Phaon and the women of Lesbos. When the subjects were women, her power was frequently carried to a desperate issue, as in the cases of Medea, Pasiphae, Phædra, and many others. But she gave also the pleasures of love, and while this led to the degradation of her character finally, it was differently viewed in earlier times, in which she was in this matter simply the goddess of domestic life and of the relations between families, being in some places associated with Eileithyia, the goddess of childbirth, or elsewhere regarded, like Artemis, as a guardian of children and young maidens. It seems, indeed, as if it had been for the protection of family love that she was made to assume after Solon's time the protection of the institutions for hetæræ. Among the other deities her power and also—after the rivalry of Hera (Juno) and Athene (Minerva) had been set aside by the judgment of Paris—her surpassing beauty were acknowledged. Eros (Cupid), the male personification of love, who at one time is called her son, at another is present at her birth, is the chief of her companions, the others being Himeros, Pothos, Anteros, Peitho, the Graces, and the Seasons. She was the wife of Hephæstos (Vulcan), and if in that capacity she was unfaithful with Ares, as in the ludicrous incident when the two were caught in the cunning net made by her husband, there yet appears some ground for the invention of this myth, in the fact of her being associated in worship with Ares at Thebes. Her connection with Ares may have originated in the character of *Areia*, which she derived from the Oriental goddess, her prototype. As an armed goddess she appeared at Cythera and in other of the earliest seats of her worship. It was only as *Charis*, the personification of grace and refined skill, that she could have been the wife of Hephæstos, and this is the name which in that capacity she bears in the *Iliad*. In the Trojan war she was opposed to the Greeks, and protected Æneas, Hector, and Paris. The chief seats of her worship were Cyprus, Cythera, Cnidus, Corinth, Thebes, Sicily, and Athens. Her usual symbols were the tortoise, dove, swan, hare, dolphin, and goat. In Paphos, where was the oldest form of her religion, she was worshipped under the image of a ball or pyramid surrounded by burning torches. In the best days of art every charm of beauty was exhausted for her statues, culminating in the Aphrodite at Cnidus by Praxiteles. Of existing statues, the Venus of Milo and the Venus of Capua are the best examples. With regard to the native Roman goddess Venus, as distinguished from the Venus who through contact with the Greeks was afterwards identified with Aphrodite, it is known that her worship did not exist in the time of the kings, and that it was introduced into Rome from Lavinium, Ardea, and Gabii, where she was connected with Æneas and his advent into Italy. But for the rest, whether she was the goddess called Venilia, or a native goddess of gardens, is uncertain. Doubtless her functions were in important instances exchangeable with those of Aphrodite; and this being so, it was an obvious gain to incorporate with their own goddess another whose relations with Mars and Anchises, the founders of the Roman race, were express and distinct.

Aphrodite and Eros, from carnelian intaglio in Brit. Mus. (enlarged).

In her sway over the productivity of the fields Venus was associated with Priapus; in the spring time with its flowers she was sacrificed to by young maidens; in war she was Victrix; in peace, Concordia and Conciliatrix; on the sea she was Marina; as Libentina (Lubentina) she was goddess of desires; as Libitina, goddess of death; and as Genetrix, the founder of families, especially of the Julian family. The derivation of her name given by Cicero (*De Nat. Deor.*, ii. 27, iii. 24) is *Venus quod ad omnes veniat.* (A. S. M.)

APICIUS. There were three Romans of this name, all celebrated as epicures. The second, M. Gabius Apicius, who lived under Tiberius, is the most famous. He invented various cakes and sauces which bore his name, and rival schools of cookery claimed their descent from him. A treatise, *De Re Culinaria, sive de Obsoniis*, &c., bearing the assumed name of Cælius Apicius, was compiled at a later period.

APION, a Greek grammarian and commentator upon Homer, son of Posidonius, was born at Oasis in Libya, but called himself a native of Alexandria, where he studied. He taught rhetoric at Rome about 30 A.D. With extensive knowledge and great oratorical power he combined an unbounded vanity, as the epithet *cymbalum mundi* applied to him by Tiberius seems to imply. Mere fragments of his works remain; the stories of Androclus and the lion and of the dolphin at Puteoli—the largest of these fragments—are preserved in Gellius. Apion headed the embassy sent by the Alexandrians to Caligula complaining against the Jews, 38 A.D. Josephus refutes his misrepresentations of the Jews in the second of his two books "Against Apion."

APIS, a sacred bull worshipped at Memphis from the earliest period, having probably been introduced into the religious system as early as the 2d dynasty by the king Kaiechos, who instituted the worship of Apis and the bull Mnevis. His name in hieroglyphs was *Hapi*, and meant "the hidden," as he had to be discovered amidst the cattle, which was done by certain diacritical marks. According to the hieroglyphic inscriptions which accompany his form, he was the second birth or living incarnation of the god Ptah, the Egyptian Hephæstos or Vulcan. Apis is first mentioned and appears in the monuments of the 4th dynasty. The two bulls Apis and Mnevis are considered to have respectively represented the moon and sun, and seem both to have been buried at Memphis. He was supposed to have been born of a virgin cow, rendered pregnant by a moonbeam or a flash of lightning. The mother of Apis, according to Strabo, had a part of the temple of the Apis reserved for her use; and the hieroglyphic inscriptions record a prophet or priest attached to her service. On the monuments she shares the honours of the bull, and is represented under the attributes of Athor as a goddess with a cow's head. This cow had her especial name, these animals having each a separate appellation. According to the Greek writers Apis was the image of Osiris, and worshipped because Osiris was supposed to have passed into a bull, and to have been soon after manifested by a succession of these animals. The hieroglyphic inscriptions identify the Apis with Osiris, adorned with horns or the head of a bull, and unite the two names as Hapi-Osor, or Apis Osiris. According to this view the Apis was the incarnation of Osiris manifested in the shape of a bull. But besides this title, the monuments style Apis the son of Ptah, who was supposed to be his father by the sacred cow, or the second life of Ptah. Other monuments, indeed, declare him to have had no father, and to have been Onnophris or Osiris, but this conflict of ideas must have arisen from his material and spiritual nature, uniting the soul of Osiris or Ptah mystically with the sacred animal. Besides the mother of the Apis, a cow was annually exhibited to him decorated with the same insignia—that is, a disk between the horns and a housing on the back, to judge from the insignia found on the bronze figures of the Apis—and then slaughtered the same day, for no issue of the divine animal was permitted to exist. According to other authorities several cows were kept in the Apeum. On the announcement of the birth of an Apis, the sacred scribes and priests proceeded to verify the characters of the calf. The marks of the Apis were a black coloured hide, with a white triangular spot on the forehead, the hair arranged in the shape of an eagle on the back, and a knot under the tongue in shape of a scarabæus, the sacred insect and emblem of Ptah, a white spot resembling a lunar crescent at his right side. These marks have been supposed to be for the most part certain arrangements of the hairs of the hide as seen in some animals. A house was built to the calf Apis facing the east, in which for four months he was nourished with milk. When he had grown up he was conducted, at the time of the new moon, to a ship by the sacred scribes and prophets, and conducted to the Apeum at Memphis, where there were courts, places for him to walk in, and a drinking fountain. According to Diodorus, he was first led to Nilopolis, and kept there 40 days, then shipped in a boat with a gilded cabin to Memphis, and he was there allowed to be seen for 40 days only by women, who exposed themselves to him. Like all the sacred animals his actions were oracular, and he had two chambers, his passage into one of which was deemed fortunate, and into the other unlucky. Thus the licking the garments of a visitor was supposed to prognosticate a tranquil but short life, and his refusal of the food offered to him by the hand of Germanicus, the approaching death of that hero. The actions of the children who played around his shrine or accompanied his processions were also considered oracular. The day of his birth was kept as an annual festival. His life was not allowed to exceed 25 years, and should it have attained that maximum reckoned from the date of his enthronisation, the Apis was killed and thrown into a well, in which the priests asserted he had precipitated himself. This well was known to no one, and no one was allowed to reveal the place of burial. If the Apis died before the 25 years he received a splendid burial at Memphis in the Serapeum, for after death he was called the Osor-hapi, or Serapis. This funeral was expensive; his body was placed in a barge, and accompanied by a procession of a Bacchanalian character, passing through the brazen doors of Memphis. As universal joy prevailed at his discovery, so his death threw all Egypt into a general mourning, and every one shaved off his beard. This mourning continued till the discovery of another Apis. His birthday was celebrated by an annual feast, the *natales Apidis*, of seven days' duration, during which it was supposed the crocodiles were innocuous, and a silver cup was thrown on the occasion into a certain part of the Nile, which was considered a flux of Apis. This festival coincided with the rise of the Nile. On the mummy coffins an Apis is often seen on the foot-board of those of the 7th and 6th centuries B.C., bearing on the back the mummy of the deceased to the sepulchre. The discovery by M. Mariette of the Serapeum at Memphis described by Strabo has thrown great light on the worship and history of the Apis, the mode of burial, and the sequence of the bulls. (See SERAPEUM.) The oldest Apis mentioned was one of the reign of Amenophis III., and he was followed in the 18th dynasty by bulls which had died in the reigns of Tutankhamen and Horus. There was a succession under the 19th dynasty, commencing with Seti or Sethos I., besides three which died in the 16th, 26th, and 30th years of Rameses II., and three others, the dates of whose deaths are unknown. Under the 20th dynasty there was an Apis which died in the

26th year of Rameses III., one in the reign of Rameses IX., others of the date of Rameses XI. and XIV., and four others whose dates are not determined, besides three more which died under the 21st dynasty. Of bulls deceased in the 22d dynasty, there is one of the 23d year of Osorkon II., another of the 14th year of Takellothis I., and a third of the 28th year of Sheshank or Shishak III. It is not till the reign of this monarch that the dates connected with the Apis become of chronological importance. On the sepulchral tablet of the Apis which was born in the reign of Shishak III., is found the formula of the date of the birth and inauguration of the bull. It was born on the 20th of the month Payni, in the 28th year of the king's reign, and enthroned on the 1st of Paophi of the same year, having died in the 2d year of the king Pamai, and been buried on the 1st of the month Mechir of the same year. It had attained the age of 26 years. Three other bulls died in the 4th, 11th, and 37th years of Shishak IV. Important statements like these show the intervals of time which elapsed between the regnal years of different kings, and check the chronology of the 22d and subsequent dynasties, but owing to unfortunate lacunæ the chronology of Egypt is conjectural, and not positive till the reign of Tirhakah. The dates of the other Apis are, one which died on the 5th of the month Thoth, in the 6th year of Bekenreuf, or Bocchoris, another of the 2d year of Shabak or Sabaco, and that buried on the 23d Pharmouthi of the 24th year of Tirhakah, 730 B.C. The dates of the other bulls prior to the conquest of Egypt by Alexander the Great, 332 B.C. are—one born in the 26th year of Tirhakah, enthroned on the 9th Pharmouthi, the same year deceased, in the 20th year of Psammetichus I., and buried on the 25th Paophi, of the 23d year of Psammetichus; another deceased in the 52d year of the same king; a third born in the 53d year of Psammetichus I., enthroned on the 12th of Athor of the 54th year, deceased on the 6th of Paophi, and buried on the 10th Choiak of the 16th year of Necho, having lived 16 years 7 months and 17 days; another born on 7th Paophi of the 16th year of Necho, enthroned 9th Epiphi of the 1st year of Psammetichus I., died on the 12th Pharmouthi of the 12th year of Apries, and buried the 21st Payni of the same year, aged 17 years 6 months and 5 days; another born in the 5th year of Amasis, inaugurated on the 18th Payni of the same year, died on the 6th Phamenoth, was buried on the 15th Pashons of the 23d year of the same king, aged 18 years and 6 months. The Apis which died after this, and of which a sarcophagus was found dated in the 4th year of Cambyses, is the one supposed to have been killed by Cambyses on his return from Æthiopia. Another born in the month Pharmouthi of the 5th year of Cambyses, died in the 4th year of Darius, and was buried on the 2d Pashons of the 5th year of Darius, and had lived upwards of 7 years. It is the Apis of Darius, alluded to by Polyænus, for the successor of which Darius offered 100 talents as a reward to the fortunate discoverer. Another Persian king Ochus is said to have killed and eaten an Apis, 338 B.C. The death of an Apis soon after the death of Alexander the Great, 323 B.C., is also recorded. The sepulchral tablets in the demotic characters, according to M. Brugsch, record the birth of an Apis in the month of Phamenoth, in the 20th year of Ptolemy Euergetes I., 231 B.C., which died in the 51st year, 179 B.C.; and another older, probably of Ptolemy Philadelphus II., 253 B.C.; another of the 14th year of Ptolemy Epiphanes IV., 211 B.C.; another in the 20th year of Ptolemy IV., 185 B.C.; another in the 17th year of Ptolemy Philometor VII., 164 B.C.; and another born in the 53d year (118–117 B.C.) of Ptolemy Euergetes II., died 15 years old, 103 B.C., in the reign of Ptolemy XI. In the Roman times the discovery of an Apis in the reign of Hadrian, 121 A.D., caused a tumult at Alexandria; and the last known Apis is that brought to the Emperor Julian II., 362–363 A.D., after which the Apis disappears from Egypt altogether. The Apis was embalmed at great cost, but the operation consisted in preparing with bitumen the skull and a few of the principal bones of the bull made up into an appropriate shape. The second genius of the Karneter, or Egyptian Hades, was also called Hapi or Apis, but he was quite distinct from the bull god and the son of Osiris. His type was that of a human mummy with the head of a Cynocephalus ape. Bronze native figures of the Apis are not uncommon, and those of stone are occasionally found, but porcelain ones are extremely rare.

APOCALYPSE, a designation under which the last book of the New Testament is frequently referred to. It is the title the book has in the Greek, Ἀποκάλυψις, which in the English version is rendered "Revelation." See REVELATION OF ST JOHN. The name is applied generally to predictions relating to the growth and triumphs of the Messiah's kingdom, especially as revealed in visions or expressed by means of symbols. The more important extra-biblical writings of this kind are noticed in the article which immediately follows.

APOCALYPTIC LITERATURE. This branch of later Jewish literature took its rise after the older prophecy had ceased, when Israel suffered sorely from Syrian and Roman oppression. Its object was to encourage and comfort the people by holding forth the speedy restoration of the Davidic kingdom of Messiah. Attaching itself to the national hope, it proclaimed the impending of a glorious future, in which Israel, freed from her enemies, should enjoy a peaceful and prosperous life under her long wished for Deliverer. The old prophets became the vehicle of these utterances. Revelations sketching the history of Israel and of heathenism are put into their mouths. The prophecies take the form of symbolical images and marvellous visions. As the old remained unfulfilled in the progress of events, and doubts arose about their truthfulness, it was necessary to give them a new turn and a more correct interpretation. Working in this fashion upon the basis of well-known writings, imitating their style, and artificially reproducing their substance, the authors naturally adopted the anonymous. The difficulty was increased by their having to paint as future, events actually near, and to fit the manifestation of a personal Messiah into the history of the times. Hence apocalyptists employed obscure symbols and mysterious pictures, veiling the meaning that it might not be readily seen. The artificial imitative character of their productions caused certain peculiarities; and the main object was attained by fastening the spirit of their contemporaries on the immediate fulfilment of their highest aspirations. From the intentionally dark imagery enfolding the ideas, it is difficult to discover the exact times of their appearance and the historical interpretation.

The earliest of such apocalypses is the canonical book of Daniel, in which an old seer in the Chaldean captivity is employed to portray the oppressions of the Jews under Antiochus Epiphanes. This was the model for all later ones. The literature in question was not confined to the Jews. Christians not only used the productions in which the Messiah was described after the Jewish fashion, but composed similar ones themselves,—Jewish Christians in particular. Here the Apocalypse of John is the noblest example, and deserves the honour of naming the entire range of literature.

The most obvious division of apocalyptic works is that founded upon authorship, Jewish or Christian. This, however, cannot be carried out with exactness because of later interpolations, proceeding from Christians who used the Jewish prophecies with the objects of making them more suitable. But it is not easy to trace the extent of subsequent elaborations; and we have only to rely on probable conjecture.

I. Jewish Apocalyptic.

1. *Enoch.*—Under the name of this antediluvian patriarch a book exists which is quoted in the epistle of Jude. After it had disappeared, except the fragments preserved by ecclesiastical writers, it was found in Ethiopia among the Abyssinians, and published by Laurence in 1821; subsequently by Dillmann in 1851, to which the latter scholar added a German translation in 1853. The book has been divided into five parts, exclusive of an introduction and a conclusion. The first contains an account of the fall of the angels, and their intercourse with the daughters of men producing a race of giants, with the consequences of such apostacy; followed by a description of Enoch's travels through heaven and earth under the guidance of holy angels, who explain to him the mysteries of the visible and invisible world (chapters vi.–xxxvi.) The "second vision of wisdom" is occupied with a description of the mysteries belonging to the heavenly kingdom, the angel-world, the Messiah, the growth and completion of His kingdom, the blessedness of the elect, and the condemnation of the unbelieving (xxxvii.–lxxi.) The third part is astronomical and physical, including an account of the movements of the stars, the sun, and the moon; of the four winds, and various earthly objects (lxxii.–lxxxii.) The fourth part describes two dream visions shadowing forth the history of man, from his origin to the completion of the Messianic kingdom (lxxxiii.–xci.) The fifth contains a series of admonitory discourses addressed by Enoch to his own family in the first place, and then to all inhabitants of the earth (xcii.–cv.) Several appendices are subjoined containing a narrative of the wonders which happened at Noah's birth, and a writing of Enoch's about the future retribution of the just and unjust (cvi.–cviii.)

The work contains much curious matter about the secrets and powers both of the visible and invisible world. Besides its historical views which relate mainly to the past, present, and future of the Jewish people, as also to heathen kings and potentates, much of the legendary and hagadic is interspersed. Daniel's seventy weeks, reaching down to the Messianic age, are changed into seventy periods of heathen rulers. The writer has withal a religious spirit. He is a strict moralist, warning and threatening. His imagination is vivid, but incapable of sublimity. The sweep of his prophetic vision is extensive. He has poetic force and vigour. The work is an interesting product of pre-Christian Judaism, multifarious, artificial, rabbinising.

The document consists not only of the prophecy of Enoch, but of extracts from a Noah-prophecy interspersed. The latter are found in places often unsuitable, consisting of chapters liv. 7–lv. 2, lx., lxv.–lxix. 25; perhaps also of xx. and lxx. In cvi., cvii. the same hand may be partly traced. Setting aside these insertions, the book of Enoch itself seems to be composed of three documents, the oldest of which is chapters xxxvii.–lxxi. The other two are not easily collected, but the chapters xci. 3–cv. have the clearest claim to belong to the second, and xxxiii.–xxxvi., lxxxv.–xc. to the third. The rest is all uncertain. The first was written about 144 B.C. as Ewald[1] acutely remarks; the other two fall some years later, *i.e.*, within the reign of John Hyrcanus (136–106 B.C.) The Noah-document is posterior, belonging perhaps to the first century; and all were subsequently put together, forming the present heterogeneous composition. Hilgenfeld contends that chapters xxxvii.–lxxi. proceed from a Christian Gnostic,[2] but his arguments are insufficient. Still more improbable is the hypothesis of Volkmar, that the entire Apocalypse was written 132 A.D.[3] We believe, however, in opposition to Dillmann, that they have been interpolated by a Jewish Christian, since the christology is higher than what Judaism produced; while the eschatology and angelology are developed in a manner which savours of Christianity. Thus, in the 51st and 62d chapters the Messiah is described as sitting on the throne of His glory and taking part in the judgment, while He is also called the Son of woman, the Son of man. To make Messiah the judge of mankind, either as the delegate of the Father, or together with Him, is not a Jewish, but a Christian idea. This differs from the representation in the 90th chapter, where he is symbolised by a white bull with great horns, whom all the beasts of the field and all the birds of heaven feared and entreated at all times. All races are to be changed into white bulls; the first among them became a great animal; and the Lord of the sheep rejoiced over them and all the bulls. Here Messiah is simply the chief of God's people, elevated above the rest, but still of the same nature with them, having no share in the judgment, or in founding the new church of God. He comes into the description by way of appendix, as it were, as though the author could not well omit all notice of Him. His part is entirely subordinate. In the 105th chapter, which, with the next three, show traces of Christian influence, the Messiah is called *Son of God*,—an appellation which seems to carry the idea of His person beyond Judaism, especially in connection with that in the 62d chapter, *Son of woman*, for the two come very near the idea of an incarnation. The whole work presents no trace of Rome as a power dangerous to Israel, so that the latest parts cannot be brought down far into the 1st century. The book had a very limited circulation among the author's countrymen. They do not quote it. It proceeded from a private individual, who may have belonged to a small circle or sect such as the Essenes. But Jude cites it. It has been translated into English by Laurence; into German, but chiefly from Laurence's English, by Hoffmann; and much more correctly by Dillmann in 1853. The translation of the last mentioned scholar has superseded those of his predecessors. See also Ewald's *Abhandlung, u.s.w.*; Lücke's *Versuch einer vollständigen Einleitung in die Offenbarung des Johannes, u.s.w.*, zweyte Auflage, § 11; Koestlin, "Ueber die Entstehung des Buches Henoch" in the *Tübingen Journal of Baur and Zeller* for 1856; Hilgenfeld's *Die Jüdische Apokalyptik*; Davidson in Kitto's *Cyclopædia*, article "Enoch;" Hilgenfeld's *Zeitschrift für wiss. Theologie*, 1860, 1861, 1862.

2. Another apocalyptic production is the so-called *Fourth Book of Esdras*, or *The Prophecy of Ezra*, originally written in Greek, but known now only in versions,—Latin, Ethiopic, Syriac, Arabic, and Armenian. The whole consists of a series of visions, which Ezra, who is put unchronologically into the 30th year of the Babylonian captivity, is supposed to have had. The questions that troubled the seer arose out of the state in which the Jews were at the time. They were deeply oppressed and afflicted. The heathen had trodden them down to the ground. Why had the promises of God to His own people been unfulfilled? Was not Israel still the chosen race, though often sinning? Were they not better than the heathen? The Romans had

destroyed Jerusalem, and the Jews were scattered to the four winds; so that the writer was deeply perplexed by the establishment of a heathen power over the Jews, involving an indefinite delay of the Messianic kingdom, or an apparent hopelessness as to its inauguration. Heathenism triumphed over Judaism, rending it to pieces. What had become of the divine faithfulness? The first vision (ch. iv.–v. 20) contains an angelic answer to the questions which the seer had painfully pondered, as in the 3d chapter. After being reminded of his inability to comprehend God's ways, the signs of the end are given. The second vision (v. 21–vi. 34) is similar. The third vision (vi. 35–ix. 25) and the fourth (ix. 27–x. 59) refer to the Messianic future. The fifth, relating to an eagle coming up out of the sea (x. 60–xii. 59), describes the Roman empire, its destination and period of duration, the sixth (ch. xiii.), the setting up of Messiah's kingdom; and the seventh (ch. xiv.), an account of Ezra's re-writing the holy books. It is very difficult to discover the date of this singular book, and the question is not yet satisfactorily settled, though many critics have investigated it. One thing is pretty clear, that the destruction of Jerusalem had taken place, and that Christianity had passed its incipient stage, exercising some influence even upon Judaism. Original sin, a dying Messiah, a general resurrection, &c., point to a Christian origin; so that the passages in which these features appear, and others too, were probably interpolated. Hilgenfeld even thinks that vi. 18–vii. 45 were interpolated by a Christian at the commencement of the 3d century,[1] but his arguments are not cogent, as Langen has shown. As the data for determining the time lie chiefly in the interpretation of the eagle's wings and heads, the diversity of opinion is increased. Perhaps the 30th year after the ruin of the city (iii. 1) points to the like time after the Roman conquest of Jerusalem. The six wings of the eagle on the right side are the six Julian emperors; the six on the left, are Galba, Otho, Vitellius, Vindex, Nymphidius, Piso; and the three heads, the Flavian emperors. Either Titus's or Domitian's reign should be fixed upon; probably the latter, about 96 A.D. Hilgenfeld assigns 30 B.C.; Volkmar seems nearer the truth who gives it to 97 A.D.,[2] though some of his ingenious interpretations are far fetched. It is impossible to tell whether the author lived at Rome or in Egypt. The few internal evidences bearing on the point favour the latter.

The poetic excellence of this production is much greater than that of Enoch. It is, indeed, below the Apocalypse of Daniel; but its merit is considerable. In modern times Messrs Frere and Irving gave it a place beside Daniel and St John,—strangely combining the prophecies of the three into one, as though all were formed upon the same plan, and referred to the same events. Chapters i., ii., and xv., xvi., which need not be separated, seem to have been written by Egyptian Christians; the first two chapters about 201 A.D; the last two about 263 A.D., according to Gutschmid.[3] Like the Fourth Book of Esdras, these were also written in Greek, but exist only in a Latin translation.

The literature and numerous opinions about the date may be seen in the Prolegomena to Hilgenfeld's *Messias Judæorum;* the same work contains the different texts of it. The Latin text alone is presented by Fritzsche in his *Libri Apocryphi Veteris Testamenti Græce*, 1871; and by Volkmar in his *Handbuch der Einleitung in die Apocryphen*, 2 Abtheil., 1863. It is in the English Apocrypha, translated, no doubt, from the Vulgate. Luther left it out of his version, and De Wette followed him. The chief writers on the book in recent times are Volkmar and Hilgenfeld; but the list since Whiston and Semler is very copious.

3. *The Book of the Jubilees,* or *the Little Genesis, ἡ λεπτὴ γένεσις, parva Genesis.*—This work is apocalyptic only in part, though called the Apocalypse of Moses in the notices of it by George Syncellus and George Cedrenus. In the form of a revelation made to Moses during his stay on Mount Sinai, it professes to be intended for future races, and to contain prophetic admonitions relating to coming times. It is predominantly historical and chronological, beginning with the old histories of the creation. From the commencement of the world till the entrance into Canaan is divided into 50 jubilee years; and every event is arranged according to jubilees, years of weeks, and years. Later Jewish ideas are transferred to earlier times, especially to the patriarchal; and difficult questions connected with the ancient worship are solved. Traditional views and hagadic materials appear with Jewish ritual and exclusiveness. The author was an energetic Palestinian Jew, conversant with the history of his people, and conservative, who meant to confirm them in attachment to the faith, by narrating their past fortunes over again, and keeping them alive to their principles. Amid the multifarious contents it is not easy to trace the precise origin of the book, though it is easy to see that the author was a patriotic Jew, whose object was to keep his countrymen firm in their religion at a time when it was in great peril both from without and within. It has been assigned to an Alexandrian, an Essene, and a Samaritan source, none of which opinions can be maintained. The writer has respect to different sects and parties in Judaism, to the various tendencies existing within the old religion when he wrote; and he endeavours to mediate between them by making concessions in this direction and that,—to conciliate and blend them together, that they may be more united against anti-Jewish influences. Hence Samaritan, Essene, Sadducean, and Pharisean peculiarities are found in the work. There is little doubt that he was an orthodox Jew, who had in view the consolidation of Judaism against heathenism and Christianity—the uniting of all sects and shades of belief in the common faith of Levitical monotheism.[4] It is worthy of remark that the Hebrew text he used agrees with the Samaritan more than the Masoretic, though he himself was not a Samaritan, else he would not have mentioned Zion among the four holy places, to the exclusion of Gerizim. The date is the 1st century of our era; and before the destruction of the temple, as may be inferred from the first chapter. The writer seems to have used the book of Enoch; for he speaks in the fourth chapter of Enoch writing out the signs of heaven according to the order of their months. There are also coincident passages which go to prove the same thing. And there is evidence that the writer of the Testaments of the patriarchs employed our book; though this does not necessarily take the latter's origin into the 1st century. So, too, the Fourth Book of Esdras was used, as we infer from what is said in relation to Abraham, Esdras iii. 14, &c., and Jubilees xii. The date cannot be fixed nearer than about 50 A.D.[5] The *Little Genesis* was soon forgotten, and no trace of it appears among the Jews, except perhaps in the title of Bereshit Rabba. Yet its Midrash is of an older type than the other Midrashim; mystic and supernatural in its tendency; its angelology less developed. Jerome refers to it twice by name, and Syncellus thought highly of it. It had been rendered into Greek before the time of Jerome. Dillmann has published the Ethiopic version from two MSS., and

[5] *Ibid.*, p. 528.

translated it into German.[1] The original was Hebrew or Aramæan, as all critics allow, except Frankel, who is refuted by Langen.[2] A Greek version existed early, and was subsequently lost. From it the Ethiopic was made. In 1861, Ceriani published from a palimpsest in the Ambrosian library at Milan, considerable fragments of an old Latin version.[3] This has been reprinted in a revised state by Roensch, together with a Latin version of Dillmann's text. The work of this meritorious scholar is accompanied with learned notes and exhaustive dissertations; and Dr Sal. Rubin has taken the trouble to translate it into Hebrew, with an introduction and notes, Wien. 1870. See Treuenfels in the *Literaturblatt des Orients*, 1846; Beer's *Das Buch der Jubiläen und sein Verhaltniss zu den Midraschim*, 1856; Jellinek, *Bet ha-Midrasch Sammlung kleiner Midraschim und vermischter Abhandlungen aus der älteren Jüdischen Literatur*, 1853-1855; Frankel in the *Monatschrift für Geschichte und Wissenschaft des Judenthums*, 1856; Roensch, *Das Buch der Jubiläen oder die kleine Genesis, u.s.w.*, 1874.

The *Life of Adam*, adduced by Syncellus three times with the words ὁ λεγόμενος Βίος Ἀδάμ, seems to have been identical with the book of Jubilees, or perhaps a part of it. If the latter, it may have been another recension, enlarged and modified in various respects.[4]

The *Book of Adam's Daughters, Liber (qui appellatur) de filiabus Adæ sive Leptogeneseos*, mentioned in Gelasius's decree about authentic and apocryphal books, also appears to be the same as the Jubilees.[5]

4. *The Assumption* or *Ascension of Moses*, Ἀνάληψις Μωυσέως, is a prophecy of the future relating to Israel, put into the mouth of Moses, and addressed to Joshua just before the great lawgiver died. Founded upon the book of Deuteronomy, it is brief and unpoetical. But it seems to have been large at first, for according to Nicephorus, it consisted of 1400 stichs, while the Jubilees had only 1100.[6] The work is an appropriate sequel to the Jubilees, but it seems to have proceeded from a different writer, though he lived at the same time. Internal evidence points to its composition after the death of Herod the Great, and before the destruction of Jerusalem. In the third chapter Pompey the Great is clearly depicted; but there is no trace of Jerusalem's overthrow. The author was a Jew who wrote in Hebrew or Aramæan, and his production was afterwards translated into Greek and Latin. We need not assign him to any other place than Palestine, though Fritzsche conjectures that Rome was his abode. Fragments of the Latin version were first edited from a palimpsest at Milan by Ceriani. The version is by the same hand as that of the Jubilees, for both are found in one MS. and agree in character. The translator may have, therefore, taken the two for the work of the same author. After Ceriani, it has been published by Fritzsche. Hilgenfeld has tried to put it into Greek. The same has been done by Volkmar, Schmidt, and Merx. The ancients believed that Jude borrowed from this work his statement as to the dispute between Michael and the devil about the body of Moses. See Ceriani, *Monumenta Sacra et Profana*, tom. i. fascic. 1; Hilgenfeld, *Novum Testamentum extra canonem receptum*, fascic. i. 1866; *Messias Judæorum*, 1869; Volkmar, *Handbuch zu den Apokryphen*, Band 3, 1867; Schmidt and Merx in *Archiv für wissenschaftl. Erforschung des A. T.*, 1868; Fritzsche, *Libri Apocryphi Veteris Testamenti Græce*, 1871.

5. *Apocalypse of Moses*, whose proper title is Διήγησις καὶ πολιτεία Ἀδὰμ, ἀποκαλυφθεῖσα παρὰ θεοῦ Μώυσῇ τῷ θεράποντι αὐτοῦ, διδαχθεῖσα παρὰ τοῦ ἀρχαγγέλου Μιχαήλ, contains an account of the formation of Adam and Eve, their fall, Seth's dialogue with his mother about Adam, and the disposal of the latter's body beside that of Abel. This work was first published in Greek by Tischendorf from four MSS. It was afterwards accurately edited from one of these (D in the Ambrosian library at Milan) by Ceriani. But this text is incomplete, wanting chapters xviii.-xxxv. Tischendorf thinks that Greek is the original, and that its date is about the time of Christ, but it is probably later, though certainly not mediæval, as Dillmann supposes. The λεπτὴ γένεσις was thought by some, perhaps also by Syncellus and Cedrenus, to have been the same as the *Apocalypse of Moses*, and was so called, but it is not. Both, however, are of like character. The *revelation* is said to have been made to Moses when he received the tables of the law and was instructed by the archangel Michael. Tischendorf, *Apocalypses Apocryphæ*, 1866; Ceriani, *Monumenta Sacra et Profana*, v. i.; Roensch, *Das Buch der Jubiläen*, 1874.

6. *The Sibyllines.*—The rise of Jewish apocalyptic literature of a sibylline character probably dates soon after Alexander the Great, when Judaism began to look with a spirit of philosophic inquiry into Greek and Oriental literature, attaching itself to such elements as seemed congenial. A composite product was the result. The Alexandrian Jews were the first to adopt this course by fusing the remnants of Greek sibyllism with their native prophecy. The former seemed to them an indication of an Adamic or Noachic religion which had filtered into heathenism notwithstanding its polytheism. It was a species of natural prophetism, distinct from the priestly oracles, of a more ancient and higher type, in which Jewish gnosis could discover a point of contact, amid its endeavours to trace the pre-Abrahamic religion in the most enlightened Hellenism. As Noah was thought to be the second great progenitor of humanity, who represented the primitive theocratic religion before its division and corruption, the sibyl was his daughter, prophesying of the tower of Babel, and exhorting the people to worship the true God. Her voice was predominatingly threatening, like that of the heathen sibyl, foreshadowing the downfall of paganism. Anti-theocratic kingdoms and cities must be overthrown. There is but one religion, the old Noachic one, which even the heathen sibyl darkly echoed, and her utterances can only be interpreted aright in their relation to the world's history by the Jewish sibyl. Thus Jewish gnosis found support in Hellenism. After using the method and form of the latter in the sibylline oracles, it drew them into a higher region. Uniting them with theosophy and history, it spiritualised them. The prophetic spirit was discerned in the cultus of heathenism, stripped of priestly and polytheistic phenomena. But it was still the main object of the sibyllines to combat heathenism itself, by exposing its idolatry and opposition to the truth, to anticipate its total destruction at the advent of Messiah.

Under this general name there exists a collection of oracles said to proceed from the sibyl, in which Jewish ideas are promulgated and recommended to the Gentiles. The contents, however, are of a mixed character. Instead of a connected whole written by one person at a specific time, we have a heterogeneous assemblage of materials, Jewish, Christian, and heathen, of earlier and later origin, which must be separated and sifted before they can be assigned to their respective origins.

Books i., ii., iii. 1–96 are late. The first begins with the creation and fall of man, enumerates the six races, and characterises them, the first after Noah falling in the golden age. Christ is described in His miracles, sufferings, death, resurrection, and ascension; the apostles, and the cessation of prophets. The Hebrews will be oppressed by a Roman king, and be scattered abroad after the destruction of Solomon's temple. The description is continued in the second book. The world will be shaken throughout, and especially will heathen Rome be destroyed at the time of the tenth race. The whole piece is evidently Christian, for the eschatological ideas rest upon Matthew xxiv., xxv. Hellenic mythology and Hebrew tradition are intermixed with the author's utterances. The date is obscure. Bleek, with whom Lücke agrees, assumes the 5th century. There are, indeed, late views in the books, such as Christ's descent into hell to preach the resurrection, the worship of the Virgin, the intercession of the saints for a class of the condemned. It is also true that millennarianism does not appear, and that no Christian writer of the first four centuries cites them. Still the 5th century is too late. We prefer the second half of the 4th. Ewald assigns about 300 A.D.

The *third* book, taken as a whole, is the oldest portion, at least verses 97–828. It enumerates the kingdoms of the world that followed one another, emphasising the Hebrew one in particular, and mentioning the Roman. Woes are pronounced upon various cities and lands, and the appearance of Messiah is depicted, accompanied with the punishment of the wicked, the downfall of all worldly kingdoms, the conversion of the heathen, and the restoration of Judah to more than former splendour. As the destruction of Carthage by the Romans is alluded to, the date must be after 146 B.C. Various indications point to 124. There is little doubt that the writer was an Alexandrian Jew, whose hopes of a personal Messiah were feeble and vague, for after touching upon a king sent by God from the sun who will put an end to war, and under whose sway Israel will enjoy abundant prosperity, he paints the golden age again without mentioning the king.[1]

The *fourth* book, which is but a short poem of less than two hundred lines, arranges history according to twelve ages, terminating in the Messianic one. The writer's descriptions are general. He evinces no decided Jewish sympathies, nor does he utter ideas distinctively Christian. Sinful heathenism in an indefinite way is the chief object of his veiled descriptions. Hence Friedlieb makes him a Jew; Ewald, a Christian. The passages which have been supposed to show either his Christian or Jewish tendencies[2] are hardly decisive as to the one or the other; and the interpretations of them by Lücke are somewhat strained in support of the strong statement about the Christian character of the contents generally, with which he begins his sketch of the fourth book. Probably he was a Jewish Christian who came out of an Essene circle. The date of his oracle is somewhat later than that of the Apocalypse, since the destruction of the temple is presupposed as well as the eruption of Vesuvius, 79 A.D. The return of a matricidal emperor from beyond the Euphrates to overthrow Rome is also expected. Such allusion to Nero, which is a prominent feature in the Apocalypse, and a few other particulars, incline us to assume Christian authorship, though the absence of evangelical ideas marks a stage not far beyond Judaism. Yet the writer rejects sacrifices. The date may be about 80 A.D.

The *fifth* book presents great difficulty both in separating the component parts, and in assigning them to Jewish or Christian authorship. The absence of ideas characteristic of Judaism or of Christianity marks the poem. Nor is it easy to discover any internal connection, so that the whole might be attributed to the same authorship. The religious views of the author or authors are vaguely expressed. The first part, *i.e.*, 1–51, appears to be of Christian, the rest, *i.e.*, 52–530, of Jewish origin. The former describes in prophetic language the series of Roman emperors from Julius Cæsar to Hadrian. In this way we are brought to the end of Hadrian's reign as the date, about 138 A.D. The second part, which expresses among other things the hope of a temple to be erected in Egypt, in which sacrifices should be offered, and the people of God should enjoy Messianic happiness, points to a Jew of Alexandria living after the destruction of the temple at Jerusalem, about 80 A.D.

The *sixth* book contains a short hymn to Jesus the Son of God, touching upon His doctrine, miracles, and death, with a curse on the Sodomite land which platted His crown of thorns. It is curious that the fire at Jordan on the occasion of the baptism of Jesus, and the representation of the dove, vary from the canonical Gospels, though the former appears in the Gospel of the Hebrews. Something of a Gnostic element shows itself here.

The *seventh* book is a fragmentary collection of oracles loosely connected. The contents are varied. Several pieces treat of Christ; several of the oracles are threatening, some are of the nature of hymns. The baptism at Jordan is mentioned in a peculiar way;[3] and a strange sacrificial rite is recommended.[4] The allusion to the Persians reigning is indefinite; but it is all the historical evidence that bears on the date, which seems about 160 A.D.; though Alexandre puts it between 233 and 235 A.D.[5] As there is a tinge of Gnosticism in the book similar to that of the sixth, they may have proceeded from the same person. He was a heretical man, as Alexandre supposes; but whether he was a Jewish Christian is uncertain.

The *eighth* book contains a prophecy of the judgment of the world. Rome is coming at length to an end. There is also a summary of the history of Jesus, His life, sufferings, and resurrection. The writer commences with Hadrian, to whom he gives three successors of his house. He is also acquainted with the king of another house, Septimius Severus, in whose days, 948 of Rome, the end comes. The date is therefore 211 A.D. It is curious that Antichrist Nero is here made to come with the third from Hadrian, viz., Commodus. In this oracle occurs the celebrated sibylline acrostic, the initial letters of thirty-four lines (verses 217–250) representing Ἰησοῦς Χρειστὸς Θεοῦ υἱὸς σωτὴρ σταυρός. Verses 361–500 are of earlier origin. They contain various fragments of prior poems. It is noticeable that a historical insertion about the birth of Jesus Christ from the Virgin occupies an unsuitable place, having been the product of a late time, when the dogma about the mother of God was developed. With this exception the second part of the book belongs to the 2d century. The whole is thoroughly Christian.

Books xi.–xiv. were discovered in MSS. at Milan and Rome, and published by Mai, in his *Veterum Scriptorum nova collectio*, tom. iii. p. 202, *et seq.* They are of Christian origin, and from Egypt. It is true that the Christian element appears but little. The writer used the preceding books and heathen oracles besides. The date is uncertain, but cannot be earlier than the 5th century. The eleventh book surveys the history of kings and people, till the death of Cleopatra and the end of the Egyptian kingdom; the twelfth recounts the Roman emperors from Augustus till the death of Alexander Severus; the thirteenth continues the history from Alexander Severus till

the reign of Odenatus, and the fourteenth brings down the sketch to Aureolus. The names of the emperors and rulers are partially disguised, and eventually become unrecognisable. See Friedlieb, *Oracula Sibyllina*, 1852; Alexandre, *Oracula Sibyllina*, 1841, 1856; and Ewald, *Ueber Entstehung, Inhalt, und Werth der sibyllinischer Bücher*, 1858.

7. *The Apocalypse of Baruch.*—In this rhetorical production Baruch receives revelations respecting the future of Israel. Though Jerusalem has been destroyed by the Romans, and the calamities of the chosen people seem excessive, the prophet is comforted with the hope of better times, since the Messiah will come shortly to set up his kingdom after the Roman one has been destroyed. Then will be the judgment and the consummation; sinners will be punished, and the righteous rewarded. Part of this production, viz., the epistle of Baruch to the nine tribes and a half (chapters lxxviii.–lxxxvi.), was published in the Paris and London Polyglotts in Syriac and Latin. The Syriac was again edited more correctly by De Lagarde. Whiston translated the Latin into English; and he has been followed by Jolowicz, 1855. The whole book was published from a Syriac MS. in the Ambrosian library by Ceriani, first in a Latin translation[1] and then in the Syriac itself.[2] The Latin is reprinted with a few emendations by Fritzsche. It was written after the destruction of Jerusalem, how long it is difficult to say. The author was acquainted with the Book of Enoch and the Apocalypse of Esdras, for he has many passages which are echoes of sentiments contained in them. He has also later Jewish legends, which point to the 2d century of the Christian era as that in which he wrote; and there is little doubt that Greek was the original. Langen[3] thinks that the author was a Palestinian. From its length and wordiness, with the absence of poetic spirit, the perusal of the document becomes wearisome.

II. Christian Apocalyptic.

Christians followed the example of the Jews in using the sibyl as a vehicle of their ideas. Besides referring to the past, which they did mainly with reference to the person and work of Jesus Christ, they looked forward to the destruction of the world-power, and the consummation of all things at the second coming of Christ. They employed to a considerable extent both Jewish and heathen documents, interpolating or modifying them not very strongly. Often content with non-Christian sources, they adapted them but slightly, so that the ideas peculiar to Christianity shine forth dimly. The prophetic form of the Apocalypse does not demand the enunciation of doctrine, but rather a general indication of historic events, or the threatening announcement of destruction to the enemies of God. It deals with the utterance of principles exemplified by kingdoms and their rulers.

1. *The Sibyllines.*—We have already seen that books i., ii., iii. 1–96, iv., v. 1–51, vi., vii., viii., xi.–xiv., belong to this head, though they incorporate Jewish as well as heathen pieces with small adaptation.

2. *The Apocalypse of Esdras.*—This Greek production resembles the more ancient fourth book of Esdras in some respects. The prophet is perplexed about the mysteries of life, and questions God respecting them. The punishment of the wicked especially occupies his thoughts. Since they have sinned in consequence of Adam's fall, their fate is considered worse than that of the irrational creation. The description of the tortures suffered in the infernal regions is tolerably minute. At last the prophet consents to give up his spirit to God who has prepared for him a crown of immortality. The composition is feeble and tame, a poor imitation of the ancient Jewish one. There are no internal marks of date in it. It may belong, however, to the 2d or 3d centuries of the Christian era. Tischendorf published the Greek text for the first time in his *Apocalypses Apocryphæ*.

3. *The Apocalypse of Paul.*—This work contains a description of the things which the apostle saw in heaven and hell. The text, as first published in the original Greek by Tischendorf, consists of fifty-one chapters, but is imperfect. The narratives descend to minute particulars, and possess no force or poetic power. Imitated from the Revelation of St John, their great inferiority is apparent. Internal evidence assigns it to the time of Theodosius, *i.e.*, about 390 A.D. Where the author lived is uncertain. Dr Perkins found a Syriac MS. of this Apocalypse, which he translated into English, and printed in the *Journal of the American Oriental Society*, vol. viii. This version is an enlarged and exaggerated edition of the Greek, which it supplements and illustrates. See Tischendorf's *Apocalypses Apocryphæ*.

4. *The Apocalypse of John* contains a description of the future state, the general resurrection, and judgment, with an account of the punishment of the wicked, as well as the bliss of the righteous. It appears to be the work of a Jewish Christian, for the bodily appearance of Antichrist is derived from Jewish sources; and there are numerous quotations from the Old Testament, especially from David. The date is late, for the writer speaks of the "venerable and holy images," as well as "the glorious and precious crosses and the sacred things of the churches,"[4] which points to the 5th century, when such things were first introduced into churches. We cannot put it earlier than the 5th. This Apocalypse was first published by Birch,[5] but incorrectly; afterwards by Tischendorf. The Greek appears to be the original. It is a feeble imitation of the canonical Apocalypse, devoid of literary value, and with the marks of a corrupted Christian age on its face.

5. *The Apocalypse of Peter* contains a narrative of events from the foundation of the world till the second advent of Christ. The book is said to have been written by Clement, Peter's disciple. This Arabic work has not been printed, but a summary of the contents is given by Nicoll in his catalogue of the Oriental MSS. belonging to the Bodleian.[6] There are eighty-eight chapters. It is a late production; for Ishmaelites are spoken of, the Crusades, and the taking of Jerusalem.

6. *The Revelations of Bartholomew.*—In the year 1835, Dulaurier[7] published from a Parisian Sahidic MS., subjoining a French translation, what is termed a fragment of the apocryphal Revelations of St Bartholomew, and of the history of the religious communities founded by St Pachomius. After narrating the pardon obtained by Adam, it is said that the Son ascending from Olivet prays the Father on behalf of His apostles; who consequently receive consecration from the Father, together with the Son and Holy Spirit—Peter being made archbishop of the universe. The late date of the production is obvious.

7. *The Apocalypse of Mary*, containing her descent into hell, is not published entire, but only several portions of it from Greek MSS. in different libraries, by Tischendorf in his *Apocalypses Apocryphæ*.

8. *The Apocalypse of Daniel* has been published only in part (a little more than the half), by Tischendorf from Greek MSS., in St Mark's, Venice, and in Paris. The date of the document is determined by the monarch going to Jerusalem to deliver up his kingdom to God, and being succeeded by his four sons, who reside in different and distant cities.

9. *The Ascension and Vision of Isaiah.*—The first portion of the work called the Ascension of Isaiah in the Ethiopic text, gives an account of Isaiah's being put to death by the saw, under the reign and at the command of Manasseh. The prophet had had a vision respecting Christ, His crucifixion and ascension, as well as of the general apostacy which should take place in the early churches, of the descent of Berial in the form of a matricidal king, the duration of his reign, the descent of the Lord from heaven to destroy the wicked, and cast the ungodly into the fire. For this vision and prophecy Isaiah is condemned, and dies the death of a martyr (chapters i.–v.) The second part (chapters vi.–xi.) is essentially the same as Isaiah's vision in iii. 14–iv. 22. The prophet is transported in an ecstatic state into the seven heavens successively, and describes what he sees in each, the chief object being Christ himself. It is not the future of Christianity and of the world which fills the mind of the seer, but the past, the first advent of Christ. The two divisions form distinct works. The first is based on the Jewish legend of Isaiah's martyrdom, and may be merely the Christian expansion of a Jewish writing embodying it. Indeed, with the exception of the Christian interpolations (i. 5, iii. 13–iv. 22), the whole is Jewish. Both Tertullian and Origen knew the martyrdom part of the document. The date must, therefore, be the 2d century. The second, or the *Vision* of Isaiah, properly so called, has a Gnostic colouring. Its christology bears a Docetic stamp. As it presupposes an acquaintance with the first it may have originated in the early part of the 3d century. Epiphanius speaks of it, and gives an extract.[1] Laurence published the Ethiopic text, with a Greek and Latin version, in 1819. The Greek original is lost; and the Latin version, published at Venice in 1522, and again by Gieseler in 1832, is of late origin. Fragments of an older one were printed by Mai in his *Veterum Scriptorum nova collectio*, p. ii. 1828. Jolowicz translated it into German, 1854. See Lücke's *Versuch einer vollständigen Einleitung in die Offenbarung des Johannes, etc., das erste Buch.*

10. *The Shepherd of Hermas.*—This production belongs in a certain sense to the present class of writings, and is usually reckoned among the apostolic fathers. It is not, however, apocalyptic in the proper acceptation of the epithet, because it wants the form. The apocalyptic idea has a different phase. (See Apostolic Fathers.) The same remark applies to—

11. *The Testaments of the Twelve Patriarchs.*

Many apocalyptic writings, both Jewish and Christian, are mentioned in ancient works of which nothing is now known. Time has swept them away beyond recovery. It would be useless to collect the scattered notices of them. Such as wish to see these notices may consult the articles of Dillmann and Hofmann, in the 12th volume of *Herzog's Encyklopædie*, Lücke's *Einleitung*, and the Prolegomena to Tischendorf's *Apocalypses Apocryphæ*, where he will find references to other works. Since the very able treatise of Bleek and the valuable publications of Gfrörer, which were followed by the masterly review of the whole subject in Lücke's second edition, the literature has greatly increased. Hilgenfeld and Volkmar, Ewald and Dillmann, Ceriani and Langen, Fritzsche, Gutschmid, Merx, and others, have thrown welcome light upon it.

The line between *Apocryphal* and *Apocalyptic* literature is not exact. The works now described are those which properly belong to the latter, and are extant, or have been published, if not entire, at least partially. Notices of many others lost or hidden occur in various sources and catalogues of MSS. belonging to public libraries. The apocalyptic idea passed into the life and belief of the church. It became an element of dogma and of morals, finding expression in works somewhat different from the proper apocalyptic. Taking a millennarian direction, using the typical extensively, developing eschatological ideas more or less fantastic, the apocalyptic element receded before other conceptions to which it had given rise. These, indeed, did not suppress it; they merely shaped and developed it into other forms, widening the sphere of its action, and giving it more realism. (S. D.)

[1] *Hæres.*, 67, 3, vol. ii., p 175, ed. Migne. See also *Hæres.*, 40, 2.

APOCRYPHA. This term is a Greek word meaning *hidden, secret*. It occurs, for example, in Col. ii. 3, "In whom are *hid* all the treasures of wisdom and knowledge," and elsewhere in the New Testament. It is first found applied to writings in Clemens Alexandrinus, *Stromata*, iii. c. 4. When applied to writings (ἀπόκρυφα sc. βιβλία) the name may be supposed to have first expressed the nature of their contents; the writings were *secret*, embodying an esoteric teaching, profounder than that contained in the ordinary books of the system, and unknown to the ordinary people who professed it. Such writings were held to exist in connection with almost all the ancient systems of religion.

From the nature of the case, the same word might very well describe such writings further, either in respect of their *use* or in respect of their *origin*. In use these writings were, of course, like the doctrines they contained, private and secret; they were not read in general meetings, and did not belong to the publicly recognised books of the system. Only some were admitted to the knowledge of them. That which formed the subject of public reference and instruction was the general doctrines of the system, while these peculiar and more recondite works were at most brought forward on rare occasions. And naturally the same secrecy which hung over their use generally also shrouded their origin. In some cases this might be a real mystery; the books were sometimes of ancient and uncertain date, and their authorship unknown. But oftener the mystery was fictitious, created for the purpose of securing respect for the doctrines inculcated in the writings, which themselves were forgeries of very recent times. Works of this kind were of very common occurrence in the East during the centuries immediately preceding and following the birth of Christ. In order successfully to float them and give them impulse, they were generally launched under some ancient and famous name; and books existed, bearing to be the productions of almost every renowned patriarch or sage from Adam downwards. Even when sent out anonymously, and of an historical rather than a doctrinal character, the scene of their narratives was laid in far back times, and famous personages were introduced acting and speaking, the design being to recommend to the living generation the conduct pursued or the sentiments expressed by the ancient hero or saint.

The term *Apocrypha* appears in this way to have passed through several stages of meaning, and from expressing a meaning good, or at least neutral, it came at last to have a very bad sense, differing very little from *spurious*. From the use of the word in ancient writers it does not appear that this progress from a good or indifferent to a bad sense was a matter of time, for the indifferent and bad meanings of the word seem to have existed side by side. Some ecclesiastical writers divide the sacred books into three classes,—recognising first, some that are canonical; second, some that are not canonical, but of inferior value, profitable to be read for moral uses, but not to be founded on for doctrine—to this class the name *ecclesiastical* was sometimes given; and third, some that are apocryphal. Other writers know of only two classes, embracing both the second and third classes of the former division under the name apocryphal. This difference indicates a milder and a severer use of the term.

Besides those books known distinctively as the Old Testament Apocrypha, a very large number of apocryphal writings were in existence in the early centuries of our era. Some of these are still extant, but many of them have perished, or are known only through MS. translations lying in our great libraries. Our only information regarding many of them is derived from references to them in ecclesiastical writers. These references are sometimes so general that we cannot be sure whether the book referred to was a Jewish or a Christian production. By far the largest number even of those bearing Jewish titles were works by Christian writers. Of the extant writings of this class the most important are fully treated in the article APOCALYPTIC LITERATURE immediately preceding. In addition to those discussed there may be mentioned the very interesting collection of hymns called the *Psalms of Solomon*. This small work consists of eighteen poems of varying length, to appearance all by one writer, and existing now only in Greek, though in all probability originally written in a Shemitic dialect. These poems arose in a time of trouble to the Jewish people, most probably in the Greek persecution, and they were designed to sustain the nation under its trials, partly by moral considerations, but chiefly by picturing the certain glories of the Messianic kingdom. The hymns are remarkable no less for the vigour of their poetry than for the fervid theocratic hopes and distinct faith in the resurrection and kindred doctrines which find expression in them. O. F. Fritzsche has appended this little work, along with other select *Pseudepigraphi* of the Old Testament, to his edition of the Old Testament Apocrypha.

APOCRYPHA OF THE OLD TESTAMENT.—The books bearing this name are not contained in the Jewish or Palestinian Canon, *i.e.*, in the Hebrew Bible, but in the Alexandrian Canon, *i.e.*, in the Greek translation known as the Septuagint. Considerable obscurity hangs over the date and the circumstances of the close of the Hebrew Canon, and the principles which guided the collectors in their selection of books to be embodied. It is most probable that the *three* divisions referred to in the New Testament, of law, prophets, and writings (Psalms) are of ancient origin; that the first two divisions were closed while prophetic men were still living, that is, considerably anterior to the close of the Persian period, while the third still remained open; and that at whatever time the third was closed, the books added to it were added under the impression that they were books composed before the succession of Prophets had ceased. This is the view expressed by Josephus (*Con. Ap.*, i. 8), and may be considered the general Jewish tradition regarding all books in the Hebrew Canon.

With the Greek or Alexandrian Canon the case was very different. This was, properly speaking, not an ecclesiastical, but a literary collection at first, for the tradition that it was commenced under the auspices of Ptolemy Philadelphus cannot be altogether set aside. At first only the books of Moses and perhaps Joshua were translated, the interest felt in the book being confined to the law. Only gradually and at intervals other books were added, for the translations are not only by different hands, but of very different dates. But it is evident that the collection was formed under the guidance of a principle quite different from that which guided the Palestinian collectors. The feeling in Palestine was that prophecy had ceased (1 Macc. ix. 27, comp. ch. xiv. 41), and no books were held worthy of a place in the Canon which were composed after the succession of prophets had come to an end. In Egypt this theory did not prevail, or rather another theory seems to have prevailed. The doctrine of the *Wisdom* which appears in Proverbs, ch. i.-viii., received a fuller development in successive ages even in Palestine, and naturally much more in Alexandria, where the speculative Jews came under the influence of Greek thought. This *Wisdom* is spoken of in a way which at times almost identifies it with the Spirit of God, and at other times almost with the *Logos* or Word. But at any rate this divine Wisdom is all-pervading, and subject to no interruption in the constancy of its influence. The famous passage, Wisdom of Solomon, ch. vii. 22, *f.*, in which the attributes of wisdom are counted up to the number of twenty-one, speaks of her as "going through all things by reason of her pureness," and at last says of her, that "in all ages entering into holy souls she maketh them friends of God and prophets." The particularism of Judaism gave way in Alexandria before the universalistic principles of Western speculation. Prophecy was the product of the Wisdom, and Wisdom was like a subtle element, all-pervasive and incessant in its influence; and consequently a break in the line of prophets, or any distinction between the productions of one age and those of another except in degree, was hardly to be conceived. Thus to the Alexandrian the varied Jewish literature of the post-prophetic times was precious as well as the books that were more ancient, and he carefully gathered the scattered fragments of his national thought, as far as they were known, within the compass of his Canon.

The following books form the Apocrypha of the English Bible. They are given in the order in which they stand there:—1. I. Esdras. 2. II. Esdras. 3. Tobit. 4. Judith 5. The additions to the Book of Esther. 6. The Wisdom of Solomon. 7. The Wisdom of Jesus, the son of Sirach, or Ecclesiasticus. 8. Baruch. 9. The Song of the Three Holy Children. 10. The History of Susanna. 11. The History of the Destruction of Bel and the Dragon. 12. The Prayer of Manasses, king of Judah. 13. The First Book of Maccabees. 14. The Second Book of Maccabees.

A few statements may be made regarding the general characteristics of the Apocrypha.

1. These books are of very great interest and value as a reflection of the condition of the fragments of the scattered nation, and of the feelings and aspirations which they cherished for a period of several hundred years, and in all the chief countries of the world. Some of the books, such for example as *Tobit*, belong to the Persian period, and were composed in the East, in Babylon or Persia, and describe the external life as well as the feelings and hopes of the exiles there; others arose in Palestine, such as *Ecclesiasticus*, and reflect the condition of life and the shades of religious speculation in the home country; while others, such as the *Wisdom of Solomon*, originated in Egypt, and afford means of estimating the influence of Greek thought upon the native doctrines of the Old Testament; and perhaps in the *2d Esdras* there may even be detected traces of Christian influence. The broad undivided stream of Old Testament doctrine and hope breaks at the era of which we are speaking into three channels. The largest, and that which best preserves its primary directions continues to run in Palestine, diverging to some extent, and widening under the contributions which time and a very chequered experience and reflection made to it while on each side of this another runs, one on the east and one on the west, directed and partly fed by the ideas of Persia and Greece respectively. To a certain extent the streams reunite further on, and pour their united contributions into the great sea of Christian thought. The central stream

is, of course, the most interesting, although to estimate it properly the books of the English Apocrypha are quite insufficient, other works belonging to the same region must also be taken into account, such as the great *Book of Enoch*, and several more. The two collateral currents are also of extreme interest although it is far from easy to analyse their waters, and say with assurance what elements belong to the primary Old Testament sources and what are local contributions. Many have discovered traces of Persian ideas even in the canonical books of the Old Testament, particularly in the doctrine of angels in the later books, but the trustworthiness of such discoveries may be very fairly questioned. At the same time, there either is, in the book of *Tobit*, an advance absolutely on the Old Testament doctrine of angels and demons, or there are traces of a method of interpreting the history in Gen. ch. vi., and a carrying out of the method to further consequences, which are both unknown to the canonical Scriptures (below No. 3). And if in the Alexandrian *Wisdom of Solomon* a progress directly *in advance* of what is found in Prov. viii., on the doctrine of *Wisdom*, may be justly contested, there is certainly what may be called a progress *round about*, the ideas about Wisdom are expanded and placed in new lights, and made to enter into new relations, in such a way that a general approximation to the New Testament doctrine of the Logos is the result. But in general, as a means of estimating the changing shades of feeling, the rise and fall of hopes, or rather the steady glow of a hope which no hardship could extinguish, the efforts to accommodate faith to circumstances and hold it fast in spite of all that was against it, in a word, as a means of estimating the inner life of a most interesting people in the very crisis of their history, the apocryphal books are invaluable. No more beautiful picture of piety and disinterested benevolence and patriotic warmth could be seen than is presented in the book of *Tobit;* neither could religious zeal and courageous, even almost reckless, patriotism, easily find higher expression than in the first book of *Maccabees*, or even in the unhistorical tale of *Judith;* while the under current of observant thoughtfulness, that contemplates but hardly mixes in life, runs in a deep, if calm and passionless stream in the proverbs of the Son of Sirach. At no time was the nation idle. A people that had conceived such hopes, hopes which at last culminated in Christianity, could not be idle or even anything less than restless and turbulent. There is no form of deed celebrated in the ancient history of the people that they did not try to reproduce, and no form of literary composition which, in those mournful centuries so full of oppression, they did not strive to imitate, with an inextinguishable life and hopefulness. This last fact, perhaps, might furnish the means of a classification of the books different from that suggested above, and similar to the division usually adopted in the Old Testament Scriptures. (1.) Historical, such as 1*st Maccabees*, although most that assume the historical form, such as *Judith*, are simple romances, and can be used only as an index of ideas and feelings, not in proof of facts; while others, like *Bel and the Dragon*, are completely fabulous. (2.) Prophetical, such as *Baruch* and 2*d Esdras*. In these the religious hopes of the people are most fully exhibited; for example, the Messianic expectations. Fully to understand these, however, other works, such as the book of Enoch, not contained in the recognised Apocrypha, have to be included. The prophetic literature almost always assumes the form called apocalyptic. (3.) Philosophical, or books coming under the Hebrew name of Wisdom. Here belong the *Son of Sirach*, the *Wisdom of Solomon*, to which must be added others not included in the English Apocrypha, *e.g.*, the *Psalter of Solomon* and 4*th Maccabees*.

2. It has already been said that the Hebrew or Palestinian Canon was formed on the feeling that, before the close of the Persian period, the succession of prophets ceased. It is too evident that this feeling was a true one. The restoration from exile was little more than an external form with almost no real life within. The new community was feeble in the extreme. It had no productive power of its own. It must fall back entirely upon the past. The most and the best it could do was to conserve the forms and, if possible, the spirit of what was ancient. But the spirit, which should also have been its own, was lacking. Hence everything in the new state was mechanical and rigid. Even the canonical writings of this epoch, such as Chronicles, are mere compilations. And the further off from the ancient times the people removed, the stiffer and more mechanical they grew. No doubt a certain energy was infused into the people at various epochs, particularly in the Maccabean struggles, yet even then there is a certain stiffness and awkwardness both in the acts and writings of the time, as when old age girds itself up for deeds to which it is no longer equal. This loss of the prophetic and productive power, and the consciousness of the loss, explains most of the characteristics of the apocryphal literature. For example, there is wanting in it, even where most genial and natural, that original freshness which is so charming in a book like Ruth; and even the proverbial philosophy of the Son of Sirach, instead of bubbling up in living springs, as in Solomon, often appears forced and unwilling in its flow; while in others of the philosophic books there is an elaborate redundancy of language, and a floridness of rhetoric, most unlike the simplicity and terseness of the ancient Wisdom.

Again, the consciousness of the loss of real creative power and complete dependence on the past explains another peculiarity of these books—their pseudonymous character. They do not come forth as the products of their own time, and with the authority of their real authors; they are transferred into the distant past, into the stirring times of living Israelitish history, and their authors are made to be the great historic names of the nation. The Alexandrian philosopher calls his work the *Wisdom of Solomon*. The author of *Judith* pitches his romance in Assyrian times. In this way effect is sought, and truths and actions are commended by an authority that is felt no longer to exist.

A defective sense of truth very naturally becomes more serious. To compose a work in what is believed to be the spirit of some ancient sage or hero, and put it forth under his name, may seem a venial wrong. Yet in an uncritical age it often led to very unfortunate results. Neither might it seem greatly amiss to advocate a cause and recommend an action by exhibiting ancient names uttering similar sentiments, or following the same course, and in an age like our own little evil might follow. Yet the next step downward is the direct forgery of documents, such as the Letters of Artaxerxes, which we find in the additions to Esther, or the Epistles at the beginning of 2 Maccabees. The apocryphal books everywhere demonstrate that all true historic consciousness was deserting the people; and though we may gather truth out of the Apocrypha, it is rarely truth directly stated, but reached by our own inferences from the character of the writings and the objects the author plainly enough had in view.

3. One of the most interesting inquiries connected with the Apocrypha is, as to the advance in doctrine and opinion over the Old Testament to be found in it, and its nearer approach to the New Testament. This is a very delicate inquiry, although the existence of a certain advance cannot be denied, and is most certainly to be expected. For the church did not cease to exist in these centuries, and if she was to appearance barren, yet in fact she was maturing into life the seed which she had already conceived

Parallel to this inquiry, or almost a part of it, runs another, viz., that as to the origin and development of the *parties* which figure so prominently in the pages of the New Testament. All these parties date in their germs from the times of the Restoration, or those not greatly posterior, and may roughly be divided into *two*—those who rigidly adhered to their native Judaism, of whom the Pharisees may be considered the chief representatives; and those who ethnicised, either attaching themselves exclusively to Gentile culture, or combining elements of foreign thought and worship with their native faith, the most prominent sect in this class being the Sadducees. We may expect to come in the Apocrypha upon many traces of such diverging opinions. A specimen here and there will illustrate the position of things in these books.

The want of real life at the time of the Restoration, and the consequent mechanical adherence to ancient forms, was the direct parent of the Pharisaic morality so well known. Already this appears in Tobit. The Pharisee, who went up to the temple to pray, might almost have gathered the elements of his prayer from this book. "Prayer is good with fasting, and alms, and righteousness. . . . . For alms doth deliver from death, and shall purge away all sin" (ch. xii. 8, comp. ch. xiv. 11, and Judith viii. 6, xi. 11, *ff.*) On the other hand, traces of quite a different morality, allied to asceticism, appear elsewhere, as in the statement of Wisdom ix. 15, regarding the body: "For the corruptible body presseth down the soul, and the earthly tabernacle weigheth down the mind that museth upon many things." On the general doctrine of God no advance perhaps was possible. Very lofty things are said by the author of Ecclesiasticus, *e.g.*, ch. xliii. 30, and in many places, but nothing to surpass or even equal what is said in the Old Testament. Perhaps a certain effort is discernible to emphasise the spirituality of God, both directly and by avoiding anthropomorphic images. This effort is far less discernible in the Apocrypha than in the other productions of the same and succeeding ages, such as the Septuagint, the Targums, &c., which are apt to use circumlocutions like the *Word of God*, the *Shekinah*, &c., for God.

As to the doctrine of the Wisdom there is no doubt a certain development of it in these books. But it is doubtful if Wisdom be anything more anywhere than a personification, to which attributes are given that sometimes make it closely resemble the Spirit, and sometimes the Word or Messiah of the New Testament. Certainly the Wisdom is nowhere in these books identified with the Messiah, although the predicates of Wisdom are applied to the Messiah in the New Testament. (Comp. Wisdom vii. 26, with Hebrews i. 3, and the general descriptions of Wisdom, Wisdom ix. 4, 9, *ff.*, vii. 12, *ff.*, &c., Ecclesiasticus, ch. i.) The doctrine of the existence of spirits intermediate between God and man, through whom God's providence is often executed, is certainly found in the Old Testament. These spirits seem mostly benevolent, although there is one whose office it is to accuse and detract, called *Satan*, whose character seems evil. This spirit appears formally in the prologue to Job, and in Zech. ch. iii; comp. 1 Chron. xxi. 1. And some have found traces of the belief in evil spirits in the word "Azazel" (Lev. xvi.), as well as in the "satyrs" of Isaiah (xxxiv. 14). In the book of Daniel the doctrine of angels receives a certain addition, inasmuch as—first, the general activity and superintendence of these spirits is indicated by the name given to them of "watchers" (ch. iv. 10, *ff.*); and second, it is intimated that every kingdom has its guardian spirit (Dan. x. 13, 20). The Apocrypha repeats this last idea, Eccles. xvii. 17, and so does the Septuagint on Deut. xxxii. 8. But the angelology of the book of Tobit makes a double step forward—first, in the direction of teaching a hierarchy among angels—"the seven holy angels, ... which go in and out before the glory of the Holy One" (ch. xii. 15, though comp. Dan. x. 13); and second, in assigning special functions to angels, they "present the prayers of the saints," and assume the care of individuals (ch. v. *ff.*) And demonology receives even a more striking though grotesque development. A wicked spirit, named Asmodeus, is represented as falling in love with Sara, daughter of Raguel, and slaying out of jealousy the seven young men to whom she had been successively married, but is at last put to flight by the fumes of the heart and liver of a fish, and bound in chains in the utmost parts of Egypt (ch. iii. 8, vi. 14, viii. 3).

Even more instructive is it to trace the advance towards clearness of the doctrines concerning the state of man. Many times what is implied in the Old Testament is stated with explicitness. For example, "God created man to be immortal, and made him to be an image of his own eternity; nevertheless, through envy of the devil, came death into the world, and they that do hold of his side do find it" (Wisdom ii. 23.) Again, "Of the woman came the beginning of sin, and through her we all die" (Ecclesiasticus xxv. 24). The references given above will suffice to indicate what lines of study may be pursued in the Apocrypha, and what advantages may be expected to be derived from them.

4. The degree of estimation in which the apocryphal books have been held in the church has varied much according to place and time. As they stood in the Septuagint or Greek Canon, along with the other books, and with no marks of distinction, they were practically employed by the Greek fathers in the same way as the other books; hence Origen, Clement, and others, often cite them as "Scripture," "divine Scripture," "inspired," and the like. On the other hand, teachers connected with Palestine, and familiar with the Hebrew Canon, rigidly exclude all but the books contained there. This view is reflected, for example, in the canon of Melito of Sardis, and in the prefaces and letters of Jerome. Augustine, however, *De Doct. Christ.* ii. 8, attaches himself to the other side. Two well-defined views in this way prevailed, to which was added a third, according to which the books, though not to be put in the same rank as the canonical Scriptures of the Hebrew collection, yet were of value for moral uses and to be read in congregations,—and hence they were called "ecclesiastical." Notwithstanding the decisions of some councils held in Africa, which were in favour of the view of Augustine, these diverse opinions regarding the apocryphal books continued to prevail in the church down through the ages till the great dogmatic era of the Reformation. At that epoch the same three opinions were taken up and congealed into dogmas, which may be considered characteristic of the churches adopting them. In 1546 the Council of Trent adopted the Canon of Augustine, declaring "He is also to be anathema who does not receive these entire books, with all their parts, as they have been accustomed to be read in the Catholic Church, and are found in the ancient editions of the Latin Vulgate, as sacred and canonical." The whole of the books in question, with the exception of 1st and 2d Esdras and the Prayer of Manasses, were declared canonical at Trent. On the other hand, the Protestants universally adhered to the opinion that only the books in the Hebrew collection are canonical. Already Wycliffe had declared that "whatever book is in the Old Testament besides these twenty-five (Hebrew) shall be set among the Apocrypha, that is without authority of belief." Yet among the churches of the Reformation a milder and a severer view prevailed regarding the Apocrypha. Both in the German and English translations (Luther's, 1537; Coverdale's, 1535, &c.) these books are separated from the others, and set by themselves; but while in some con-

fessions, *e.g.*, the Westminster, a decided judgment is passed on them, that they are not "to be any otherwise approved or made use of than other human writings," a milder verdict is expressed regarding them in many other quarters, *e.g.*, in the "argument" prefixed to them in the Geneva Bible; in the 6th Article of the Church of England, where it is said that "the other books the church doth read for example of life and instruction of manners," though not to establish doctrine; and elsewhere.

Somewhat bitter controversies have raged over the Apocrypha in recent times. One was carried on in Scotland in 1825 and following years, which had the effect of inducing the British and Foreign Bible Society to employ its funds for the circulation of the canonical Scriptures only. Abundant materials for a history of this controversy may be found in the pages of the *Christian Instructor* for the years just named. More recently a similar controversy has been waged in Germany, where Stier and Bleek and Hengstenberg were found on the side of the Apocrypha, and Keerl with others against. See *Die Apokryphenfrage, mit Berücksichtigung der darauf bezüglichen Schriften Dr Stier's und Dr Hengstenberg's, aufs Neue beleuchtet*, von P. F. Keerl, Leip. 1855. Useful works on the subject are—Fabricii *Codex Pseudepigraphicus Vet. Test.*, Hamb. and Leip. 1713 and 1741; *Libri Apocryphi Vet. Test. Græce*, recensuit et cum Commentario critico edidit Otto Frid. Fritzsche, Lipsiæ, 1871; *Kurzgefasstes Exegetisches Handbuch zu den Apok. des Alt. Test.*, bearbeitet von Dr O. F. Fritzsche u. Dr C. L. W. Grimm, in 6 Lieferungen. Compare also, Ewald, *History of Israel*, vol. v. (trans.) Lond. 1874, Schürer, *Lehrbuch der Neutest. Zeitgeschichte*, Leip. 1874; Langen, *Das Judenthum in Palestina zur Zeit Christi*, Freiburg, 1866; Nicolas, *Des Doctrines Religieuses des Juifs, pendant les 2 siècles antérieurs à l'ère chrétienne*, Paris, 1860. Much information may also be found in the Introductions to the Old Testament, *e.g.*, Davidson's, vol. iii., and in the articles "Apocrypha," "Canon," and those on the individual books in Smith's and Kitto's *Bible Dictionaries* and Herzog's *Encyklopädie.* (A. B. D.)

APOCRYPHAL BOOKS OF THE NEW TESTAMENT.—These may be divided into two classes—those books which were actually held as inspired by some portion of the Christian church, and those which were never acknowledged as canonical. Among the first are some of the writings ascribed to the apostolical fathers. The First Epistle of Clement was read in the churches, is quoted in the same manner as Scripture by Irenæus, and is found in the Codex Alexandrinus. The Pastor of Hermas was also read in the churches, is mentioned as inspired by Irenæus, Clemens Alexandrinus, and Origen, and is found in the Codex Sinaiticus. Somewhat similar respect was paid to the Epistle of Polycarp and the Epistle of Barnabas. Besides these books there were different gospels in use in the early period of Christianity. The most famous of these was the Gospel according to the Hebrews. Some critics regard it as the earliest gospel of which we know anything. Its relation to our Gospels thus becomes a very important question, the discussion of which, however, must be reserved for the article on the GOSPELS (*q.v.*) The Ebionites used this gospel. It was written in Aramaic. It goes sometimes by the name of the Gospel of the Nazarenes, or by the Gospel according to the Apostles; and some think that it was also called the Gospel of Peter. This gospel no doubt underwent alterations; and Hilgenfeld, in his *Novum Testamentum extra Canonem Receptum*, gives the fragments of what he considers the earliest form of the Gospel according to the Hebrews, then those of the Gospel of the Ebionites, which he considers very late, and then those of the Gospel of Peter which he thinks occupied an intermediate place. We know very little more of the other gospels and apocryphal books than their names. Eusebius mentions the Acts of Peter, the Preaching of Peter, and the Revelation of Peter; the Acts of Paul, and the Doctrines of the Apostles. Origen mentions also the Gospel according to the Egyptians, the Gospel of Basilides, and the Gospel according to Thomas, and according to Matthias. Jerome, in addition to these, notices the Gospel according to Bartholomew, and the Gospel of Apelles. Marcion also used a special gospel for his sect, but whether it was the Gospel of Luke, entire or mutilated, is keenly debated. And the book of the Prophet Elxai was held in high estimation by some sects. All these works have perished, and criticism can only conjecture, from a few scattered hints and fragments, what was their nature. The other set of apocryphal books consists of works that have come down to us relating to Christ and his apostles, but which were never regarded as inspired by any sect. Some of these had a wide circulation in the Middle Ages, were translated into various languages, and, as might be expected, were subjected to all kinds of interpolations and alterations. Several of them refer to the infancy and boyhood of Jesus; such as the Protevangelium of James, the Gospel of Thomas, the Arabic Gospel of the Infancy; and some deal with his death, as the Gesta Pilati or the Gospel of Nicodemus, and the narrative of Joseph of Arimathea. There seems reason to believe that the first form of the Protevangelium of St James and the first form of the Gesta Pilati were written in the second century; but there can be no reasonable doubt that the forms in which we now have them belong to a much later date. There are also apocryphal Acts of Apostles and apocryphal Revelations of Apostles. These seem all to belong to a later date than the earliest of the apocryphal gospels. The fragments of the gospels used by the early church and the sects are given in Hilgenfeld's *Novum Testamentum extra Canonem Receptum* (Lipsiæ, 1866). The extant apocryphal Gospels, Acts, and Revelations have been edited in three separate volumes by Tischendorf, and have been translated by Mr Walker in vol. xvi. of Clark's *Ante-Nicene Christian Library*. These works contain references to the extensive literature on the subject. Special mention may be made of Michel Nicolas's work, *Etudes sur les Evangiles Apocryphes* (Paris, 1866), but almost all works on the Canon contain an account more or less full of the apocryphal books of the New Testament.

APOLDA, a town of Germany, in the grand-duchy of Saxe Weimar, situated near the river Ilm, 9 miles east of Weimar, with which it is connected by railway. Hosiery and cloth are the chief manufactures of the town, besides which it contains pin and button factories, and bell foundries. There are mineral springs in the neighbourhood. Population in 1871, 10,507.

APOLLINARIS SIDONIUS, CAIUS SOLLIUS, an eminent Christian writer and bishop, was born in Lyons about 430 A.D. Belonging to a noble family he was educated under the best masters, and particularly excelled in poetry and polite literature. He married Papianilla, the daughter of Avitus, who was consul, and afterwards emperor, by whom he had three children. But Majorianus, in the year 457, having deprived Avitus of the empire, and taken the city of Lyons, Apollinaris fell into the hands of the enemy. The reputation of his learning led Majorianus to treat him with the greatest respect; in return for which Apollinaris composed a panegyric in his honour, which was so highly applauded, that he had a statue erected to him at Rome, and was honoured with the title of *Count*. In 467 the Emperor Anthemius rewarded him for the panegyric which he had written in honour of him, by raising him to the post of governor of Rome, and afterwards to the dignity of a patrician and senator. But he soon quitted these secular employments for the service of the church; and, in 472, was chosen to succeed Eparchius in the bishopric of Clermont. On the capture of that city by the Goths in 480 he was obliged to retire, as he had taken an active part in its defence; but he was soon restored by Evaric, king of the Goths, and continued to govern the church as before. He died 482 or 484 A.D. His extant works are his *Panegyrics* on different emperors, and a collection of *Letters* and *Poems*, and their chief value consists in the light they shed on the political and literary history of the 5th century. The best edition is that by Sirmond, published in 1614, and republished in 1652.

APOLLINARIS, SULPICIUS, a learned grammarian of Carthage, lived in the 2d century, under the Antonines. He is the reputed author of the poetical arguments prefixed to the comedies of Terence. He had for his pupils Helvius Pertinax, who afterwards became emperor, and Aulus Gellius, who speaks of the acquirements and character of his master in terms of the highest praise.

APOLLO. The influence of the sun on nature in a country like Greece, either brightening the fields and cheering mankind, or scorching and destroying with a pestilence, or again dispelling the miasma collected from marshes by night, was taken by the Greeks to be under the control of a divine being, to whom they ascribed, on human analogy, a form and character in which were reflected their own sensations. That divine being they called Apollo, a name which applied to him in two ways, either as ἀπολλύων, from ἀπόλλυμι, "the destroyer," or as ἀπέλλων, from ἀπέλλω = ἀπείργω, the "repeller of ills." Apellon is both the Doric and the old Roman form of his name. Under the frequent title of Phœbus, he was hailed as god of the streaming light of the sun. Next to its daily course, which, however, was under the guidance of a special subordinate deity, Helios, the most obvious and invariable phenomenon of the sun was its withdrawal in winter and return in summer, and accordingly on this was based one of the principal features in the character of the god, which was also recognised in annual festivals in his honour, and made more explicit by the myth, in which after his birth, amid the splendid summer light of Delos, he is carried off in a car drawn by swans to the fabulous region of the Hyperboreans, where the sun was believed to tarry during the winter. The other class of solar phenomena, being variable in their occurrence, appeared to be directed by a precarious will, and from this was evolved for Apollo the double character of a god possessed of power over the sun, and a the same time guided in the exercise of it by the conduct of mankind. Hence the prominence of expiatory offerings in the worship of a god whom no act of wrong escaped. By his knowledge of what transpired on earth and in the councils of Olympus, he was prepared to be the god of oracles, which threw light on the future and banished the monsters begotten of terror at its obscurity. From observing the jubilant voice of nature greeting the sunshine, it was an easy step to regard Apollo as the god of music; while again the function of a god of medicine was peculiarly appropriate to a deity who, if he destroyed life, also saved it. In many ways the sun gladdened the herdsman and favoured his flock. Hence both Apollo and Helios (Sol) had sacred herds of cattle of their own, while the former when in exile on earth himself acted as a herdsman.

Apollo. From silver coin of Clazomenæ. Brit. Mus.

The honour of having been the birth-place of Apollo was claimed by many districts, but chiefly by Xanthus in Lycia, and the island of Delos, the latter being at last generally agreed upon. In Lycia his worship was of high antiquity, and its extent is vouched for by the identity of the name of that country with one of the favourite epithets of the god, Λυκεῖος, from root λυκ, as in λυκόφως, Lat. *luc-s = lux*. There also his mother Leto (Latona) appears to have been widely worshipped, and thither the solar hero Bellerophon goes to accomplish his labours, showing a community of religious belief between Lycia and Argolis, the home of Bellerophon, for which there is also other evidence. But when the myths concerning Apollo came to be shaped by the poets, his worship had acquired an independent standing in Delos, and had established for that island a claim to the honour of being his birth-place. The belief was that Leto, pursued by the jealous Hera (Juno), after long wandering, found shelter in Delos, and there bore to Zeus (Jupiter) a son, Apollo. To this it was added, after the time of Pindar, that Delos had before been a barren rock floating about in the sea, but had been for this purpose and for ever after fastened down by pillars, as also happened to the island of Rhodes, the centre of the worship of Helios. The labour of Latona lasted nine days and nine nights. Then she seized hold of a palm tree, and when the boy was born all the island was dazzled with a flood of golden light. Sacred swans flew in a circle round the island seven times. The day was the 7th of the month Thargelion (May). The 7th of every month was sacred to him. He was styled Ἑβδομαγενής, and otherwise the number seven played a part in his worship. His first step was to seize a bow and to announce his will to found an oracle. To this end his father Jupiter gave him, besides a lyre, and a mitra to bind his hair, a car drawn by swans, with which to proceed to Delphi. But the swans carried him off to their home among the Hyperboreans. Returning with the summer to Delphi, he slew with an arrow the Python, a monster dragon, which was then laying waste the district, established his oracle, and took the title of Pythios. Gæa (Terra) first, and next Themis had previously given oracles there. But this, though the current belief, is at variance with the Homeric Hymn to Apollo, which describes him as selecting Delphi for its site alone, and then relating how, after a temple was built, the difficulty of finding priests was overcome. Seeing a trading ship from Cnossus in Crete, under way for Pylus, the god threw himself on board in the form of a dolphin and guided it to Crissa, the harbour of Delphi, where, like the flash of a star, he resumed his divine form, appointed the traders his priesthood, and with his lyre led the first pæan there. Hence his title of Delphinios. But here a confusion has been effected; for, while in one sense Apollo Delphinios was god of the sunny voyages, in another sense he may have derived that epithet from having slain the dragon, the proper name of which was Delphine. Except on the latter theory, there seems to be no explanation of this, among other facts, that his sanctuary at Athens, the Delphinion, was a court for the trial of bloodshed. It may then be supposed that the Dorians from Crete, who had in early times established themselves on the coasts of the Peloponnesus and at Crissa, having an Apollo whose symbol was a dolphin, and finding at Delphi an Apollo styled Delphinios for another reason, combined the two in the new myth which is found in the Homeric Hymn. Besides at Delphi, which however retained the first place, Apollo gave oracles also at Colophon, and at Didymi near Miletus; in the latter place through the priestly family of the Branchidæ. To certain mortals he communicated the prophetic gift, as to Cassandra, the Cumæan sibyl, and the seer Epimenides. With his oracular power was associated his function as god of music (Citharœdus), and leader of the Muses (Musagetes), in which capacity he caused Marsyas to be flayed alive because he had boasted superior skill in playing the flute, or again, caused the ears of Midas to grow long because he had decided in favour of Pan, who contended that the flute was a better instrument than the lyre. But that which brought Apollo most closely home to the hearts of the people was his character of a destroying but yet an appeasable god. Pestilence and death by an unseen cause, or in the beauty of youth, were traced to him, and to prevent doubt as to his having a good reason in each case, there were the myths which told how, for example, he sent a pestilence on the Greeks before Troy, because Chryseis, the daughter of his priest, was retained in captivity by Agamemnon, or again, how with the aid of his sister Artemis (Diana) he slew the children of Niobe, because she had boasted of their beauty. A typical instance of his causing death undesignedly is that of his favourite, the beautiful young Hyacinthus, who was killed by the disc (a symbol of the sun) which Apollo had thrown in play. Besides accepting atonement in such cases, he was the god of the penitent generally, but especially of those, like Orestes, guilty of a crime which required years of expiation. For such he was himself the prototype, having been twice banished from Olympus, and compelled first to act for a period as herdsman to Admetus, the king of Pheræ, and next to assist Poseidon (Neptune) in building the walls of Troy for Laomedon. While thus the power of the sun god was recognised with varying feelings according to occasion, it was, on the other hand, always kept in view as an active principle in nature by the regular system of festivals. Of these the most remarkable was that called Carneia, which was annually held at Sparta in August, the whole population withdrawing from the town for several days, and living in tents to avoid the effect of intense heat. In July, also, the Spartans held a festival of nine days in his honour, called Hyacinthia, the burden of the ceremony being the transitoriness of life mingled with trust in its return. In Athens the festival of Thargelia was held in his honour in May, to celebrate the ripening of the fruits of the field; while in the Metageitnia, in August, he was regarded as the god of plenty, and as the source of neighbourly feeling. At Delphi, among a constant round of ceremonies, two festivals were conspicuous · at the beginning of winter, when the god was supposed to go away to the Hyperborean region, and at the beginning of summer, when he was believed to return; the latter event being hailed with every expression of delight in music and song. At Thebes was held every eighth year a peculiar ceremony, Daphnephoria, in honour of Apollo Ismenios, consisting of a procession in which was carried a branch of olive, hung with wreaths and representations of the sun, moon, planets, and stars, the number of wreaths being 365. This object was called the Kopo. In May the ancient national festival at Delos was celebrated. It remains to notice the very prevalent association of Apollo as sun-god with Artemis (Diana) as moon-goddess, the aspect of these two luminaries having readily suggested that their presiding deities were twins. But Apollo and Diana resembled each other also in many attributes of their character as well as in appearance. Just as he was god of the influence of the sun on nature, with a subordinate deity Helios (Sol) to guide the orb, so she personified the power of the moon, delegating its course to the goddess Selene (Luna). In Rome the worship of Apollo was not introduced until 320 B.C., in which year the city had been visited with a pestilence. The most frequent symbols of Apollo are the bow and the lyre; the tripod, suggesting his oracular power; the laurel, which was carried by penitents as well as worn by victors, and into which Daphne was changed for not yielding to his love; the palm, the wolf, the deer, and the raven. In the ripe period of art Apollo appears in a form which seeks to combine manhood and eternal youth. His long hair is usually tied, like that of his sister Diana, in a large knot above his forehead. As leader of the Muses, he wears long ample drapery girt at the waist, his tresses falling on his shoulders.

APOLLO BELVIDERE, a marble statue of Apollo, found towards the end of the 15th century near Antium (*Capo d'Anzo*), a favourite resort of Roman emperors. Julius II., while yet a cardinal, purchased it; and on becoming Pope allowed it to be placed, through Michael Angelo, in the Belvidere of the Vatican, whence it was taken by the French in 1797, but restored in 1815. The marble some believe to be Greek, though perhaps the best autherities call it Carrara. In any case the statue is not an original work, but a copy apparently from a very fine Greek statue of about the beginning of the 3rd century B.C., of which another copy has been identified in a bronze statuette now in St Petersburg, known as the Stroganoff Apollo. Lately also a marble head has been found at Rome, corresponding closely in measurement and in style, confirming what is suggested by the statue, viz., that the original was of bronze. From the bronze statuette it is found that the Apollo Belvidere held forward in his left hand, not a bow as was thought, but the *ægis*, in the attitude of spreading consternation among an enemy, as he did among the Trojans, and it is usual to adopt as the occasion for the production of this statue the invasion of the Gauls, whom, in 278 B.C., the god drove in alarm from his sanctuary at Delphi. The extraordinary praise bestowed on it by Winckelmann secured for this statue a fame from which the discovery of true Greek sculptures since then has gradually detracted, to this extent, that even its original cannot now be placed in the best period of Greek art.

APOLLODORUS, a celebrated painter of Athens who lived about 408 B.C. From the improvements he introduced into the art of mingling colours, and the use he made of shading, he obtained the surname, Σκιαγράφος.

APOLLODORUS, an Athenian grammarian, son of Asclepiades, and disciple of Aristarchus, lived about 140 B.C. His most famous production is his *Bibliotheca*, which treats of the gods and the heroic age; and though the extant work is possibly only an abridgment by another hand of the original, it is of great value in mythological inquiries. The best edition is that of Heyne, 2 vols. 8vo, published in 1803.

APOLLODORUS (60–130 A.D.), an architect, born at Damascus, a favourite of Trajan, for whom he constructed the stone bridge over the Danube (104 A.D.), which was esteemed the most magnificent of all the works of that emperor. He also planned a gymnasium, a college, public baths, the Odeum, and the Forum Trajanum, within the city of Rome; and the triumphal arches at Beneventum and Ancona. The Trajan column in the centre of the Forum is celebrated as being the first triumphal monument of the kind, and the model of many others in different cities, as Paris, London, St Petersburg, &c. On the elevation of Hadrian to the throne, Apollodorus was banished from Rome, and shortly afterwards, being charged with imaginary crimes, was put to death (Dion Cassius, lxix.)

APOLLONIA, the name, derived from the god Apollo, of several cities of antiquity. The most important are— 1. An Illyrian city on the right bank of the Aous, which owed its foundation to the Corinthians and Corcyreans. It soon became a place of commercial prosperity, was at a later period regarded as of military importance, and towards the close of the Roman republic acquired fame as a seat of literature and philosophy. It seems to have sunk with the rise of Aulon, and few remains of its ruins are to be found. 2. A Thracian city (afterwards Sozopolis, and now *Sizeboli*), colonised by the Milesians, and famous for its colossal statue of Apollo, which Lucullus removed to Rome. 3. The port of Cyrene (afterwards Sozusa, now *Marsa Sousah*), which at length outgrew the greatness of Cyrene itself, and has left ample evidence of its magnificence in the ruins of its public buildings. It was the birth-place of Eratosthenes, usually known as of Cyrene.

APOLLONIUS, surnamed Molo, a distinguished Greek rhetorician, the instructor of Cæsar and of Cicero. Born at Alabanda, he settled at Rhodes, and in the dictatorship of Sulla, was sent as ambassador from the Rhodians to Rome. He was the first Greek who addressed the senate without the aid of an interpreter. Cicero renewed his studies under him when he afterwards visited Rhodes on his return from Asia. The works of Apollonius have perished.—Another rhetorician of the same name, likewise a native of Alabanda, and an inhabitant of Rhodes, was surnamed The Effeminate (ὁ Μαλακός). Both are mentioned by Cicero with high respect.—Cicero, *Brutus*, 89, 90, 91; *De Inv.* i. 56, *De Orat.* i. 17, 28; Quintil. iii. 1, § 16, xii. 6, § 7, &c.

APOLLONIUS, surnamed Dyscolus (Δύσκολος), or The Crabbed, was a native of Alexandria, and lived in the reigns of Hadrian and Antoninus Pius. He was the first systematic writer on grammar, and is styled by Priscian "*Grammaticorum Princeps.*" Of his extant grammatical works the principal one is the treatise *On Syntax*, the best edition of which is that of Bekker, Berlin, 1817

APOLLONIUS, a Greek epic poet, surnamed Rhodius, from his long residence in Rhodes, though he is supposed to have been a native of Alexandria. He is known to us as the author of the *Argonautica*, a poem which he began while in youth, studying under the poet Callimachus. His master is supposed to have slighted the production of the youthful Apollonius, and their connection ended in the most violent enmity, though we are ignorant of the particulars of their quarrel. The disappointed youth retired to Rhodes, where he is conjectured to have polished and completed his work, supporting himself by the profession of rhetoric, and receiving from the Rhodians the freedom of their city. He was at length recalled to Alexandria to succeed Eratosthenes in the care of the great library about 194 B.C., in the reign of Ptolemy Euergetes, who had been educated by Aristarchus, and rivalled his predecessors in the munificent encouragement he gave to learning. The only extant work of Apollonius is his poem above mentioned, in four books, on the Argonautic expedition. Both Longinus and Quintilian have assigned to this work the mortifying character of mediocrity. It was first printed at Florence in 1496, with the ancient Greek Scholia, in a 4to volume, now exceedingly rare. An excellent edition was published by Brunck in 1780, and another by Beck, in 1797; but the best is that of Professor Schafer (Leipsic, 2 vols. 8vo, 1810–13). The poem was translated into English verse by Fawkes and Green in 1780; another translation in English verse, with critical notes, was published by W. Preston in 1803.

APOLLONIUS of Tralles and his brother Tauriscus were the sculptors of the famous Farnese Bull, a group representing Zethus and Amphion tying the revengeful Dirce to the tail of a wild bull. This work is now at Naples. There were several other sculptors named Apollonius.

APOLLONIUS, a grammarian of Alexandria, author of a Homeric Lexicon, Λέξεις Ὁμηρικαί, which was first published by Villoison, in two vols. fol., at Paris, in 1773.

APOLLONIUS of Perga (Pergæus), next to Archimedes the most illustrious of the ancient Greek geometricians, was born probably about 250 B.C., and died during the reign of Ptolemy Philopator (222–205 B.C.), flourishing thus about forty years later than Archimedes. He studied at Alexandria under the successors of Euclid, and is one of the brightest ornaments of that famous mathematical school.

But few of the mathematical works of Apollonius have escaped the ravages of time. Of the greater part we have merely the names and general description given by Pappus in his preface to book vii. of the *Mathematical Collections*. His treatise on the *Conic Sections* gained him the title of The Great Geometer, and is that by which his fame has been transmitted to modern times. It is not, indeed, to be for a moment supposed that Apollonius discovered all, or even the greater part, of the demonstrations which he gives, any more than that Euclid devised the propositions that go by his name. Pappus mentions several treatises on conics known to have existed previously—in particular the five books of Aristæus "The Ancient" (350 B.C.) on Solid Loci; and there can be little doubt that Apollonius availed himself of these, as well as of the discoveries of Conon, Euclid, Eudoxus, Menechmus, Nicoteles, Thrasidæus, and others, who had explored the way before him. At this distance of time we cannot distinguish the original from the borrowed propositions; but, though it is certain that he both added to and improved upon the existing theory of conics, the mere embodying in a complete and logical treatise of a number of miscellaneous theorems was in itself a work of great mathematical genius. Eutocius informs us that Apollonius was the first to show that all the three sections may be cut from the same cone, by varying the position of the intersecting plane, for previous authors had supposed the plane of section always perpendicular to the slant side of the cone,—an hypothesis which requires that the three sections be cut from cones of different species, namely, the parabola from a right-angled cone, the ellipse from one with an obtuse, and the hyperbola from one with an acute vertical angle. But Archimedes, as Ubaldus shows in his commentary on the *Æquiponderantes*, had been acquainted with this fact. Pappus ascribes to Apollonius the names by which the three sections are now distinguished; the term *Parabola*, however, occurs in the writings of Archimedes. Of the *Conicorum Libri Octo* of Apollonius, unfortunately only four have reached us directly through the original Greek. Three more have been preserved in an Arabic version, but the eighth has never been found. Though many attempts had been made to discover the last four books, they continued to be regarded as lost till 1658, when Borelli, the celebrated author of the treatise *De motu Animalium*, discovered in the Medici library at Florence an Arabic manuscript, entitled *Apollonii Pergæi Conicorum Libri Octo*. With the assistance of Abraham Ecchellensis he translated and published in 1661 the fifth, sixth, and seventh books; but the eighth, notwithstanding the title, was wanting. Some years previously Golius, Oriental professor at Leyden, had returned from the East with an Arabic version of the whole seven books, and had projected the publication of a translation; but it never appeared. A note appended to the MS. of Golius stated that the eighth book had never been translated into Arabic. It was long a favourite problem with geometers to attempt to restore the lost books of Apollonius, that is, to infer from the general nature of their contents, as described by Pappus, the propositions they had contained. Maurolycus, a Sicilian geometer of the 16th century, Viviani, the last favourite pupil of Galileo, Fermat, Halley, Simson, and a number of others, all attempted this with more or less success. Halley, guided by the descriptions of Pappus, and the assertion that his preliminary lemmas to the seventh book really belonged to the eighth, as well as by the statement of Apollonius himself that the eighth was a continuation of the seventh book, restored this book for the edition issued by the Oxford Press in 1710, the only edition of the Greek text that has as yet appeared. The last four books of the conics of Apollonius formed the chief part of the higher geometry of the ancients; and they present some elegant geometrical solutions of problems, which offer considerable difficulty even to the modern analytical method. For example, the fifth book treats of the greatest and least lines that can be drawn from given points to the peripheries of conics, and contains the chief properties of normals and radii of curvature.

The other treatises of Apollonius mentioned by Pappus are—1*st*, The Section of Ratio, or Proportional Sections; 2*d*, the Section of Space; 3*d*, the Determinate Section; 4*th*, the Tangencies; 5*th*, the Inclinations; 6*th*, the Plane Loci. Each of these was divided into two books, and, with the *Data* of Euclid and the *Porisms*, they formed the eight treatises which according to Pappus, constituted the body of the ancient analysis.

1*st*, *De Rationis Sectione* had for its subject the resolution of the following problem: Given two straight lines and a point in each to draw through a third given point a straight line cutting the two fixed lines, so that the parts intercepted between the given points in them and the points of intersection of this third line, may have a given ratio.

2*d*, *De Spatii Sectione* discussed the similar problem, which requires that the space contained by the three lines shall be equal to a given rectangle.

Dr Halley published in 1706 a restoration of these two treatises, founded on the indications of their contents given by Pappus. An Arabic version of the first had previously been found in the Bodleian library at Oxford by Dr Edward Bernard, who began a translation of it, but broke off on account of the extreme inaccuracy of the MS.

3*d*, *De Sectione Determinata* resolved the problem: In a given straight line to find a point, the rectangles or squares of whose distances from given points in the given straight line shall have a given ratio. Several restorations of the solution have been attempted, one by Snellius, another by Alex. Anderson of Aberdeen, in the supplement to his *Apollonius Redivivus* (Paris, 1612), but by far the most complete and elegant by Dr Simson of Glasgow.

4*th*, *De Tactionibus* embraced the following general problem: Given three things (points, straight lines, or circles) in position, to describe a circle passing through the given points, and touching the given straight lines or circles. The most difficult case, and the most interesting from its historical associations, is when the three given things are circles. This problem, though now regarded as elementary, was proposed by Vieta in the 16th century to Adrianus Romanus, who gave a very clumsy solution. Vieta thereupon proposed a simpler construction, and restored the whole treatise of Apollonius in a small work, which he entitled *Apollonius Gallus* (Paris, 1660.) Both Descartes and Newton have discussed this problem, though they failed to give it that simplicity of character which it has since been shown to possess. A very full and interesting historical account of the problem is given in the preface to a small work of Camerer, entitled *Apollonii Pergæi que supersunt, ac maxime Lemmata Pappi in hos Libros, cum Observationibus*, &c. (Gothæ, 1795, 8vo).

5*th*, *De Inclinationibus* had for its object to insert a given straight line tending towards a given point, between two given (straight or circular) lines. Restorations have been given by Marinus Ghetaldus, by Hugo de Omerique (*Geometrical Analysis*, Cadiz, 1698), and elegantly by Dr Horsley (1770).

6*th*, *De Locis Planis* is merely a collection of properties of the straight line and circle, and corresponds to the construction of equations of the first and second degrees. It has been successfully restored by Dr Simson.

The great estimation in which Apollonius was held by the ancients, and the great value attached to his productions, are manifest from the number and celebrity of the commentators who undertook to explain them. Among these we find the names of Pappus, the learned and unfortunate Hypatia, Serenus, Eutocius, Borelli, Halley, Barrow, and others. Various discoveries in other departments of mathematical science were also ascribed to him by the ancients. Pappus says that he made improvements on the modes of representing and multiplying large arithmetical numbers The invention of the method of projections has been attributed to him; and he has the honour of being the first to found astronomical observations on the principles of geometry.

The best editions of the works of Apollonius are the following:—1. *Apollonii Pergæi Conicorum libri quatuor, ex versione Frederici Commandini.* Bononiæ, 1566, fol. 2. *Apollonii Pergæi Conicorum libri v. vi. vii. Paraphraste Abalphato Asphanensi nunc primum editi: Additus in calce Archimedis Assumtorum Liber, ex Codicibus Arabicis Manuscr. Abrahamus Ecchellensis Latinos reddidit. J. Alfonsus Borellus curam in Geometricis Versioni contulit, et Notas uberiores in universum opus adjecit.* Florentiæ, 1661, fol. 3. *Apollonii Pergæi Conicorum libri octo, et Sereni Antissensis de Sectione Cylindri et Coni libri duo.* Oxoniæ, 1710, fol. (This is the splendid edition of Dr Halley.) 4. The edition of the first four books of the Conics given in 1675 by Barrow. 5. *Apollonii Pergæi de Sectione Rationis libri duo: Accedunt ejusdem de Sectione Spatii libri duo Restituti: Præmittitur,* &c. *Opera et Studio Edmundi Halley.* Oxoniæ, 1706, 4to.

See Bayle's *Dictionary*; Bossut, *Essai sur l'Hist. Gén. des Math.*, tome i.; Montucla, *Hist. des Math.*, tome i.; Vossius, *De Scient. Math.*; Simson's *Sectiones Conicæ*, preface; and Hutton's *Mathematical Dictionary*.

APOLLONIUS, surnamed TYANÆUS, a Pythagorean philosopher, born at Tyana, the capital of Cappadocia, shortly before the Christian era. According to his biographer Philostratus, he studied grammar and rhetoric at Tarsus under Euthydemus, but he soon left that gay and luxurious city for the quiet town of Ægæ in the vicinity, where he spent his time in the company of philosophers and priests within the temple of Æsculapius. Among these he met Euxenus, one of the followers of Pythagoras, and from him he learned with enthusiasm the doctrines of the Samian sage. While yet a mere youth he renounced all the ordinary pleasures of life. Abjuring the use of flesh and wine, he lived on the simple fruits of the soil, wore no clothing but linen and no sandals on his feet, suffered his hair to grow, and slept on the hard ground. He strictly observed the Pythagorean penance of five years' silence, suffering often the most painful trials of his patience without a murmur. Philostratus relates so many wonderful stories of his hero—how on one occasion, for instance, he awed an excited populace to silence by the mere waving of his hands, how he performed many miracles with a word, and how he knew all tongues without ever having learned them—that some have questioned the very existence of Apollonius; while others, admitting with reason the fact of some such ascetic having lived about this time, regard him as a compound of magician, impostor, and religious fanatic.

After spending some time in the cities of Cilicia and Pamphylia, Apollonius extended his travels into the East, and wandered on foot over Assyria, Persia, and India, conversing with Magi, Brahmins, Gymnosophists, and priests, visiting the temples, preaching a purer morality and religion than he found, and attracting wherever he went admiration and reverence. At Nineveh he met with Damis, who became his adoring disciple and the companion of his journeyings, and left those doubtful records of his life which Philostratus made use of, and probably improved upon. The account of his exploits during his wanderings in India reads like the tales of the Arabian Nights; and where Damis cannot vouch for having seen the prodigies he mentions, he unhesitatingly adduces in support of them the authority of his master. From his visit to the Hill of Sages (described in the third book), Apollonius returned an accomplished sage himself, able to foretell earthquakes and eclipses, to cure the plague, to summon spirits from the unseen world, and to restore the dead to life.

On his return from the East he had the greatest reverence paid him everywhere by Grecian priests and oracles. He visited Crete and Rome, where he astonished the magistrates by raising to life the dead body of a noble lady. Spain, Sicily, Egypt, Ethiopia, Greece, and Asia Minor became in time the scenes of his wanderings and his wonder-workings; and so distinguished had he become that even during his life he was raised almost to the rank of a divinity.

He is supposed to have died at Ephesus at a very great age, but his biographer finds it convenient to represent his end as involved in mystery, in order to heighten the reverence due to his hero. The words of the biographer are: "Here ends the history of Apollonius the Tyanæan, as written by Damis. Concerning the manner of his death, *if he did die*, the accounts are various." Like Pythagoras, his master, he left no indication of his age; and Philostratus could not ascertain whether he died at Ephesus, or *vanished* at Lindus, or in Crete.

After his death Apollonius was worshipped with divine honours for a period of four centuries. A temple was raised to him at Tyana, which obtained from the Romans the immunities of a sacred city. His statue was placed among those of the gods, and his name was invoked as a being possessed of superhuman powers. The defenders of paganism, at the period of its decline, placed the life and miracles of Apollonius in rivalry to those of Christ; and some moderns have not hesitated to make the same comparison. There is no reason to suppose, however, that Philostratus entertained any idea of this sort in composing his life of Apollonius. That biography was undertaken by order of Julia, wife of the Emperor Severus, more than a century after the death of the subject of it; and it is extraordinary that Apollonius, if so renowned and widely known in his day, found no place in history for 120 years after his decease. The preamble of Philostratus, in which he professes to set forth things with which men were before unacquainted, is in striking contrast with the commencement of the Gospel of Luke.

Apollonius is not to be looked upon as a shallow and vulgar impostor, though to influence men's minds he had recourse to artifices and pretensions unworthy of a true philosopher. With some of the spirit of a moral and religious reformer, he appears to have attempted, though vainly, to animate expiring paganism with a new and purer life. See PHILOSTRATUS.

APOLLOS, a Jew of Alexandria, who came to Ephesus during the absence of St Paul at Jerusalem (Acts xviii. 24). Apollos was a learned man (λογίος, in the authorised version translated *eloquent*), "mighty in the Scriptures," and preached "boldly" in the synagogue the doctrine of a Messiah, knowing as yet "only the baptism of John." Aquila and Priscilla having heard him, instructed him more fully in the doctrines of the gospel. Some time after this he went to Corinth, and was there very useful in convincing the Jews out of the Scriptures that Jesus was the Christ. Thus he watered what St Paul had planted in that city (1 Cor. iii. 6). The division in the church at Corinth, in which one of the parties called itself by his name (1 Cor. i. 12), was not prompted by him, and did not disturb the friendly relations that existed between him and St Paul. Apollos hearing that the apostle was at Ephesus, went to meet him, and declined to return to Corinth, though St Paul "greatly desired" him to do so (1 Cor. xvi. 12). St Jerome says that Apollos was so dissatisfied with the division at Corinth, that he retired into Crete with Zenas, a doctor of the law; and that the schism having been healed by St Paul's letter to the Corinthians, Apollos returned to the city, and became its bishop. Less probable traditions assign to him the bishopric of Duras, or of Iconium in Phrygia, or of Cæsarea.

APOLOGETICS is, properly speaking, that part of theology which vindicates the right of theology in general, and of Christian theology in particular, to exist as a science, and is occasioned by the presence of anti-theological and antichristian speculation. Apologetics is therefore the scientific representation of the grounds on which Christian theology, in so far as it is a part of human knowledge, rests and may be vindicated. So long as Christianity lies hid, as it were, in the mind of man or in the consciousness of the church, without assuming an external or objective form, so long as it remains only in the form of a force impelling men to action, so long as it is content to manifest itself on the active or practical side only, there is no great need of Apologetics; but whenever Christian dogmatics arise, whenever Christianity objectifies itself on its intellectual side, and begins to force its way into the circle of the sciences, its entrance is disputed, it has to face hostile criticism, and begins to form an apologetic.

Apologetics is therefore the logical antecedent but the historical consequent of dogmatics; it is the introduction to dogmatics, it prepares the way for it logically by justifying its claim to exist, but it actually comes after dogmatics in the history of the intellectual manifestation of Christianity, because, as a matter of fact, men do not feel called on to justify Christian theology until it actually exists in a dogmatic form. Thus, Apologetics may be compared to psychology, and in some respects is to dogmatics what psychology is to metaphysics. Just as psychology is the link between physics and metaphysics, just as in psychology the two spheres of impersonal and personal life touch each other, and the two sets of natural and spiritual laws are seen in conjoint action, so Apologetics lies between human and superhuman science, in it the two spheres of human life and revelation meet, and the various and different laws which regulate each adjust themselves to each other's varying action; and psychology, which is historically consequent to metaphysics, is logically its antecedent and introduction. The position of Apologetics necessarily gives it a somewhat changeable nature. All sciences change, but they do so according to an inward development of their own, and their change is so far orderly and progressive; but the course of Apologetics must always be more or less erratic, because it has to do with the varying relations of the two spheres of human life and revelation, and has to adjust itself afresh at each change in these relations. The special form, too, which Apologetics has for the most part assumed—a defence or vindication of Christianity—has made it more changeable. It has been compelled to change its front from time to time to meet the altered form of attack.

In one aspect the general science of Apologetics and the number of treatises upon the subject mark the imperfection of dogmatics and the neglect of its study; for with the advance of theology, general Apologetics tends to disappear, and in its stead comes an apologetic introduction, justifying each of the fundamental doctrines of dogmatics; or, in other words, with the advance of theology, Apologetics gives place to speculative theology, which shows the various relations in which each particular dogma stands to all other dogmas, whether theological or other.

Apologetics, as the justification and vindication of Christian theology, has to deal with two great questions; (1), Can man know God? and (2), Does man know God? Is a theology possible? and if so, is Christianity true and the theology which it gives, the true theology?

Under the first question are discussed all the various topics concerning man and his natural capacities for a knowledge of God and the things of God, the natural craving for a knowledge of the supernatural, the intimations more or less obscure of a higher than merely natural life.

Under this head comes every discussion concerning the capacities in man for the knowledge of God, and concerning the actual amount of knowledge which man has had of God apart from revelation The apologist endeavours to show from psychology, metaphysics, and other sources of knowledge capable of aiding him in his research, that man is a religious as well as an intelligent being, that theology on its formal side has a real basis in the human mind, and that whenever the objects of theological science are presented to the mind, they may be assimilated by these faculties. Many delicate questions arise here—the whole question of anthropomorphism, for example. It is argued that because our knowledge of God and of divine things must pass through and be assimilated by human faculties, it must necessarily be as much human as divine, and in this way the divine is more or less transformed into the human, and becomes anthropomorphic. The doctrine of the personality of God is often instanced as a notable example of anthropomorphism in theology. Apologetics vindicates theology from this charge by ascertaining from psychology whether the human factor tends to vitiate all human knowledge, and what is the precise influence of the formal element, or that element which the mind supplies, upon the material of human knowledge, and in this way tries to show that theology, while it is knowledge which passes through the mind of man, is not necessarily anthropomorphic.

But man has not merely capacity to know God and divine things, he actually does know something about these things; they have actually become objects or material of human knowledge. This brings us within the range of natural theology, which is just the sum of the knowledge which man, apart from revelation, has about God. Natural theology may be studied and its results presented in two different ways. Paley, Butler, and Chalmers, for example, have endeavoured, from an analysis of the human mind and character, to describe the kind and amount of knowledge which man has of the being and attributes of God, of the moral government of the world, of the immortality of the soul, and of the future state of reward and punishment. This method of inquiry is open to the objection, that it is very difficult to separate between what man has acquired by revelation and what he possesses without revelation, if the mind analysed be one already impregnated by Christianity. Hence it is well to supplement and correct the knowledge obtained in this way by an historical survey of what man has actually known and taught concerning God and divine things in the great natural religions which have existed, and still exist. Natural theology, in this sense of the word, is the result of a comparative history of religions, and contains a methodical summary of all the various religious ideas which have been evolved in the religious experience of mankind. The historical method is useful to correct the analytic, and the analytic gives order and method to the historical. This historical method is as yet in its infancy, but few historical sciences are engaging more attention than the new science of religions, and its growth cannot fail to have a considerable effect upon the future course of Apologetics. It looks upon all religions as more or less related to each other, and seeks to find the real course of the development of religious ideas, and natural theology becomes in this way the orderly statement of the various religious truths which each natural religion has contributed to the sum of the religious knowledge of the race; and every great religion is conceived to leave behind it a residuum which is its contribution to natural theology. But while Christian Apologetics thankfully acknowledges the contributions made by natural theology to our knowledge of God and His relations to us, it is always much more disposed to regard them as of indirect than of direct value. They are of more use in showing that man has capacities whereby he may arrive at a knowledge of theology, that he has aspirations which can only be satisfied by theology, than in furnishing actual and reliable information about God and His relations to us. They serve to prove that man is able to learn truths about God if the true materials of information were presented to him, or, in other words, in Apologetics natural theology has a *formal* rather than a *material* value.

2. *Does* man know God? Is the Christian theology *true?* Christianity is founded on certain presuppositions, can these be vindicated? The most important of these is the presupposition of the possibility and actual existence of a divine revelation, or a superhuman source of knowledge of God and His relations to us, and the most important task of Apologetics is to vindicate the possibility and existence of the Christian revelation. It is because it possesses this revelation that Christianity claims for itself a position altogether different from other religions, and hence the possibility and fact of a revelation have always been attacked by antichristian speculation. The precise point of attack has varied continually, but in the present day the chief objection to a revelation, in the Christian sense of the word, is based upon the fact, that an historical study of religions shows that every religion has professed to be founded upon a divine revelation, and claims for itself the same supernatural sanction which the Christian theologian declares to be the exclusive possession of Christianity. To this the apologist answers, that the fact that numberless false claims have been made is not a sufficient ground for summarily rejecting the claim of Christianity, which has to be judged upon its own merits, he then proceeds to point out, that just as Christianity professes to be different in kind, and not in degree only, from other religions, so the Christian revelation is one generically distinct, even in the external form which it assumes, from all other supposed revelations. While most pretended revelations claim to be the promulgation of divine truths, the Christian revelation is the manifestation of a divine life in the world, the intrusion into human history of a divine force, which, flowing on from generation to generation, at last condenses itself in the presence and person of the Lord Jesus Christ, the perfect revelation of God. It is sufficient to disprove the claims of any pretended revelation, to show that the truths it teaches might have been reached without any special and supernatural communication, but before the Christian revelation can be discredited, it must be shown that the divine life in the world, which reached its most perfect development in Jesus Christ, is not specifically different from the life of man,—that Jesus Christ was a mere man, not different in kind from other men. The great difference, then, between the Christian and other so-called revelations is, that it ends and is summed up in the person and work of Christ, and so is a consistent whole; while they do not end in a life like that of Christ, and lacking this to bind them together into a unity, are merely a more or less disjointed series of statements—not even the record of supernatural manifestation, still less that manifestation itself.

The first thing, therefore, that Apologetics has to do, in this its second and most important division, is to describe the character and meaning of revelation, discuss the possibility of the thing from all sides,—logical, metaphysical, and moral,—show that it can be known by man, and prove its necessity for the religious life of mankind.

The apologist must describe carefully the character and course of this divine life which has entered into history for the purpose of redemption, explaining it both on its objective side of manifestation and on its subjective side of inspiration. He has to show how it appears in miracle, and is apprehended by the mind specially fitted for this apprehension; and he points out that such a conception as that of the Christian revelation, such an idea as that of the continuous manifestation of God in the world, does not belong to any pagan religion or theology.

This manifestation of God, which is *miracle* in the proper sense of the word, and the special apprehension of it, which is *inspiration* in the more limited meaning, have happened, and have been recorded, and the apologist has therefore as much to do with the record of the revelation as with the revelation itself; and hence, after the preliminary investigations into the nature of revelation and its twin sides, manifestation and inspiration, comes an investigation of the sources from which we derive our knowledge of this revelation. The whole question of the Canon of Scripture must, therefore, be looked into and settled, the character, historical or other, the authenticity, and the credibility of the various books of the Old and New Testaments must be discussed, and whatever assistance in this task can be obtained from contemporary history must be taken advantage of. Connected with this inquiry, several difficult and delicate questions arise, about the relation between inspiration and perfect historical accuracy in every point, the questions of plenary and non-plenary inspiration, whether plenary inspiration requires perfect accuracy in minute details of history, whether it demands scientific accuracy of description, &c., none of which can be entered into here.

From the records of the revelation the apologist turns to the revelation itself. We have already distinguished the Christian from other pretended revelations, by saying that it is a revelation which has Christ, while other revelations have not Christ, and in our day the whole attack and defence have centred round the doctrine of our Lord Jesus Christ. The opponents of Christianity, feeling that the core of the system which they are attacking is the supernatural life of Christ, set themselves to attack that conception, and they do so by attempting to show, either that there was no such life as that of the Jesus Christ of the Gospels, or else that it was not supernatural—there was no such man as Jesus Christ, or if there was, He did not differ wholly from other men. The first mode of attack is that adopted by D. F. Strauss, and the second that of Ernest Renan and others. Strauss's position is somewhat of this kind: the historical and the supernatural are so inextricably mixed the one with the other that they cannot be separated, but the supernatural is on general grounds impossible, and therefore the historical is impossible also. He accordingly sets himself to show that the Gospels are not credible as history, and he resolves the Gospel life of Jesus of Nazareth into a poem, *the* poem of the Jewish nation and, indeed, of the human race. This is the basis of his celebrated mythical theory. Renan, on the other hand, cannot admit the thorough-going destructive criticism of Strauss. There must have been such a life as that of Jesus of Nazareth, although the account we have of it is a highly coloured picture. He admits the life, but denies the supernatural element in it, and explains it by saying that it was created round about the historical life by the enthusiasm of the early disciples; in short, he separates the historical from the supernatural, and while he admits the one he rejects the other. The apologist answers such attacks as these very much by pitting the one antagonist against the other. He asserts with Strauss that the historical and the supernatural are inseparably blended, and he takes from Renan the general idea, that, according to all laws of historical research, the Gospel narratives are truly historical. In this way he tries to show, epecially against Strauss, that there is no time, even if the Gospel narratives are brought down to the latest possible date, for the growth of the poem into which he resolves the life of Christ; and specially against Renan, he points out that if the historical be granted even only to the length to which Renan goes, it is so blended with the supernatural that the miraculous cannot be separated from it. This defence of the historical and supernatural character of the life of Christ, and of Christianity because it has the life of Christ as its centre and essence, widens into a general description of His position and character as these are shown in the Gospels. Apologetics tries to show that Jesus Christ is, as it were, the sum of all the previous revelation of God contained in the Old Testament. It traces the broadening down of revelation, in order to show how perfectly the life of Christ came as the conclusion and perfection of all that went before, and that it fulfilled both Jewish prophecy and pagan aspiration. It attempts to show that Jesus is not merely the actual and perfect fulfilment of every previous theophany, but that He is and must be the Perfect Revelation of God. It does this in various ways: by describing the character of Jesus, unique intellectually and unique morally; by describing the teaching of Jesus, and its marvellous similarity and yet dissimilarity with the doctrines of Jewish revelation and Gentile philosophy; by describing the actual work of Jesus, by showing that in Him miracle or manifestation and prophecy or inspiration came to their culmination; and by pointing to the mission of the Holy Ghost and the victorious spread of Christianity throughout the world. Such is a short outline of Apologetics and the field of investigation which it occupies: we shall now proceed to give a short summary of the history of the study.

The historical course of Apologetics may be divided into five great periods:—

The first period, extending from the beginning of the 2d century to the end of the 5th, may be subdivided into two: (1.) From the beginning of the 2d to the beginning of the 3d century; and, (2.) From the beginning of the 3d to the end of the 5th. The first of these is marked by the writings of Justin Martyr, Athenagoras, Tertullian, and Minucius Felix. The two Apologies of Justin were directed, the one against the Jews, and the other against the pagans. In both he follows the same method of justifying the Christian religion from the charges which were then commonly brought against it, and then attacking his opponents severely. All the apologists of this age follow the same course, and we see from their writings that the common attacks upon Christianity were charges of atheism, immorality practised at their Agapæ, the Thyestæan banquets, and the like. The second of these periods is marked by the writings of Origen, Arnobius, Lactantius, Eusebius, Cyril of Alexandria, Augustine. These names show the course that Apologetics was taking. It had raised itself far above the position of a mere defence against vulgar prejudice and polished sarcasm; and Origen, when he opposed Celsus, was giving a philosophical defence against a philosophical attack upon the principles which lay at the basis of Christianity (*cf.* Pressensé's *Hist. de l'Eglise*, 2^{me} série, ii. pp. 104–142). With Arnobius begins the study of Christian evidences; and he tries to show that Christianity is not merely probable, but certainly true; while Lactantius proceeds upon the idea that, if Christianity be only clearly understood, it must be accepted, that its best defence is a clear statement of the principles on which it rests. Eusebius, on the other hand, is the first of the learned apologists, and proves the truth of Christianity by an elaborate comparison between it and all that was best in the various systems which went before it, and so far prepared the way for it. Cyril opposes Julian as Origen had opposed Celsus. Julian had directed his attack against the claims of Christianity to universal dominion; he admitted that it was one form, but denied that it was the only form of truth, and Cyril's defence is interesting, inasmuch as it is the first answer of the Christian apologist to the objections of the pure Theist. Augustine's great work, the *De Civitate Dei*, is apologetic in so far as it endeavours to show that Christianity and the church are the only ark of safety in presence of the dissolution of the empire and human society which then seemed imminent. In this second division of the first period, Christianity has become triumphant, and the duty of Apologetics has not been to defend it from the coarse attacks of passion and prejudice, but to give a philosophical answer to philosophical objections, and then to show how Christianity adapts itself to the intellectual, moral, and political requirements of men and nations.

The second period dates from the 6th to the middle of the 15th century. It is that period in the history of theology in which the church attempted to rule thoroughly the intellectual life of mankind; when the *ecclesia salvans* had become an *ecclesia docens*, and the *ecclesiæ patres* had given place to the *ecclesiæ scholastici*. It embraces the growth, life, and decline of scholasticism. In this period there are no direct attacks upon Christianity, and so no direct defences of it; but still Apologetics, although for the most part absorbed into the sum of Christian doctrine, and recognisable only in the attempt to assimilate philosophy and theology, is to some extent visible in the jealous defence of particular doctrines against the attacks of Nominalism, and reveals itself more prominently in the attacks made by Christian theologians upon the Jewish and the Mahometan religions. Such works as Abelard's *Dialogus inter Philosophum Judæum et Christianum*, and Thomas of Aquin's *De Veritate Catholicæ Fidei contra Gentiles*, are the best examples of the Apologetics of this second period.

The third period extends from the middle of the 15th to the middle of the 17th century. This was the age of the Renaissance and of the Reformation, an age of inquiry, doubt, and change. Along with the Reformation, keeping with it as long as it was merely destructive, and abandoning it as soon as it became constructive, was a spirit or tendency, best described by the term Humanism. The Humanists were men who were thoroughly imbued with the spirit of the old classical poets of Greece and Rome, and had imbibed many of the old pagan ideas with reference to Christianity. Humanism, which was at first learning revived, contained within it two tendencies which afterwards showed themselves hostile to Christianity: the first was embodied in literary criticism, and mainly displayed the antagonism between literature and dogma, while the other took the form of a pantheist philosophy founded on the divinity of Nature. The most notable of the apologetical works of this period are those of Marcilius Ficinus (*De Religione Christiana*), Eugubinus Steuchus (*De Perenni Philosophia*, from which Bishop Berkeley has borrowed largely in his *Siris*), and Johannes Ludovicus Vives (*De Veritate Religionis Christianæ*).

The fourth period extends from the middle of the 17th to the end of the 18th century. During this period, antichristian speculation assumes distinct forms, and Apologetics undergoes corresponding changes. The period has three divisions, which are to some extent successive, but are best distinguished by the form of unbelief then prevalent—the English deism, the French scepticism, and the German rationalism. The English deism, which began with Lord Herbert of Cherbury and Hobbes, and ended with Hume, called forth an innumerable number of replies from Christian theologians, and the special nature of the attack then made upon Christianity still gives their special form to English works upon Apologetics. The general tone of English Deists was that there was no warrant for the mysteries in Christianity, for its superior morality, for its historical position and influence, and so English Apologetics has been mainly concerned with the doctrine of the *evidences* of Christianity; and the general line of argument commonly taken has been, that there is as much evidence for Christianity as for some ordinary set of opinions generally admitted. Thus Bishop Berkeley's *Alciphron, or the Minute Philosopher*, among other things, aims at establishing the existence of God by showing that the evidence is as strong as the evidence for the existence of our fellow-men; Locke's *Reasonableness of Christianity* shows that the Christian theology attacked is in all points able to be satisfactorily explained in accordance with human reason, if the same methods of investigation and adjustment be allowed, which are usually permitted when testing the reasonableness of any common statement or opinion; and in the *Analogy* of Bishop Butler the whole argument rests upon the basis:—the Deists make certain statements about religion; if these be true they contain as many difficulties as are to be found in Christianity, and difficulties of the same kind, therefore Christianity is as reasonable, at least, as deism or any system of mere natural theology. In the French scepticism, the principal charge made against Christianity was that it rested on imposture and was maintained by trickery. An attack of this kind is answered, not so much by special defence, as by a silent appeal to historical testimony and to the character of man, and it is not to be wondered at if the French Church has not produced any very valuable apologetic writings defending Christianity from the special attacks of this school. The German rationalism began with Lessing's publication of the *Wolfenbüttel Fragments*, (extracts from a work by Reimarus, a schoolmaster at Hamburg), and ended with Kant. In its earlier form it was little else than an importation of the ideas of the English Deists, but latterly it assumed a special form by upholding the authority of the *individual* reason. The replies to the ordinary arguments of the English Deists were very numerons (*cf.* Lechler's *Geschichte des Engl. Deismus*), but do not deserve further notice. The authority of the individual reason may be vindicated, either in the province of criticism or in that of dogma; the one effort gave rise to the critical rationalism of Eichhorn and Paulus, and the other to the dogmatic rationalism of Wegscheider. The critical rationalism of Eichhorn and his school has been gradually answered by the advance of criticism itself, which shows a progressive tendency towards higher and more spiritual ideas, if not to a recognition of the inspired authority of Scripture. The dogmatic rationalism of Wegscheider has fallen before the new impulse given to dogmatic theology by Schleiermacher and Neander.

At the present time Apologetics seems to be in a transition state. Since the time of Kant the historical method of investigation has become all powerful in almost every department of human knowledge, and at the present the chief attacks made upon the supernatural and unique character of the Christian religion and theology are based upon the comparative science of religions. It is held that the Christian religion is the highest and most perfect development to which the religious spirit of man has yet reached, but that it simply differs in degree of development from any other religion. It is said that the Christian theology contains, like all other theologies, a great many elements of truth, but that it is simply a natural religion like any other. This mode of attack has not yet been thoroughly faced by Christian apologists, but it must be the work of the Apologetics of the future to vindicate the supernatural character of Christianity by arguments which are based upon historical investigation and comparison of the different religions of mankind. For the general outline of Apologetics see *Hagenbach's Encyclopaedie*, and Heubner's article on "Apologetik" in Ersch and Gruber's *Allg. Encycl.* For natural theology *cf.* Paley's *Natural Theology*, Chalmers's *Natural Theology*, Bishop Butler's *Analogy*, and Hegel's *Philosophie der Religion.* The *Bampton Lectures* discuss many of the particular problems of Apologetics, and A. S. Farrar's *Critical History of Free Thought* (the *Bampton Lectures* for 1862) gives a very good history of Apologetics. (T. M. L.)

APOLOGUE. This word was originally, in Greek and Latin (ἀπόλογος, *apologus*), employed loosely for any kind of story, but has now become synonymous with *moral fable.* See FABLE.

APOPHTHEGM (ἀπόφθεγμα, from φθέγγομαι, to speak), a short, sententious, instructive utterance, as "Knowledge is power," "True greatness always wills." Of such sayings Plutarch made a famous collection in his *Apophthegmata Laconica*, and the biblical book of Proverbs abounds with examples. Every apophthegm is a possible proverb; to pass into a proverb it requires age and currency.

APOPLEXY (ἀπό, πλήσσω, to strike down, to stun), a term in medicine which, though now also employed with other significations, is commonly understood to apply to a fit of sudden insensibility occurring in connection with some diseased condition of the brain.

Apoplectic attacks vary both as regards their intensity and their attendant phenomena, but well-marked cases present the following symptoms: The person attacked becomes, more or less suddenly, deprived of consciousness and all power of voluntary motion. He lies as if in a deep sleep, with a flushed face, a slow pulse, stertorous breathing, accompanied with puffing of the cheeks during expiration, and with the pupils of the eyes insensible to light, and contracted or unequal. This state in many respects resembles the coma of narcotic poisoning, and is unfortunately too often mistaken by unskilled persons for alcoholic intoxication. The symptoms and history of the case, however, are usually sufficient to enable a medical man to form a correct diagnosis. In this condition of insensibility death may occur within a few hours, or there may be a gradual return to consciousness, in which case it is frequently observed that some trace of the attack remains in the form of paralysis of one side of the body, while occasionally there may also be noticed some impairment of the mental powers, pointing to damage done to the brain. (See PARALYSIS.)

Although thus generally sudden in its onset, it is seldom that an attack of apoplexy occurs without some previous warning. Persistent headache of a dull throbbing character, a sense of fulness in the head, vomiting, giddiness, noises in the ears, slight confusion of mind, and numbness of a limb or of one side of the body, are among the more important premonitory symptoms; and these may exist for a variable length of time before the fit comes on. . Such symptoms, more particularly the association of them, when occurring in a person at or beyond middle life are to be regarded with anxiety, as indicating danger of an apoplectic seizure. Various morbid conditions of the brain are capable of giving rise to fits of apoplexy. Hence different forms of apoplexy have been described by medical writers, such as the *congestive*, where the cause appeared to lie in an engorgement of the blood-vessels of the brain and its membranes; and the *serous*, where sudden effusion of fluid into the ventricles or substance of the brain seemed to have brought on a fit. But by far the most frequent and important occasion of apoplexy is hæmorrhage into the brain by the rupture of blood-vessels. Indeed, by many modern writers the term apoplexy is applied only to cases of cerebral hæmorrhage. The blood-vessels of the brain, like those in other parts of the body, are liable to undergo degenerative changes after middle life. These changes affect the minute capillaries, as well as the larger vessels, rendering their texture fragile, and at the same time impairing their function in carrying on the healthy nutrition of the brain. Hence, in the immediate vicinity of the diseased blood-vessels, the substance of the brain itself undergoes degeneration, and becomes softened. The capillary vessels having thus lost the natural support of the surrounding tissues, and being themselves weakened by disease affecting their walls, are liable to give way, and blood escapes into the brain. The hæmorrhage may be slight in amount and in parts of the brain where its presence gives rise to little disturbance; but where a large blood-vessel has ruptured, and more especially where the blood has been extravasated in or around the important structures at the base of the brain, the result is a fit of apoplexy as above described, and death not unfrequently follows within a short period. In favourable cases where a certain measure of recovery takes place, the effused blood undergoes gradual absorption, or becomes enveloped in a sort of capsule formed by the surrounding brain substance, and ceases to cause further disturbance. But even in such cases some degree of paralysis remains at least for a time. Moreover, the nutrition of the brain is so impaired as to render probable a recurrence of the hæmorrhage, and thus the danger to life, as is well known, increases with each successive attack.

From what has been above stated, it will be observed that apoplexy is to be regarded as a disease of advanced life. Hippocrates states that it is of most frequent occurrence between the ages of forty and sixty, and all medical experience confirms the truth of this observation. Nevertheless it may occur at any period of life, and cases are not wanting of true apoplexy in very young children. It is said to be more common in men than in women, but this is denied by many observers, and appears at least doubtful. What has from early times been described as the apoplectic habit of body, consisting in a stout build, a short neck, and florid complexion, is now generally discredited, it being admitted that apoplexy occurs about as frequently in thin and spare persons who present no such peculiarity of conformation. A hereditary tendency is acknowledged as one of the predisposing causes of apoplexy, as are also diseases of the heart and kidneys. With respect to the exciting causes of a fit of apoplexy, it may be stated generally, that whatever tends directly or indirectly to increase the tension within the cerebral blood-vessels may bring on an attack. Hence, such causes as immoderate eating or drinking, severe exertion of body or mind, violent emotions, much stooping, overheated rooms, exposure of the head to the sun, sudden shocks to the body, and the sudden suppression of evacuations, such as the menstrual discharge, may precipitate the fit.

A knowledge of these facts is of the utmost importance in the treatment of apoplexy, as obviously much can be done in the way of warding off fits where they appear to threaten, and of preventing a recurrence in cases where there have been previous attacks. With respect, further, to the treatment of apoplexy, it must be admitted that little can be done during the state of unconsciousness. The practice of blood-letting, once so common in this disease, is now almost entirely abandoned, although there are physicians who still recommend its employment, especially where the attack occurs in stout, plethoric persons. Where death appears to threaten from failure of the heart's action, warm applications to the surface of the body, and, should there exist any power of swallowing, the cautious administration of stimulants, are to be recommended. The case must be anxiously watched, and symptoms treated as they arise. When consciousness returns, the utmost care and quietness are to be observed to prevent the occurrence of inflammatory action, so apt to be developed, as a result of hæmorrhage into the brain.

The term *Apoplexy* is also applied in modern medical nomenclature to an extravasation of blood within the substance of any organ in the body, as for instance, *pulmonary apoplexy*, where blood has been effused into the tissues of the lung. This use of the word, however, is altogether objectionable. (J. O. A.)

APOSTASY (ἀπόστασις), denoting in classic Greek (Herodotus, Thucydides) a defection or revolt from a military commander, is generally employed to describe a complete renunciation of the Christian faith. In the first centuries of the Christian era, apostasy was most commonly induced by persecution, and was indicated by some outward act, such as offering incense to a heathen deity or blaspheming the name of Christ. The Emperor Julian, who is known in history as The Apostate, abandoned Christianity for paganism soon after assuming the purple, though it is questionable whether he had ever really embraced the Christian faith. In the Roman Catholic Church the word apostasy is also applied to the renunciation of monastic vows (*apostasis a monachatu*), and to the abandonment of the clerical profession for the life of the world (*apostasis a clericatu*). Of the latter class a celebrated instance was Talleyrand.

APOSTLE (Greek ἀπόστολος, one who is sent forth) is in the New Testament, and in Christian literature, a technical term—apostle of Jesus Christ. It appears from Mat. x., Mark vi., that the name was originally applied to the twelve disciples in reference to the special mission to preach and work miracles in Israel, on which our Lord sent them forth during His ministry on earth. Luke alone of the evangelists uses the word in a technical sense out of connection with this mission. After the resurrection the eleven, who again become twelve by the election of Matthias in the room of Judas, are regularly designated apostles. The precise prerogative of the apostolate is not defined. The apostles themselves feel that their distinguishing qualification is their personal fellowship with Jesus through all his ministry, their main office to witness to the resurrection (Acts i.) They do not act hierarchically (Acts xv.), and decline to be withdrawn by administrative cares from the ministry of the word and prayer (Acts vi.) Their central and unique position is, in truth, too universally allowed to call for precise definition. Nevertheless, the question, What is an apostle? soon became a burning one in the church. How far a lax use of the name extended it in a lower sense to others than the twelve is a question of little importance (Acts xiv. 4, 14; Rom. xvi. 7?); but when Paul claims to be an apostle, and especially the apostle of the Gentiles, his claim is to preach the gospel with the authority of one who is equal to the twelve, and responsible only to Christ. He is not an apostle (sent) from man or through man, he received his gospel not from man, but by revelation of Jesus Christ, whom he has seen as well as the twelve, and his apostleship is confirmed by miracles, and sealed by his success in founding churches (Gal. i.; 1 Cor. ix. 1, *ff.*, xv. 8, *ff.*; 2 Cor. xii. 12). The last mark is acknowledged by the twelve as decisive (Gal. ii.) Nevertheless, Paul's Judaising opponents continue to deny his apostolic authority (2 Cor.) The exact relation of parties which this controversy presupposes is a leading subject of debate in recent criticism. Here we have only to observe that the notion of apostleship now appears as that of evangelical authority derived direct from Christ and irresponsible to man. This authority is not properly administrative, though it is sometimes brought to bear on administrative questions. The apostleship is not a church office, but a *charisma*, similar to prophecy, but superior (1 Cor. xii. 28), and having its fit exercise in the founding of churches by direct testimony to Christ. Thus, the church is said to be built on the foundation of the apostles and prophets (Eph. ii. 20), not because they are the basis of the hierarchy, but because their activity lay at the root of the growth of the Christian society.

Very early, however, the notion that the apostleship is essentially an hierarchical office found entrance in the church. Irenæus and Tertullian regard the episcopate as a continuation of the apostolic functions, especially connecting this position with the idea of an authoritative tradition of apostolic doctrine. This view is further developed by Cyprian, and so becomes the foundation of the episcopal system of the Catholic Church, which regards all church power, especially disciplinary power, as entrusted by Christ to the apostles, from whom the bishops derive their authority by apostolic succession. This notion of the apostleship is based on an uncritical interpretation of Mat. xvi. 18, *f.*; John xx. 21, *ff.* The later Papal system goes still farther, so that Bellarmine and others teach that Peter alone was ordained bishop by our Lord, and all the other apostles by Peter.

Of the history of the apostles we have almost no authentic knowledge beyond what is stated in the New Testament. The names of the twelve are given in Mat. x., Mark iii., Luke vi., Acts i. With regard to these lists it is to be observed that the Lebbeus of Matthew is identical with the Thaddeus of Mark, and that both these titles must probably be viewed as surnames of the Judas whom Luke calls either son or brother of James (Ἰούδας Ἰακώβου). Bartholomew, too, is probably a patronymic of John's Nathanael. The history of the Acts tells little about any of the apostles except Peter and Paul; and precisely with regard to these names the statements of the book have been made subject of critical controversy. (See ACTS OF APOSTLES.) The later history of Peter has an artificial interest from the importance attached by the Roman Church to his episcopate at Rome, and the history of John is involved with the question of the genuineness of the Johannine writings. Pretty early tradition associates Philip with Phrygia, Thomas with Parthia, Andrew with Scythia, Bartholomew with India. Later traditions make the apostles divide the various countries between them by lot, and assert (against earlier tradition) that all except John were martyrs. The form ultimately assumed by the legendary history of the apostles may be seen in the Latin work which bears the name of Abdias, in Fabricii *Codex Apocryphus N. T.* (W. R. S.)

APOSTLES' CREED, one of the earliest and most generally accepted symbols of the Christian faith, so called from the fact that its authorship was attributed to the twelve apostles. See CREEDS.

APOSTOLIC or APOSTOLICAL, a name assumed at different times by various churches and sects on the ground of some special connection with the apostles. It was applied in the first centuries of the Christian era to certain churches that claimed to be founded by individual apostles and especially to Rome, Alexandria, Antioch, and Jerusalem. The title was also borne by the bishops of these churches as the successors of the apostles.

APOSTOLIC CANONS. These are rules to regulate Christian life and the discipline and government of the Christian church, which, it is supposed, have come down to us from the apostles. Several collections of rules claiming apostolic origin and authority have descended to us, and of these the two most important are the canons of the Apostolic Synod of Antioch and the collection now described, which bears the title *Canones qui dicuntur Apostolorum* (Κάνονες τῶν ἁγίων καὶ πανσέπτων Ἀποστόλων). The Apostolic Canons consist of a series of eighty-five rules, of which the first fifty are held to be the most important. These rules contain a tolerably complete directory for the guidance of the clergy in their daily life and usual round of duties. It is somewhat remarkable that the life of the ordinary layman is for the most part left unnoticed; four Canons only deal with the laity, the rest of them speak of the clerical life and that alone. The authority of these Canons varies in the Eastern and in the Western Church. The Eastern Church, following the guidance of John of Damascus, has received as authoritative the whole eighty-five, and makes them of equal authority with the Epistles of St Paul, *i.e.*, acknowledges that they possess plenary authority. The Western Church has always hesitated to receive more than the first fifty, and has received them more on the recommendations of such distinguished popes as John II., Stephen III., and Urban II., than because of their own intrinsic value; and it was only when they were incorporated in the decretals that they obtained a real authority.

According to some authors, they are first quoted in the Acts of the Synod of Constantinople, in 394 A.D., and in those of the Synods of Ephesus and Chalcedon, in 431 and 451 A.D. Some have said that they are mentioned in the *Decretum de libris recipiendis*, issued by Pope Gelasius (492–496 A.D.), while others have pointed out that the name occurs in those MSS. only which have the decree of Hormisdas (514–523). Perhaps the soundest decision is, that the collection is not mentioned in history until about the end of the 5th century; it is undoubted that it was in existence before the beginning of the 6th, for the Latin translation of the first fifty Canons dates from the year 500 A.D.

A great deal of criticism has been expended upon this collection of ecclesiastical rules. It was once commonly received that the Apostolic Canons were the authoritative decisions upon church life and discipline enacted by the first council of Jerusalem, whose proceedings are recorded in the Acts of the Apostles. Since the 16th century juster views have prevailed. The Canons themselves contain statements which are almost identical with many passages in Holy Scripture, and with many of the decisions of the earlier synods and councils, more especially those of Antioch, Nicæa, and Laodicea; it is also evident that much that they include is but the description of the tradition and practice of the church then existing. The following questions then arise:—(1.) Are the passages which resemble what we find in Scripture taken therefrom, or from contemporary independent oral tradition? and, (2.) Have the rules, which are almost literally identical with the decisions of the earlier councils suggested and formed the basis of these decisions, or are they themselves suggested by the decisions of the councils? When we bear in mind the fact that the historical existence of the Holy Scriptures and of the councils is well assured, and that we have no trustworthy evidence of the existence of this collection until the end of the 5th century, the conclusion forces itself upon us that the Apostolic Canons must be based upon the Acts of the earlier councils, not these upon the Canons. Critics have differed about the precise date of the compilation. The Magdeburg Centuriators think that it was some time in the 3d century; while Dalleus is of opinion that it was not until the middle of the 5th century; others place it between these dates. Perhaps the best conclusion we can come to is that the so-called Apostolic Canons are a compilation of practical rules for the guidance of the clergy made from holy Scripture, the decisions of the earlier councils, and existing ecclesiastical usage, by an unknown ecclesiastic belonging to the Syrian Church, who lived in the 4th or 5th century.

See Dalleus, *De Pseudepigraphis Apostolorum;* Franciscus Turrianus, *Pro Canonibus Apostolorum*, who asserts their apostolic origin; Bickrell, *Geschichte des Kirchenrechts.* (T. M. L.)

APOSTOLIC CONSTITUTIONS are a collection of eight books of directions and prescriptions on ecclesiastical and theological matters, for which apostolic origin and authority have frequently been claimed. It is probable that the first six books form the earliest part of the whole, and it is certain that they were known and quoted as a separate treatise, under the title *τὰ διδασκαλία τῶν Αποστόλων;* the seventh book was also separately known, and in many parts bears a curious resemblance to the Epistle of St Barnabas; the eighth is also an independent work, and is more legislative than the others. Historians have differed as to the first mention of the collection. Some, without much warrant, think that the work is mentioned by Eusebius and Athanasius, under the title *διδαχή* or *διδαχαὶ τῶν Ἀποστόλων;* while others, with more justice, think that it is not alluded to by any well-known writer until Epiphanius (d. 402), quotes it under the name *διάταξις τῶν Ἀποστόλων διδασκαλία.* It was well known in the 6th and 7th centuries. The book as a whole has never been received as an authority in the church, and its influence has been greater in the East than in the West. The principal defenders of its apostolic origin and authority have been such English Episcopalian writers as Stapleton, Whiston, and Pearson.

See Whiston, *Primitive Christianity Revived*, 1711; Baur, *Ueber der Ursprung des Episcopats in der Christlichen Kirche.* (T. M. L.)

APOSTOLIC FATHERS. The apostolic fathers is a name given to certain writers in the earliest period of Christianity, who were believed to have been the disciples of the apostles, and to have had intercourse with them. Those generally included under the title are Clemens Romanus, Ignatius, Polycarp, Barnabas, and Hermas. Sometimes the name is extended to Papias of Hierapolis and the writer of the Epistle to Diognetus. A critical examination of the writings attributed to these men, and a critical sifting of the traditions which we have in relation to their history, bring out the circumstance that the name is unsuitable. Clemens Romanus, Barnabas, and Hermas were supposed to be persons mentioned in the New Testament; but criticism proves conclusively that this is a mistake in regard to Barnabas and Hermas, and possibly also in regard to Clemens. Polycarp, in all probability, and according to the best testimony, had intercourse with apostles, but it was in his early youth; and his Letter belongs to a period considerably later than that of the apostles. The Epistles of Ignatius, as well as the personal history of that martyr, are involved in great obscurity, and critics differ widely in regard to both. At the same time, the writings assigned by most critics to these men with some degree of certainty belong to a very early age of Christianity. They are among the earliest utterances of the Christian faith which have come down to us. All of them are of the nature of occasional productions, with perhaps the exception of the Pastor of Hermas. All of them breathe a spirit of deep piety. There is no attempt to formulate the truths of Christianity. There are very few references to the books of the New Testament, and very few quotations from them. All of them are written in Greek.

Clemens Romanus.—According to the statement of Irenæus, Clemens was the third bishop of the Roman Church; this seems to have been the tradition among the Greek writers. Tertullian, on the other hand, seems to have believed that he was the first bishop, and that he had been ordained by St Peter. Origen regarded him as the Clemens mentioned in the Epistle to the Philippians, and Clemens Alexandrinus often calls him an apostle. Nothing is known of his death. Very late fictions represented him as a martyr. Eusebius gives as the date of his episcopate from 93 to 101 A.D. The only writing which can in any satisfactory manner be ascribed to Clemens Romanus is an epistle from the Roman Church to the Corinthian. Quarrels had arisen in the Corinthian Church, most probably in the reign of Domitian, as to some of the office-bearers of the church. And the Roman Church sent a letter to the Corinthian Church urging it to pursue a peaceful course, to shun envy and jealousy, and to do all things in order. The writing of this letter is ascribed to Clemens by Dionysius, bishop of the Corinthian Church, in a letter to Soter, bishop of the Roman Church (166–174 A.D.), and all subsequent testimony is in favour of this authorship. The letter was found at the end of the Codex Alexandrinus. Its position there is in harmony with the circumstance noted by several of the ancients, that it was read in the churches on the Sunday. Clemens Alexandrinus also frequently quotes it as the work of the "Apostle Clemens," and the mode of quotation is such as to lead one to believe that he regarded it as Scripture, though some have maintained that he did not regard it as canonical. The genuineness of the epistle has been generally acknowledged. There is strong external testimony for it, and the internal evidence is at least not against it. But as Dionysius of Corinth (166 A.D.) is the first to mention Clemens as the author, there is a considerable interval between the date usually assigned to the epistle and the time of Dionysius, during which no one testifies to the epistle. Accordingly some critics have refused to recognise Clemens as the author, and they put the letter well on into the 2d century. The date usually assigned to the letter is 96 or 97 A.D. Some critics have assigned it to the year 68 A.D., but the arguments are not satisfactory. Some writers have taken exception to a few chapters in the letter which they regard as interpolations, but their opinions have not been generally adopted. The letter is defective. A whole leaf of the MS. is supposed to be wanting. The best edition of the epistle is by Professor Lightfoot (London and Cambridge, 1869). A whole literature arose around the name of Clemens in subsequent times. Of this literature the following portions have come down to us. 1. A second Epistle to the Corinthians, found along with the first in the Codex Alexandrinus. As far as one can judge from the writing itself, this work is rather a homily than a letter. In all probability its author belonged to Egypt. Various suppositions have been made as to its authorship, but none that commands the assent of a considerable number of critics. It seems to have been written towards the middle or end of the 2d century. 2. Two letters on Virginity, found in Syriac. There is no external testimony that Clemens was the author of these letters, and they breathe a spirit of asceticism and dislike of marriage different from that prevalent in the early times of Christianity. They also refer to customs of a later date. Notwithstanding this, some critics, especially some Roman Catholics, have keenly defended their genuineness. 3. The *Clementines*. These appear in two forms: the *Recognitions* in Latin, and the *Homilies* in Greek. They are a fiction. The writer attempts to represent the state of the church as it was during the period between the ascension of Christ and the entrance of St Paul on his work as an apostle. St Peter is accordingly the hero of the work, and his great enemy is Simon the magician. The doctrines of the book are peculiar, and are most nearly allied to those that are reckoned to be the doctrines of the Ebionites. The question arises, Did the writer wish to represent the doctrines as the merely temporary doctrines of that period of transition? Or did he regard the doctrines which he has put forth in the work as the only true doctrines, and the subsequent doctrines of the Catholic Church as perversions of the true and aberrations from them? Baur and the Tubingen school have regarded the book as giving a genuine picture of the state of the early church and of Ebionitic doctrine, and a great part of their theory of the origin and rise of Christianity is based upon it. They suppose that in Simon the magician the writer has attacked the apostle Paul. Many critics suppose that the work was written at a very early period, but that it received numerous additions. As the work now exists, it seems to belong to the end of the 2d or beginning of the 3d century. 4. The *Apostolical Constitutions*. This work is a series of regulations in regard to the management of the church, such as the functions and character of bishops, presbyters, and deacons (see last article). In all probability the work was the result of one addition after another made to an originally small nucleus. Some assign portions of it to the apostolic age. Whiston thought that it was inspired. Most probably the main portion of it belongs to the 3d century. There is no reason for connecting with it the name of Clemens, though this was done by ancient writers. We should add to this list that some ascribed the canonical Epistle of the Hebrews to Clemens Romanus.

Ignatius.—The information we get in regard to Ignatius up till the time of Eusebius is exceedingly scanty. He is mentioned in the epistle of Polycarp. Origen speaks of him in two passages, which, however, may possibly be interpolations. Eusebius in his *Chronicon*, at the year 70 or 71 A.D., states that he was appointed bishop of Antioch, and at the year 109 A.D., that he suffered martyrdom. He repeats the same statements in his *Ecclesiastical History*, introducing his account of the martyrdom with the words, "The story goes." After the time of Eusebius our information becomes much more precise and minute. The birthday of the martyr (*i.e.*, the day of his martyrdom) was celebrated in the church of Antioch. Speeches were delivered in his praise. Wonderful stories were told of him. He was one of the children whom Christ took up in his arms and blessed. He introduced antiphonal chants into the service of the church, because he had seen a vision of angels praising God in antiphonal hymns. The details of his martyrdom are given in a document devoted to the purpose. Of this document there are eight forms; but one is generally believed to be better than the rest. This one states that Trajan, in the ninth year of his reign, was in Antioch, that Ignatius was brought before him, and that the emperor condemned the bishop to be sent to Rome, and to be exposed to the wild beasts. The writers then describe the journey of Ignatius to Rome, mention various letters which he wrote on the way, and then narrate his exposure to the wild beasts, and how they saw him afterwards in a vision. The letters of Ignatius cause great difficulty to the critic. Eight of the letters ascribed to him are now universally rejected. There remain seven others. These seven appear in two Greek forms, a longer and a shorter. Latin translations of these forms are found, and they differ somewhat from the Greek. And of the seven letters three are found in Syriac, and the Syriac form is much shorter than the shortest of the Greek. Which are the original letters? Or have we the original letters at all? Unfortunately before the time of Eusebius there is no external testimony to these letters that can give us any clue to the true nature of the text. And the testimony of Eusebius is of little value. He states distinctly that there were seven letters. But the critics who maintain that the seven shorter Greek letters are largely interpolated, have no hesitation in agreeing to the opinion that these interpolations were made before the time of Eusebius. The shorter form unquestionably belongs to the 2d or 3d century, most probably to the 2d. A few critics have maintained that the longer form is the genuine. A very large number of critics regard the shorter Greek form as the original form, though almost all allow that there are some traces of interpolation even in the shorter epistles. Other critics maintain that the shorter Syriac forms are alone genuine, that they are not epitomes, but the original letters, and they appeal to the circumstance that all the references to the epistles up to the time of Eusebius belong exclusively to the three Syriac epistles. The question is embittered by a keen controversy in regard to Episcopacy, the Ignatian letters being supposed to afford strong evidence of the early institution of that form of church government. The longer text was first known to scholars. Usher discovered a Latin version of the shorter form, and Vossius the Greek original of this version. Tattam found the Syriac translation in an Egyptian monastery, and Cureton edited it in 1845. Cureton's services in connection with Ignatius deserve the highest praise; and his *Corpus Ignatianum* contains almost all the evidence that can be brought to bear on the subject. The contest in regard to Ignatius's writings has been keen in various periods of the church's history; and since the Syriac version appeared, the subject has been discussed by a host of writers, among whom may be mentioned Bunsen, Baur, Dusterdieck, Denziger, Hilgenfeld, Lipsius, Ritschl, Merx, Nirschl, Zahn, and Newman.

Polycarp was bishop of Smyrna. The principal part of the information we have in regard to him is derived from Irenæus, and may be accepted with confidence. Irenæus knew Polycarp personally, and remembered how Polycarp "related his intercourse with John and the rest who had seen the Lord." The apostles appointed Polycarp a bishop of the church in Smyrna, and he remained there a long time teaching the truth. In the time of Anicetus, Polycarp came to Rome, and showed a strong spirit of love and charity, which was fully reciprocated by the Roman bishop. They differed in regard to the celebration of the day of the passover, but their differences did not interfere with their love for each other. A special document describes the martyrdom of Polycarp. There are good reasons for doubting the minute accuracy of this work, but the main circumstances have the appearance of being true. A persecution had arisen in Smyrna against the Christians, and naturally a demand was made for Polycarp, the chief of the Christians. At first he fled, but finding that this was of no use, he allowed himself to be apprehended and brought back. He was led before the proconsul, and urged to swear by Cæsar and revile Christ. "Eighty and six years," said Polycarp, "have I served Him, and He has done me no ill, and how can I blaspheme my King who has saved me?" The multitude wished the Asiarch to expose the bishop to the lions, but the Asiarch refused, as the time for lions was over. So the people gathered wood and lighted a fire. And Polycarp was placed in the fire, and ultimately also stabbed. The date of his martyrdom has been matter of keen discussion. Eusebius fixed it at 166 A.D. The *Martyrium* mentions that it took place in the proconsulate of Statius Quadratus. Recently Waddington has tried to show that Quadratus was proconsul in 154–5, and Lipsius has based on this result the conclusion that Polycarp suffered martyrdom in 155. This date, however, is open to serious objections; and even Waddington's reasons for placing the proconsulate of Quadratus in 154–5, are not of a satisfactory nature. The only writing that can be now attributed to Polycarp is a letter to the Philippians. This letter is mentioned by Irenæus and by subsequent writers. Jerome mentions that it was read in the churches. It is a simple outpouring of ordinary Christian thought and feeling. The Tübingen School deny the genuineness of the epistle on internal evidence. Ritschl has tried to show that it is largely interpolated, and there are strong reasons for believing the thirteenth chapter an interpolation.

Barnabas.—There has come down to us a work called the *Epistle of Barnabas.* This work is unanimously ascribed to Barnabas, the companion of St Paul, by early Christian writers. Clemens Alexandrinus quotes the letter seven times, and speaks of it as the work of the apostle Barnabas. Origen, Eusebius, and Jerome mention it. The internal evidence is conclusive against its genuineness. The writer regards the Jews as entirely wrong in having practised the ceremonial law. He thinks that Moses never intended that the precepts of the law should be carried out literally. They were to be understood from the first spiritually. By this literal interpretation the Jews had forfeited all claim to the covenant The covenant belongs only to Christians who obey the law in spirit. The writer applies this principle to sacrifices, circumcision, and the Sabbath. It is difficult to imagine that Barnabas could have adopted such a mode of viewing the law. In all probability he adhered to some of the Jewish practices to the end of his days. Moreover, the writer commits such mistakes in relation to the Jewish ritual as no Jew would commit who had had practical experience of it. Some of the opinions in the letter, and the whole tone of thought indicate that the writer had strongly felt the influence of Alexandrian Judaistic speculation. Accordingly, some critics have maintained that it was written in Alexandria. There is no clue to a date; but there are various indications which have been differently interpreted by different critics. Some, as Weizsäcker, have assigned it to the reign of Vespasian; others, as Wieseler, to the reign of Domitian; but the great majority of critics assign it to the reign of Hadrian, some time between 119 and 126 A.D. The letter consists of two parts. The latter part is somewhat different in style and purport from the former, and, accordingly, doubts have been entertained as to its genuineness. But there is no good reason for doubt, and external testimony is in favour of it. The first five chapters were extant only in the Latin translation until Tischendorf discovered the entire Greek of the first part in the *Codex Sinaticus.* The letter is interesting, as throwing light upon a peculiar phase of theological speculation in the early church.

Hermas.—The *Pastor of Hermas* is one of the most interesting books of Christian antiquity. The name Hermas occurs several times in the work, and it was therefore natural for the ancients to suppose that this was the name of the author. The book at a very early period became widely known in the East, and was regarded as inspired. Irenæus, Clemens Alexandrinus, and Origen speak of it and quote it as Scripture, and Eusebius uses somewhat similar language in regard to it. Origen asserts his belief that the author was the Hermas mentioned in the Epistle to the Romans. The African Church held a different opinion in regard to it. Tertullian speaks slightingly of it; and the story became current that it was written by a Hermas, who was brother to Pius, bishop of Rome from 140 to 155 A.D It may be doubted whether the author has really given his name. The work is fictitious in form, and there is no good reason for supposing that he has introduced any real characters into it. There is no clear indication of a date; but various circumstances lead to the inference that it was written towards the end of the reign of Hadrian, or the beginning of the reign of Antoninus Pius. Internal evidence points strongly to Italy as the place in which it was written. The book is divided into three parts: visions, commandments, and similitudes. It was very popular with the ancient church, and deservedly so. It presents Christian truth in an attractive manner. Its tone is high and noble, and it breathes the spirit of the gospel of love. The name of Christ does not occur in it, and as the references to the Son of God are few, some have characterised the book as strongly Judaistic. Indeed, various heresies and heretical tendencies have been discovered in it by keen-eyed critics; but as Clemens Alexandrinus and Origen failed to see them, and as the great mass of the early church accepted it as eminently fitted to edify, we cannot but think that the critics are wrong. The *Pastor of Hermas* has come down to us in several Latin translations. Simonides was the first to give us any portion of it in Greek. He brought three leaves of a codex of it from Mount Athos, with a copy of a considerable portion of the rest. The remainder of the Athos MS. has not been discovered. Tischendorf found a large portion of the *Pastor of Hermas* in Greek at the end of the *Codex Sinaiticus.* The Greek is very nearly the same as the Greek of Simonides.

There are numerous editions of the works of the apostolic fathers, but special mention may be made of those of Cotelerius, Hefele, Dressel, Hilgenfeld, and Jacobson. Professor Lightfoot's *Clemens Romanus* is the first part of what promises to be the most satisfactory edition of the apostolic fathers. Translations of all the works mentioned in this article, including the writings attributed to Clemens, are given in Clark's Ante-Nicene Christian Library; and the works are discussed in Hilgenfeld's *Apostolische Väter*, 1853, and Donaldson's *Apostolical Fathers*, 1874. (J. D.)

APOSTOLICI, or APOSTOLIC BRETHREN, a name assumed by three different sects, which professed a close adherence to the doctrines and practice of the apostles. The earliest, known also as the *Apotactici*, were a branch of the Encratites, and came into existence in the 3d century. According to Epiphanius, their principles were communistic. The second sect of the name was formed in the district surrounding Cologne about the middle of the 12th century. Its members were zealous reformers, rejecting the authority of the Pope and the rites and ceremonies of the church. It is not certain that they absolutely rejected marriage, though they preferred celibacy. Founding on the authority of St Paul, the celibates took spiritual sisters, with whom they lived in concubinage. Bernard of Clairvaux wrote against the sect, and some of its most prominent members being brought before the archbishop of Cologne were condemned to the flames. The third sect of Apostolici in chronological order was founded by Gerhard Segarelli, a mechanic of Parma, towards the close of the 13th century. Segarelli, who had sought admission unsuccessfully to the Franciscan order, was much impressed, it is said, by a picture of the apostles which hung in the Franciscan chapel at Parma. Becoming convinced that the much-needed reform of the church could only be effected by a return to the apostolic practice, he sought to establish a community in which the life of the apostles should be imitated as closely as possible. By slow degrees he gathered a considerable number of followers, chiefly from the lower orders, who went about from place to place clad in white robes, with long beards, dishevelled hair, and bare heads, accompanied by women whom they called their spiritual sisters. Like the other two sects of the same name, they established a community of goods. Though their practice was thus peculiar, their doctrinal teaching did not for a considerable period seriously diverge from the orthodox standard. The arrest of their leader by the bishop of Parma (1280), and condemnatory decrees issued by Honorius IV. (1286) and Nicolas IV. (1290), changed their position into one of open hostility to the Church of Rome. Accepting the predictions of the Abbot Joachim of Flora, they looked for the downfall of the papacy, which they described as the Babylon of Scripture, and the establishment of a new and purer church upon its ruins. Segarelli was accused of heresy in 1294, but escaped for the time by recantation. In 1300, however, he was condemned as a relapsed heretic to the flames. His place was immediately taken by Dolcino of Novara, the natural son of a priest, under whom the sect became still larger and more formidable. He seems to have been a man of superior power to Segarelli in all respects, and especially to have had considerable talent as a military leader, having succeeded in carrying on a war for two years against Raynerius, bishop of Vercelli. In 1307 he was defeated, taken prisoner, and put to a cruel death at Vercelli. The name "Dolcinists," frequently applied to the sect, marks the extent of Dolcino's influence, as does also an allusion to him in Dante's *Inferno.* The sect of the Apostolici maintained its existence in spite of continual persecution until the beginning of the 15th century, when it became extinct or was merged in other sects. (See Muratori's "Historia Dulcini," in his *Rerum Italicarum Scriptores*, ix. § 425; Mosheim's *Geschichte des Apostelordens*, 1748; Neander's *Church History*, vol. viii.; Mariotti's *Fra Dolcino and his Times*, 1853; Milman's *Latin Christianity*, vol. vii.)

APOSTOLIUS, MICHAEL, a Greek theologian and rhetorician of the 15th century. When, in 1453, the Turks made themselves masters of his native city, Constantinople, he fled to Italy, and there obtained the protection of Cardinal Bessarion. But engaging in the great dispute that then raged between the upholders of Aristotle and Plato, his zeal for the latter led him to speak so disrespectfully and contemptuously of the more popular philosopher and his defender, Theodorus of Gaza, that he fell under the severe reprehension of his patron, who was too thoroughly a follower of Plato to wish his cause to be maintained by weapons so unworthy. He afterwards retired to Crete, where, with a "proud humility," he earned a scanty living by the teaching of children and the copying of manuscripts. Many of the productions of his pen are still to be found in the libraries of Europe. One of them, a copy of the *Icones* of Philostratus at Bologna, bears the inscription: "The king of the poor of this world has written this book for his living." Of his numerous works a few have been printed:—*Παροιμίαι*, Basle, 1538, now exceedingly rare; a collection of proverbs in Greek, of which a fuller edition appeared at Leyden, "Curante Heinsio," in 1619; *Oratio Panegyrica ad Fredericum III.* in Freher's *Scriptores Rerum Germanicarum*, vol. ii., Frankfort, 1624; Georgii Gemisthi Plethonis et Mich. Apostolii *Orationes funebres duæ in quibus de Immortalitate Animæ exponitur*, Leipsic, 1793; and a work against the Latin Church and the Council of Florence in Le Moine's *Varia Sacra.* Apostolius died about 1480, leaving two sons, Aristobulus Apostolius and Arsenius. The latter became bishop of Malvasia (Momembasia) in the Morea.

APOTHECARY. This name is derived from the Greek Ἀποθήκη, a word used by Galen to denote the repository where his medicines were kept. In Scotland the term is often applied to one who compounds and sells drugs, but this class is now defined in the language of some recent Acts of Parliament as pharmaceutical chemists, and chemists and druggists, both in England and Scotland. In England the name indicates a general practitioner in medicine who supplies drugs to his patients. The Apothecaries' Society of London is one of the corporations of that city, and both by Royal Charters and Acts of Parliament exercises the power of granting licences to practise medicine. The members of this society do not possess and never have possessed any exclusive power to deal in or sell drugs; and until very lately (1868) any person whatever might open what is called a chemist's shop, and deal in drugs and poisons. In that year, however, the Pharmacy Act was passed, which prohibits any person from engaging in this business without being registered.

From early records we learn that the different branches of the medical profession were not regularly distinguished till the reign of Henry VIII., when separate duties were assigned to them, and peculiar privileges were granted to each. In 1518 the physicians of London were incorporated, and the barber-surgeons in 1540. But, independently of the physicians and the surgeons, there were a great number of irregular practitioners, who were more or less molested by their legitimate rivals, and it became necessary to pass an Act in 1543 for their protection and toleration. As many of these practitioners kept shops for the sale of medicines, the term "apothecary" was used to designate their calling.

In April 1606 James I. incorporated the apothecaries as one of the city companies, uniting them with the grocers. On their charter being renewed in 1617 they were formed into a separate corporation, under the title of the "Apothecaries of the City of London." These apothecaries appear to have prescribed medicines in addition to dispensing them, and to have claimed an ancient right of acting in this double capacity; and it may be mentioned that Henry VIII., after the grant of the charter to the College of Physicians, appointed an apothecary to the Princess Mary, who was delicate and unhealthy, at a salary of 40 marks a year, "*pro meliore curâ et consideratione sanitatis suæ.*" During the 17th century, however, there arose a warm contest between the physicians and the apothecaries,—the former accusing the latter of usurping their province, and the latter continuing and justifying the usurpation until the dispute was finally set at rest by a judgment of the House of Lords in 1703, when it was decided that the duty of the apothecary consisted not only in compounding and dispensing, but also in directing and ordering the remedies employed in the treatment of disease. In 1722 an Act was obtained empowering the Apothecaries' Company to visit the shops of all apothecaries practising in London, and to destroy such drugs as they found unfit for use. In 1748 great additional powers were given to the company by an Act authorising them to appoint a board of ten examiners, without whose license no persons should be allowed to dispense medicines in London, or within a circuit of 7 miles round it. In 1815, however, an Act of Parliament was passed which gave the Apothecaries' Society a new position, empowering a board, consisting of twelve of their members, to examine and license all apothecaries throughout England and Wales. It also enacted that, from the 1st of August of that year, no persons except those who were so licensed should have the right to act as apothecaries, and it gave the Society the power of prosecuting those who practised without such license. But the Act expressly exempted from prosecution all persons who were then in actual practice, and it distinctly excluded from its operation all persons pursuing the calling of chemists and druggists. It was also provided that the Act should in no way interfere with the rights or privileges of the English Universities, or of the English College of Surgeons or the College of Physicians; and indeed a clause imposed severe penalties on any apothecaries who should refuse to compound and dispense medicines on the order of a physician, legally qualified to act as such. It is therefore clear that the Act contemplated the creation of a class of practitioners who, while having the right to practise medicine, should assist and co-operate with the physicians and surgeons.

Before this Act came into operation the education of the medical practitioners of England and Wales was entirely optional on their own part, and although many of them possessed degrees or licences from the universities or colleges, the greater number possessed no such qualification, and many of them were wholly illiterate and uneducated. The Court of Examiners of the Apothecaries' Society being empowered to enforce the acquisition of a sufficient medical education upon its future licentiates, specified from time to time the courses of lectures or terms of hospital practice to be attended by medical students before their examination, and, in the progress of years, regular schools of medicine were organised throughout England.

As it was found that, notwithstanding the stringent regulations as to medical acquirements, the candidates were in many instances deficient in preliminary education, the Court of Examiners instituted, about the year 1850, a preliminary examination in Arts as a necessary and indispensable prerequisite to the medical curriculum, and this provision has been so expanded that, at the present day all medical students in the United Kingdom are compelled to pass a preliminary examination in Arts, unless they hold a university degree. An Act of Parliament, passed in 1858, and known as the Medical Act, made very little alteration in the powers exercised by the Apothecaries' Society, and indeed it confirmed and in some degree amplified them, for whereas by the Act of 1815, the licentiates of the Society were authorised to practise as such only in England and Wales, the new measure gave them the same right in Scotland and Ireland.

A still more recent Act, passed in 1874, relates exclusively to the Apothecaries' Society, and is termed the Apothecaries' Act Amendment Act. By this measure some provisions of the Act of 1815, which had become obsolete or unsuited to the present times, were repealed, and powers were given to the Society to unite or co-operate with other medical licensing bodies in granting licences to practise. The Act of 1815 had made it compulsory on all candidates for a licence to have served an apprenticeship of five years to an apothecary, and although by the interpretation of the Court of Examiners of the Society this term really included the whole period of medical study, yet the regulation was felt as a grievance by many members of the medical profession. It is accordingly repealed, and no apprenticeship is now necessary. The restriction of the choice of examiners to the members of the Society is also repealed, and the Society has moreover the power (which it did not before possess) to strike off from the list of its licentiates the names of disreputable persons. As a question was raised, under the Act of 1815, whether women were admissible as candidates for the medical licence (owing to the ambiguous wording of the measure), and as the society, acting under legal advice, had admitted a woman to the licence, the Act of 1874 refers to the point, but leaves it still undecided, merely specifying that the new Act does not deprive the Society of any right or obligation they may have to admit women to examination, and to enter their names on the list of licentiates if they acquit themselves satisfactorily.

APOTHEOSIS, deification, the enrolment of a mortal among the gods. In its most rudimentary form, this practice may be regarded as an offshoot of the universal belief of primitive mankind in the existence of disembodied spirits, and their continued agency in human affairs. (Tylor, *Primitive Culture*, ch. xi.–xvii.) An invisible being thus invested with beneficent or malefic attributes, and capable of being offended or propitiated, virtually becomes a local or tutelary divinity. The cultus of such genii constitutes a large part of the religion of most negro nations. In China it takes the shape of a respectful veneration of ancestors, accompanied by a species of liturgical service. In India it is apparently excluded by the tenet of incarnation, according to which the individual either resumes a rank previously held by him, or enters upon a cycle of transmigrations admitting of no fixity of condition and, consequently, of no absolute deification. The Egyptian, Persian and Phœnician theologies seem to offer no trace of the idea; but there is reason to expect that it will be shown to have been a leading feature of the religions of Assyria and Babylon. For perfectly unequivocal examples of its prevalence among a highly cultivated people, we must resort to Greece and Rome. In Greece the worship of deified heroes was universal. A distinction, however, must be observed between the imaginary patriarchs of the golden age, who, after their decease, according to Hesiod (*Op. et Dies*, 121), became by the counsel of Zeus beneficent dæmons, guardians of mortal men, but who seem to have enjoyed only a vague and general veneration, and the mythical heroes, definite objects of worship, who may have been equally apocryphal, but whose legends were none the less regarded as authentic history. The reputed founders of cities were especially honoured with sacrifices by their descendants, and the practice extended to such indubitably historical personages as Lycurgus, Brasidas, Harmodius, Aristogiton, and Ptolemy Lagus. Instances of the origination of such worship in the historical period are nevertheless rare, and the veneration paid to the hero was in all cases merely local. The religious honours subsequently bestowed in their lifetime on Lysander, Alexander the Great, and other illustrious persons, were merely the extravagance of flattery, devoid of any influence on the national theology. The same cannot be said of the apotheosis of the Cæsars, the germ of which already existed in the veneration paid to the legendary founder of Rome. To the Roman the emperor appeared as the visible manifestation of the genius of the state, long the object of his reverence. (Friedländer, *Sittengeschichte Roms*, vol. iii. p. 455.) The people, says Suetonius, fully believed in the divinity of Julius Cæsar, hinting at the same time that this was by no means the case with the majority of the apotheoses subsequently decreed by the senate. (*Jul. Cæs.* c. 88.) The honour was indeed not only conferred upon almost every emperor who transmitted the sceptre to his descendants, but frequently upon deceased members of his family, or even his personal favourites, as in the case of Antinous. Sixty persons altogether are recorded as having been thus raised to divine honours from the time of Cæsar to that of Constantine. The majority of such apotheoses would be regarded as mere matters of official form; in some instances, however, it was otherwise. We learn from Capitolinus that Marcus Aurelius was still worshipped as a household divinity in the time of Diocletian, and was believed to impart revelations in dreams. (*Vit. M. Ant.* c. 18.) Antinous was adored in Egypt a century after his death (Origen, *Contra Celsum*, iii. 36). The ceremonies attendant on an imperial apotheosis are very fully described by Herodian (lib. iv. c. 2) on occasion of the obsequies of Severus, which he appears to have witnessed. The most significant was the dismission, at the moment of kindling the funeral pyre, of an eagle which was supposed to bear the emperor's soul to heaven. Sharp-sighted persons had actually beheld the ascension of Augustus (Suet., *August.* c. 100), and of Drusilla, sister of Caligula; the latter eyewitness took the public incredulity exceedingly amiss (Seneca, *Apocolocyntosis.*) The ludicrous side of the deification of a bad or indifferent emperor could escape no one, and is pungently illustrated by Seneca in the witty lampoon just quoted: even here, however, it is laid down that *principes pietate et justitia dei fiunt*. Representations of apotheoses occur on several works of art; the most important are the apotheosis of Homer on a relief in the Townley collection, and that of Augustus on a magnificent cameo in the Louvre. The establishment of Christianity put an end to apotheosis as an avowed belief and a public ceremony, although the principle on which it rested is still conspicuous in the adoration and invocation of saints by the Latin, Greek, and African Churches. The commemoration of Auguste Comte by his followers may be cited as another instance in point. The worship of Ali and his sons by some Persian sects, and that of the Caliph Hakem by the Druses, are not properly examples of apotheosis, being rendered to them not as deified mortals, but as incarnations of the Deity. (R. G.)

APPALACHIAN MOUNTAINS, the general name given to a vast system of elevations in North America, partly in Canada, but mostly in the United States, extending for 1300 miles, from Cape Gaspé, on the Gulf of St Lawrence, south-west to Alabama. The whole system may be conveniently divided into three great sections: the *Northern*, from Cape Gaspé to New York; the *Central*, from New York to the valley of the New River; and the *Southern*, from the New River onwards. The first of these includes the Adirondacks, the Green Mountains, and the White Mountains, and the irregular elevations towards the north: the central contains a large portion of the Blue Ridge, the Alleghanies proper, and a great number of lesser ranges: and the southern consists of the prolongation of the Blue Ridge, the Black Mountains, the Smoky Mountains, and the Unaka Mountains. The whole range, and especially the central portion, is remarkable for the parallelism of the various ridges, the uniform height of the summits in the same part of the chain, the absence of a central axis of elevation, and the presence, instead, of a central valley or axis of depression. The typical arrangement of the system—most distinctly visible in the central division—might be represented in diagram thus. first, a stretch of country, gradually sloping, with slight undulations and irregularities, upwards from the Atlantic, and attaining a height of 300, 500, or 1000 feet; then, a lofty ridge rising like a rampart, and succeeded by other ridges separated from each other by longitudinal valleys; next, the great central valley or axis of depression; and lastly, a new succession of ridges breaking off into table-land with transverse valleys and a gradual decrease of elevation. The Atlantic slope varies in breadth from 50 miles, as in New England, to 200 miles, in the south, and in the neighbourhood of New York has almost altogether subsided. The central valley may be traced from Lake Champlain in the north, along the course of the Hudson, down through the Cumberland Valley, in Pennsylvania, and the Great Valley of Virginia and Tennessee; it varies in breadth from 15 miles in the north to 50 or 60 miles in the south. The elevation of the valley rises towards the south in keeping with the elevation of the neighbouring ranges. None of the summits of the system reach the region of perpetual snow, but a large number of them attain a considerable altitude. In the Adirondacks the highest point, Mt. Tahawus or Mt. Marcy, reaches 5379 feet. In the White Mountains, Mt. Washington, in the main chain, has a height of 6288 feet; Mt. Adams, 5794; Mt. Madison, 5365; Mt. Jefferson, 5714; Mt. Clay, 5553; Mt. Monroe, 5384; Lafayette, 5290; and a great number of summits attain a height of more than 4000 feet. In the Green Mountains the highest point, Mt. Mansfield, is 4430 feet; Lincoln Mount, 4078; Killington Peak, 4221; Camel Hump, 4088, and a number of other heights upwards of 3000 feet. In the central division the hypsometric surveys are imperfect; but the general elevation of the higher chains is from 1000 to 2500 feet. As we approach the south, the complexity of the system and the altitude of the individual mountains increase together, and the chains which have run parallel and distinct begin, as it were, to gather and fold themselves into an irregular coil. The peaks of Otter in Virginia are about 4000 feet high; and in the Black Mountains, the Black Dome (Clingmann), which is the culminating point of the whole system, attains the height of 6707 feet; Balsam Cone (also known as

Guyot, from the hypsometrical explorer of the region) has 6671; Black Brother, 6619; and Mt. Hallback (Sugarloaf), 6403; besides a large number of summits varying from 3000 up to 6000 feet. In the Smoky Mountains we have Clingmann's Dome, 6660 feet high; Guyot (in Tennessee), 6636; Mt. Alexander, 6447; Mt Leconte, 6612; Mt Curtis, 6568; several others upwards of 6000, and a great many of more than 5000. In the whole Appalachian system, Lake Champlain is almost the only lake of any importance; but a multitude of rivers, and some of them of considerable size, find their sources in its recesses. The watershed does not lie along any one continuous axis, but shifts its position several times along the line. In the north it is found in a stretch of country, called the Height of Land, that lies between the White and the Green Mountains, and gives birth to the Connecticut and a number of smaller streams; next, it is formed by the Adirondack Mountains, which supply the sources of the Hudson River; and, further south, by the high plateaus of Pennsylvania and New York, which give origin to the Delaware and the Susquehanna, with their numerous tributaries. These rivers, flowing south and east, have thus to cut their way through the successive ridges of the whole Appalachian range. The watershed is next situated in the Alleghanies proper, which send a number of affluents to the Ohio on the west, and give rise to the James River on the east; and lastly, it runs along the terminal cluster or coil composed of the Black, the Smoky, and the Unaka Mountains. Here a tributary of the Ohio, called the Red River, a number of the affluents of the Tennessee, and various less important streams, have their sources. The Appalachian Mountains are a vast storehouse of mineral wealth. Magnetite, hematite, limonite, and other iron ores, are found in great abundance. The first is best exhibited in what is frequently called the Champlain Iron District, where it is now largely manufactured; and it also attains remarkable development in various parts of New York and New Jersey. The extensive deposits of this ore in Virginia, North Carolina, and Georgia, have hitherto been turned to comparatively little account. It is frequently contaminated by phosphate of lime, sulphur, and titanium. Red hematite is found in New York, Pennsylvania, Tennessee, and Georgia, and is usually known as Clinton ore, from a place of that name in Madison County, New York, while in Tennessee it is called Dyestone ore. It is of great commercial importance, though, on account of the amount of phosphorus which it contains, it is worthless for the manufacture of steel. Limonite, or brown hematite, which, from its fusible character, is usually worked along with the more crystalline ores, occurs in a series of beds all along the flanks of the Appalachians, from Maine in the north to Georgia in the south. The earthy carbonate of iron—"clay ironstone ore," "shell ore," "kidney ore," —is found in most parts of the system in connection with the Carboniferous strata, and has been very largely manufactured. In the northern district alone—that is, in the eastern part of New York, in New Jersey, and Eastern Pennsylvania—the number of furnaces is about 200, and the gross production of iron 900,000 tons per annum, or one-third of the entire production of the United States. This abundance of ore would have been almost useless had it not been for the equally abundant supplies of fuel; and the coal measures are among the most extensive in the world, the bituminous coal alone covering an area of 56,000 square miles, without counting the unrivalled beds of anthracite in Pennsylvania and New York, which cover an area of between 400 and 500 miles. While the supply of gold, silver, copper, and lead is of comparatively no importance, marble, limestone, fire-clay, gypsum, and salt are extremely abundant. Many of the ranges are richly covered with forest, and yield large quantities of valuable timber, consisting chiefly of sugar maple, white birch, beech, and ash, in the north, and oak, cherry-tree, white poplar, white and yellow pine, towards the south. The dark foliage of the pines, balsam-firs, hemlock-trees, and cedars, gives colour and name to many of the districts. Rhododendrons, kalmias, azaleas, and other flowering shrubs, often grow in almost impenetrable thickets; and in some parts the botanist is at once delighted and bewildered by the profusion and variety of the smaller plants. Bears, "panthers," wild cats, and wolves haunt the forests in large numbers.

The Appalachian system has a history which is of great interest, as it affords the clue to the causes of its formation; but a few points only can be touched on here. The earliest strata in the range are of Upper Cambrian age, and during the later portion of this period the Potsdam sandstone was deposited, the nature of which demonstrates that a large portion of the United States was then a shallow sea. Upon this were superimposed strata of Silurian, Devonian, and Carboniferous age, but these deposits were by far the thickest along the broad band now occupied by the Appalachians, and where thickest they have the general character of shallow water-beds. Beds of the same age occupy the valley of the Mississippi; there they are largely composed of limestones and deep water-beds, and have an aggregate thickness of about 8000 feet, usually horizontal or only slightly inclined. In the Appalachian Mountains their aggregate thickness is 40,000 feet, and the beds are thrown into complicated folds and contortions. At the close of the Carboniferous Period the beds were deposited in shallow water, and hence there must have been a subsidence along the band whereby the Potsdam sandstone and its associated rocks were depressed from 30,000 to 40,000 feet below the sea-level. This depression threw the strata into one gigantic synclinal basin, to conform to which the beds were necessarily crumpled up, and at the same time more or less metamorphosed. Then the beds began to rise above the sea-level, and the valleys and ridges to be formed, a process which may have been one of slow development, but which had made considerable advance prior to the Triassic age, when sandstones were deposited in the Appalachian valleys. The elevation has continued until the Potsdam sandstone is now a few hundred feet above the sea. If the strata had retained their original character and planes of deposition relatively to the horizon, the highest mountains would have reached 40,000 feet; but, as we have seen, they actually attain but 6707 feet. The elevation was not confined to the line of the Appalachians, but was continental in extent. During the process of elevation denudation was in operation, and by this agency the surface features of the range generally have been moulded. From this brief summary some idea may be conceived of the numerous operations and circumstances involved in the formation of a mountain chain like the Appalachians, which are intermediate in nature and in age between the older Laurentides, which are now worn down almost to a stump, and the Rocky Mountains, which have an air of comparative freshness. (For fuller details on this subject, consult the references given below and the separate articles on the States in this work:—Petermann's *Mittheilungen*, 1860, p. 263; *The American Journal of Science*, vol. xxxi. p. 157, and p. 392, 1861; Roger's *Report on the Geology of Pennsylvania*, 1858; a paper by Dana in the *American Journal of Science*, vol. xxxvi. p. 227, 1863; Hall, *Palæontology of New York*, vol. iii.; Sterry Hunt's "Geognosy of the Appalachian System," in his presidential address, *Proceedings of American Association for the Advancement of Science*, for 1872, p. 3.)

APPARITIONS

APPARITIONS, in the ordinary acceptation of the word, can scarcely be better defined than in the terms used by Defoe: "They are the invisible inhabitants of the unknown world, affecting human shapes or other shapes, and showing themselves visibly to us." In this definition no account is taken of "spectral illusions, involuntarily generated, by means of which figures or forms, not present to the actual sense, are nevertheless depicted with a vividness and intensity sufficient to create a temporary belief of their reality." Theories of apparitions generally deal with these hallucinations, and no doubt they are the foundation of many of the stories of superstition, but they scarcely suffice to account for the universality of the belief in the possible appearance of disembodied spirits. These figures, kind or threatening, are probably the first objects that meet the vision of primitive men, when they begin to reflect on the unseen powers around them, and "to explore these coasts which our geographers cannot describe." Ghosts are almost the first guess of the savage, almost the last infirmity of the civilised imagination; on these forms, shadowy and unsubstantial as they are, solid superstructures of ritual and morality have been based, and apparitions, with the consequences of the belief in them, have a literature and a history of their own.

In the first place, the belief has had an immense effect on the religious and moral development of our race. Though it is as yet impossible to analyse to its first elements the confused mass of fear and custom which makes up the faith of savages, there can be little doubt that their religion, with the later and refined heathenism of Greece and Rome, sprang in part from the propitiation of the spirits of ancestors. Again, it would no longer be true to say, as Scott did forty years ago, that "the increasing civilisation of all well-constituted countries has blotted out the belief in apparitions." The visionaries who found their religion on a pretended intercourse with the dead, and who consider the highest function of their clergy to be "the serving of tables"—tables that rap and move—may be counted in America by millions. Many causes have combined to bring about this return to what a short time ago seemed a forlorn superstition. First, there was that reaction against the somewhat commonplace scepticism of the last century which took in literature the form of Romanticism and of the Gothic revival, and brought back in a poetical shape the fairies and spectres of mediæval fancy. Again, the lofty morality and pure life of Swedenborg (1688–1771) won a hearing for his extraordinary visions, and minds influenced by him were ready to welcome further additions to the marvellous. He declared that "the spirit of man is a form," and added that it had been "given to him to converse with almost all the dead whom he had known in the life of the body." Last of all came what is called spiritualism, inspired by an impatient revolt against the supposed tendencies and conclusions of modern science. Inquirers who live in constant fear that science is trying to demonstrate the truth of materialism, and to rob them of their dearest hope, that of a future life in the society of their departed friends, turn eagerly to what they think ocular evidence of another existence. There is scarcely any literature, not even the records of trials for witchcraft, that is more sad and ludicrous than the accounts of "spiritual séances," with the persistence of the bereaved in seeking a sign. The attempt of the Alexandrian Platonists to substitute the visions of trances for the conclusions of intellect has been called the despair of reason; and modern spiritualism, when it is not a drawing-room amusement, is too often a moment in the despair of faith.

The belief in apparitions, we have said, has its history, a history contained in ancient laws and literature, in the customs and superstitions of savages, and in the fireside ghost-stories of our own homes. By a comparison of all these we shall try, first, to show how the notion of the existence of spirits and of the possibility of their appearance arose; next, to trace several of the shapes in which it is most powerful and general; lastly, to point out how modern theories and marvels are connected with primitive and savage ideas, and we shall probably arrive at the conclusion that there is either some substratum of unexplained facts, or that the human imagination is subject to laws which have not been sufficiently investigated.

Primitive beliefs.

It would be rash to say, with Mr Herbert Spencer, that the propitiation of the spirits of ancestors is the first germ of all religion, and it would be premature to deny that there may be races which have no conception of the existence of the spirit after death. But it is safe to assert that there are very few savage peoples who do not believe that their dead ancestors appear to them in dreams, and in what they think the clearer vision of trances, and who do not prove their belief by sacrifice of food, by prayers for help, by hymns, and by offerings made to show love or deprecate anger. The wide-spread graves of extinct races, with the weapons and vessels buried along with the dead, demonstrate that these nameless and vanished hordes also held that the life of the dead persists, with its old needs and desires. The literature of cultivated peoples shows clearly that the Greeks and Romans held the same opinion, and practised no very different rites. It would be tedious and superfluous to state all the facts so carefully collected by Mr Tylor in his *Primitive Culture.* Enough to say that when the Athenians condemned the generals who neglected to bury the men who fell at Arginusæ, when Odysseus built a tomb in deference to the threat of the dead Elpenor—"lest I become a curse to thee, sent by the gods"—they acted from the same motive as the Australian "black fellow" who holds that his deceased tribesman, if left uninterred, will haunt him as an *ingna*, or mischievous spirit. If we wanted to state the savage theory of apparitions, we could scarcely do it better than in the words of Apuleius—"The human soul, after it has quitted the body, is called Lemur; that which undertakes the guardianship of the family is called Lar; those which wander without fixed homes are named Larvæ." The Lemurs then, we may say, are with us still as churchyard ghosts; the Lar, after becoming the venerated *hero* of Grecian religion, has departed with the advance of Christianity. An able account of the Greek worship of the dead will be found in *La Cité Antique*, by M. Fustel de Coulanges.

Taking it for proved that the credence in the apparitions and the power of the dead is a fact as good as universal in the beginning of thought, we must ask, How was the notion arrived at? Discarding for the moment the possibility that it was founded on actual apparitions, we observe several causes which might, indeed which *must*, have given rise to it. The savage, like the child, is full of questionings, and his reasonings are, so to say, perfectly rational. His hypotheses colligate and explain the facts, as far as he knows them. One of the earliest mysteries to him is the mystery of death—how is he to explain the sudden and eternal stillness of the warriors slain in battle? Now the savage philosopher knows of another state, namely, sleep, in which he *seems* as quiet as the dead, but is really active in dreams. Has he then two selves? The problem is that which Hartley Coleridge resolved when a child—"There is a dream Hartley, a shadow Hartley, a picture Hartley, a hold-me-fast Hartley." "When I sleep," then the savage may conclude, "one of my selves leaves the other to rest, and goes about its business. And in death, also, one self flies away, but it will not return—it is homeless, hungry, wandering. Above all, it is a very strange thing, and, as strange, to be feared." *A priori* reasoning goes as far as this, and then confirmatory facts support the hypothesis. In dreams he meets the dead warrior, and some of his friends have the same experience. And there is one of the tribe, the diviner or *shaman*, whose opinion they revere in these matters. He is thus described by a Zulu convert—"When he is awake he sees things which he would not see if he were not in a trance." He knows how to produce trances by fasting, by inhaling the smoke of herbs, and by the use of strange oils. He sees things before they happen, and tells how, when awake, he beheld the slain warrior, and promised to appease his hunger with sacrifice of cattle. There can scarcely be any other conclusion from these facts, as far as they are known to the savage, except that the dead yet live, and appear to the living, and keep their old passions and their old wants.

Now this belief in apparitions, thus stated, is capable of much development. The favourite ancestral spirit of the strongest tribe will tend to absorb the lion's share of sacrifice and hymns, and to become such a hero as Theseus was to the Athenians. Many other influences produce a still higher religion, a circle of Olympian gods, a philosophic and intellectual monotheism. The family of the seer will perhaps become a sacred caste, like the Eumolpidæ at Athens. An early civilisation is formed, with its philosophers, holding in secret a monotheism of their own, with its city population pleased by stately temples and hieratic splendours, but we must remember that all this time the *pagani*, the rural people of the hills and the coast, come very little under the influence of philosophy or of ritual. *They* still retain the old dread of the ghosts of the departed, and still people the woods and wells with wandering spirits. As slaves and nurses they enter the cultivated families, their old wives' fables impress the awakening imagination of childhood, and the earliest of all forms of belief in the supernatural finds its way back into the circle of culture. At last there comes a time of decadence, when the abstract notion of Deity seems too vague and distant, when the Olympian gods are no longer credible, and philosophy falls back in despair on the traditional ghosts of the nursery and of the Oriental slaves. Thus Neo-Platonism reinstated apparitions as demons, angels, powers; and thus Henry More and Joseph Glanvil combated the scepticism of the seventeenth century with stories of haunted houses, and of the mysterious drummer of Tedworth.

If this theory of the origin of the belief in apparitions be correct, it tends to explain what certainly is a difficulty—the *identity* of ghost stories in all lands and times, the conservatism of that great majority, the dead. For the further we go back in the history of civilisation, as in the works of nature, the simpler, the more identical, the more widely diffused are all its productions. The earliest implements for lighting fires, the earliest weapons, are not more alike than the earliest guesses of speculation and the earliest efforts of fancy. These oldest fancies dream of apparitions of the dead, and are preserved below the level of advancing culture, and insinuated into the ideas of the cultivated classes by the classes which are unprogressive, unaffected on the whole by religious or social changes It is for this reason that magical rites are everywhere the same, as M. Maury has observed—that the Scotch witch had the same spells as the Kaffir witch, that Balzac's description of a Parisian sorceress in *Le Cousin Pons* might serve as an account of a Finnish wise-woman. It is not strange that superstition and ignorance should always tell the same baseless tale if they have always treasured and still repeat the earliest and crudest fancies of the race. Nothing shows more clearly the purity of ancient culture than the absence of superstition in the Greek as compared with our Teutonic classics.

Supposing the origin of the belief in apparitions, and its identity in different peoples, to be thus accounted for, it remains to ask if the surviving forms of the creed can be traced back to a primitive source. In entering the cloud-land of folk-lore it is impossible to advance too cautiously. This is a realm where nothing is fixed and definite; where all is vague, floating, confused. He who would call up and try the spirits here must not place himself within too narrow a magic circle, but extend his view as far as possible to the beliefs of the most alien and distant races. The apparitions of popular superstition fall into classes which always tend to be merged in each other, but which are not so indistinct that they cannot be considered apart. No form is better known than the belief in fairies. All Fairies. over Europe fireside tradition tells of women who haunt lonely places, where they are seen to dance, to spin, to comb their long hair. They cause inexplicable nervous diseases—epilepsy and St Vitus's dance; they have a kingdom underground, whither they allure their lovers; they appear with fatal gifts at children's birth; they steal the children of mortals away, and leave changelings of their own. Our fathers dreaded them as *the good folk*, in Tweeddale and Ettrickdale; the Highlanders call them *the folk of peace;* in Greece they are *nereids;* in Servia, *vilis;* in Bretagne, *korrigans;* in Russia, *rusalkas.* They ought, if our hypothesis is correct, to be traceable to the lower spirits who in pagan times informed woods and wastes, and dwelt by the hearth; who had no temples to be overthrown or changed into Christian churches. The forests sheltered them when the fane of Jupiter fell, and the house of Theseus became the church of St George. The women concealed the hearth-spirit, as Rachel did Laban's gods, in the furniture of their houses. Rude and rustic people kept up the traditional belief, and the scant offering by the haunted well that the Highlanders of Perthshire still do not care to withhold. The capitularies of Liutbrand forbade such sacrifices; a series of councils repeated the prohibition. The result of these ecclesiastical allusions to "the lesser people of the skies" is that we can trace the French *fées* back to the *fata* of classical mythology. *Fées* in old French is *faés; faés* is the *fadæ* of Gervase of Tilbury in his *Otia Imperialia* (1220); *fadæ* is a corruption of *fata*, who are named with *bonæ, les bonnes dames* (the good ladies) among the superstitions of the Gauls. Such is the pedigree of the fées, as traced by M. Maury in his interesting tract, *Les Fées du Moyen Age.* Further information, to show the identity of the superstition, will be found in Scott's essay in the *Border Minstrelsy*, in Bernhard von Schmidt's *Peasant Life in Modern Greece*, in Pashley's *Travels in Greece*, in Ralston's *Folk-Songs of Russia*, and in the *Barzaz Breiz* of the Marquis de la Villemarqué. Now turn to Kaffir superstition. Dr Callaway, in the *Religious System of the Amazulu*, p. 226, writes thus:—"It may be worth while to note the curious coincidence of thought among the Amazulu regarding the *amatongo* or *abapansi* (ancestral spirits), and that of the Scotch or Irish regarding the fairies or 'good people. For instance, the 'good people' of the Irish have ascribed to them, in many respects, the same motives and actions as the *amatongo.* They call the living to join them, that is, by death; they cause diseases which common doctors cannot understand nor cure. The common people call them their friends or people, which is equivalent to the term, *abakubo*, given to the ancestral spirits. In the funeral procession of 'the good people' are recognised the forms of those who have just died, as Umkatshana, in the Zulu tale, saw his relations among the ancestral spirits. So also in the Highland tales. A boy who had been carried away by the fairies, on his return home speaks of them as 'our folks,' which is equivalent to *abakwetu*, applied to the ancestral spirits. The fairies are also called *ancestors*. 'The Red Book of Clanranald is said not to have been dug up, but found *on* the moss,' says Mr Campbell in the Tales of the West Highlands; 'it seemed as if the ancestors sent it.'" All these coincidences cease to be strange if we suppose that the Celtic people retain as subordinate and childish traditions the primitive beliefs which make the religion of the Kaffir.

Brownies. It would be easy to trace the belief in brownies (lubber spirits, who tend the house) to the lar, or hearth spirit of the ancients. The *domovoy*, or Russian brownie, "lives behind the stove; but he, or the spirits of the dead ancestors whom he represents, were held to be in even more direct relations with the fire on the hearth. In some districts tradition expressly refers to the spirits of the dead the functions which are generally attributed to the domovoy; and they are supposed to keep careful watch over the house of a descendant who honours them and provides them with due offerings. In some families a portion of the supper is always set aside for the domovoy; *for if he is neglected he waxes wroth, and knocks the tables and benches about at night.*" This is the account of Mr Ralston, which tallies with the Scotch stories of brownies, as with those of the Lithuanian *kanka*, the Finnish *paara*, the French *lutin*, and the humble Northumbrian *bogie*, who "flitted" with the farmer when he removed his furniture. All these are *lares*; and the ghastly superstition of the vampire, still prevalent in Greece as once in Scotland, may be traced to the unsatisfied *ingna*, or malevolent spectre of the Australian savage, the *tii* of Polynesia, the *upir* of Russian folk-lore.

Second sight. We now come to almost the most universally credited class of apparitions—namely, the subjective visions, coinciding with real facts and events occurring at a distance, beheld by persons possessing the Celtic *taishitaraugh*, or gift of second-sight. The second-sight is described by a believer as "a singular faculty of seeing an otherwise invisible object, without any previous means used by the person that beholds it for that end." The name of second-sight is the Scotch one under which the reputed phenomena excited the curiosity of Dr Johnson, and "made him wish to have some instances of that faculty well authenticated." In Scott's opinion, "if force of evidence could authorise us to believe facts inconsistent with the general laws of nature, enough might be produced in favour of the existence of the second-sight." All history, all tradition, abounds in instances. A well-known anecdote tells how St Ambrose fell into a comatose state while celebrating the mass at Milan, and on his recovery declared that he had been present at St Martin's funeral at Tours, where, indeed, reports from Tours afterwards declared that he had been seen. A similar experience of Swedenborg's (who described at Gottenburg a fire which was actually raging at Stockholm) is reported by Kant. The wide distribution of the belief is shown by the fact that Mr Mason Browne's exploring party on the Coppermine River was met by Indians, sent by their medicine man, who predicted the coming of the party, just as a seer in the Hebrides described even the livery of Dr Johnson's servant before his arrival. In a remote age and country we find Njal, the hero of the Njal's saga, credited with *forspan*, or the gift of beholding such shadowy apparitions of future events—a power carefully distinguished from ordinary clear-sighted wisdom. Returning to savage life, a complete account of the morbid nature and of the initiation of a diviner is given from the mouths of Kaffir converts in Dr Callaway's *Religion of the Amazulu*. A peculiar organisation, a habit of haunting the desert, and of fasting, combine to produce the *inyanga*, or second-sighted man; what Reichenbach calls *der sensitiv Mensch*, and franker Zulus "a soft-headed one." This part of the subject may be concluded with a quotation from the *Odyssey*, showing the similarity of these prophetic and warning apparitions in the islands of western Greece and of western Scotland. Theoclymenus speaks to the doomed wooers at their latest feast—"Ah, wretched men, what ails you? Your knees, and faces, and heads are swathed in night, and a wailing sound has arisen, and all cheeks are wet with tears, and the walls and the fair spaces of the ceiling do drip with blood, and the porch is full of ghosts, and the court is filled with shadows—the shadows of men bound hellwards—and the sun has perished out of heaven, and an evil mist has overspread the world." Compare Martin in his *Description of the Western Isles*—"When a shroud is perceived about one, it is a prognostick of death. The time is judged according to the height of it about the person; for if it is seen about the middle, death is not to be expected for the space of a year; and as it is frequently seen to ascend higher towards the head, death is concluded to be at hand within a few days or hours, as daily experience confirms." These modern and ancient instances scarcely serve to increase "the force of evidence" that Scott speaks of, but rather to prove that the superstition is a fragment of the most primitive speculations on the facts of trance and coma.

Apparitions in witchcraft. The apparitions which play a part in all the records of trials for witchcraft admit of some explanation, though scarcely an adequate one, in known laws of human nature. It is easy enough to understand how in primitive times the diviner who beheld spirits was also believed to be able to command them to do his bidding and to injure his enemies. The belief persisted under the civilisation of ancient Rome, and Apuleius tells a very impressive story of how the apparition of "a woman of hideous aspect, marked by guilt and extreme sorrow, whose haggard face was sallow as boxwood," was evoked by a witch to slay her foe. No instance of the survival of savage superstitions is stranger than the fact that men like Henry More and Glanvil, Bodin, the great French publicist, Sir Thomas Browne, and Wesley, could still maintain that disease and death might be caused by such malevolent apparitions. We can only say in their defence that the amount of concurrent evidence and confession, corresponding as it did with the prohibition of witchcraft in the Bible, constrained them to share the cruel superstition of their age. Nor is it impossible to assign causes, besides the inadequate one of conscious imposture, for the confessions of the unhappy creatures accused of witchcraft. First we must try to conceive how entirely and implicitly the faith of the middle ages accepted the existence of an omnipresent army of evil spirits. The world was the battlefield of devils and angels, and there was a constant tendency in men's minds to Manichæanism, to crediting the devil with frequent victories. Perhaps no single work enables the modern reader so vividly to imagine this state of terror, this agony of patients who believed that they were in conflict with visible powers of evil, as the autobiography of Guibert de Nogent, the contemporary historian of the first crusade. He has left, in the character of his mother, a most gracious picture of womanly piety, and yet this excellent lady supposed herself to be the nightly prey of Satan, whom she saw in tangible form! Then we must remember that the church everywhere declared that mortals could enter into compact with the fiends; and recalling how subject the middle ages were to imaginary epidemics, fevers of terror and fanaticism, it is not so hard to see how both accusers and accused believed the truth of their charges and confessions. In such an epidemic every one's fancy is inflamed, and people are found to accuse themselves, as they still do when a mysterious murder has excited the morbid brains of foolish persons. At these times we may almost reverse the French proverb, and say *qui s'accuse s'excuse*. Dreadful tortures, too, such as "the most severe and cruel pain of the boots," and "that most strange torment called in Scottish a turkas" (*i.e.*, pincers), want of sleep, and hunger, often made confession and death preferable to life in such misery. But these considerations do not explain away the obvious belief and remorse of many victims, nor account for the similarity in detail of all the confessions.

For the better understanding of these points we may briefly trace the ordinary course of a witch epidemic, as we gather it from the reports in Pitcairn's *Criminal Trials in Scotland*, from the Salem witchcraft trials recorded by Cotton Mather (1692), and from such *procès* as that against Urbain Grandier at Loudun (1632–34), as well as the stories collected by Glanvil in his *Sadducismus Triumphatus*. Generally it happened that some nervous patient, like the girls who used to meet and make what spiritualists now call a circle, in Parris's house at Salem, or the novices who accused Urbain Grandier, or the daughter of Richard Hill of Stoke-Trister in 1664, or Adam Clark of Prestonpans (1607), suffered from some hysterical complaint. In the case of Mistress Hill this malady took the form of stigmata or sudden prickings and swellings of the hands, like those of Louise Lateau, the Belgian ecstatic, whose name has recently become notorious. Living in a Protestant land, Mistress Hill, like all the other patients, referred her sufferings to the machinations of a witch, just as the Australian savage now supposes his ailment to be caused by magic. In the cases we have named, as in most others, the witch was said to appear in visible form, or to send "the devill in likeness of ane blak man efter ane feirfull manner," and so to torment the sufferer. The witch was then charged, examined, tortured, if necessary, in the *witch's bridle* or otherwise, and as a rule confessed, implicating many of her neighbours. The confessions were frequently recanted, like those made under torture by the Templars. They generally ran to the effect that the accused, in a despairing moment, "making heavy fair dule with herself," like poor Bessie Dunlop, who was "convict and brynnt" in 1576, met an apparition. It might be the ghost of Thom Reid who fell at Pinkie fight, or it might be the devil, as in most confessions, or the king of elf-land, but he always offered wealth and happiness in return for the soul of his victim. The bargain was closed, and the witch was taken at night to some spot, often a church, where she met a great number of her neighbours. Here she was made to swear fealty to Satan, who sometimes took the form of a buck in France, or of "a deer or roe" in Scotland. The same revolting ceremonies and travesties of the church service followed as were attributed to the Templars, and the worshippers received power to do evil, raise storms, bewitch cattle, and so on, after which there ensued a licentious revel. Sometimes the witches would fall into trances when under examination, and declare on waking that they had been spiritually present at the joys of the *Sabbat*. Their victims, when confronted with them, frequently became subject to convulsions, and were aware of their presence though walls and doors were between them. Both these facts point to the presence of the phenomena of hypnotism or mesmerism, and the abnormal state produced by concentrated attention and abeyance of the will. The ceremonies of this pretended *Sabbat* can be accounted for if we suppose that the Scotch peasants, like those of France, retained the traditions of those vast nocturnal gatherings, with their revival of pagan rights, their mockery of the church, their unnatural licentiousness, in which the popular misery of the 14th century found relief and expression. An account of these orgies is given in M. Michelet's book *La Sorcière*. He does not appear to have consulted the records of the Scottish trials for witchcraft, which makes the very close resemblance between the Scottish and French confessions even more striking.

In attempting to explain this resemblance, as well as the multitude of well-attested apparitions which the annals of witchcraft report, we have to remember the following facts. The manner of producing these abnormal nervous states, in which the patient is impressed exactly as if he heard and saw what he is commanded to hear and see, has always been familiar to peoples in a low state of civilisation. The witchcraft trials attribute to diabolical influence phenomena which we may now see performed on willing patients by strolling professors of mesmerism and magnetism. The constantly reviving interest in these phenomena, which to-day takes the shape of matter for gossip, in the middle ages swelled into a frenzy of fear and of excited imagination. The church encouraged this fear by its doctrines, and did little to check it by its exorcisms. All classes believed that the power which produces *hypnotism* could be hurtfully exercised, and all classes attempted the impossible crime of slaying by magic. The rural population retained the memory of pagan orgies, of the worship of heathen gods, now declared to be devils; they also retained the harmless tradition of the fairy world, and when tortured into confession they reproduced, with convincing identity, fragments of folk-lore. Isobel Gowdie was burned in Nairn in 1662 for telling tales which would nowadays make her invaluable to the collector of *Märchen* or nursery stories (Pitcairn, iii. 603). Survivals of belief out of an uncivilised stage of progress, attested by the facts of nervous disease, heightened by fear and imagination, interpreted by unscientific theology, go far to constitute the familiar apparitions of witchcraft. It ought to be added that modern believers in spiritualism claim the witches as martyrs of their own faith, and recognise in their reported performances, especially in their power of floating in the air, anticipations of their own puerile miracles.

Ghosts.

The species of apparitions we have discussed may all be traced to the traditions of the non-progressive classes, and connected with the earliest ideas about the supernatural. But the spirits which are most familiar to us, the spectres of ghost stories and fireside tales, rest their claims to existence on the evidence of the eyes and ears of people we meet every day. True, the evidence is of the hearsay class; it is almost as rare to find a witness who has seen a ghost as to encounter a person who does not know some one who has had this experience. As a rule, the deceased friend is said to have appeared at the moment or about the time of his death to an acquaintance at a distance. The belief is now more widely spread and more firmly held among the educated classes than it has been for centuries, and the arguments on both sides are worth consideration. The sceptics do not deny that people have been subjectively affected, in the same way as they would have been if the dead friend had been objectively present. But they bring forward several well-authenticated instances to prove that some people have been subject to *illusory* appearances, of which they could only test the reality by the attempt to handle them. Perhaps the best known case is that of Nicolai, a Berlin bookseller (1790), who repeated his own hallucinations to the academy of Berlin. "They were generally phantasms of his friends and acquaintances; or, in other words, copies of his past impressions and perceptions, so renovated and verified as to create an illusion of reality." Another example is the case of a Mrs A., attested by Sir David Brewster in his *Natural Magic*, and repeated by Professor Huxley in his *Elementary Physiology*. Mrs A.'s illusions were often grotesque and terrible, and she could not always connect them with any past impression. Different philosophical explanations are given of these cases of disordered vision. Dr Hibbert, in his *Philosophy of Apparitions*, conceives that the organs of sense are the actual medium through which past feelings are renovated; or, in other words, that when, from strong mental excitement, ideas have become as vivid as past impressions, or even more so, this intensity is induced by, or rather productive of, an absolute affection of those particular parts of the organic structure on which sensations depend, in the same way precisely as the salivary glands are known to be occasionally as much excited by the idea of some favourite food as if the said body itself were actually present, stimulating the *papillæ* of the *fauces*. It would have been more simple if Dr Hibbert had said that imagination, in some states, reacts upon the organ of sense and renovates past feelings or sensations, the natural antecedents or necessary concomitants of certain perceptions, with an intensity sufficient to create an illusion of reality.

A further explanation is given by Sir David Brewster, who has remarked as a physical fact that, "when the eye is not exposed to the impressions of external objects, or when it is insensible to these objects in consequence of being engrossed with its own operations, any object of mental contemplation, which has either been called up by the memory or created by the imagination, *will be seen as distinctly as if it had been formed from the vision of a real object*. In examining these mental impressions," he adds, "I have found that they follow the motions of the eye-ball exactly like the spectral impressions of luminous objects, and that they resemble them also in their apparent immobility when the eye-ball is displaced by an external force. If this result shall be found generally true by others, it will follow that the objects of mental contemplation *may be seen as distinctly as external objects*, and will occupy *the same local position in the axis of vision* as if they had been formed by the agency of light." This goes to the very root of the theory of apparitions, all the phenomena of which seem to depend upon the relative intensities of the two classes of impressions, and upon the manner of their accidental combination. In perfect health the mind not only possesses a control over its powers, but the impressions of external objects alone occupy its attention, and the play of imagination is consequently checked, except in sleep, when its operations are relatively more feeble and faint. But in the unhealthy state of the mind, when its attention is partly withdrawn from the contemplation of external objects, the impressions of its own creation, or rather reproduction, will either overpower external objects, or combine themselves with the impressions of them, and thus generate illusions which in the one case appear alone, while in the other they are seen projected among those external objects to which the eye-ball is directed, in the manner explained by Dr Brewster. To these physical causes of subjective apparitions, the forces of the imagination, of long desire, of strained attention, are supposed to contribute their influence.

"Enthusiastic feelings of an impressive and solemn nature," says Sir Walter Scott, "occur both in private and public life, which seem to add ocular testimony to an intercourse betwixt earth and the world beyond it. For example, the son who has been lately deprived of his father feels a sudden crisis approach, in which he is anxious to have recourse to his sagacious advice—or a bereaved husband earnestly desires again to behold the form of which the grave has deprived him for ever—or, to use a darker yet very common instance, the wretched man who has dipped his hand in his fellow-creature's blood, is haunted by the apprehension that the phantom of the slain stands by the bedside of his murderer. In all or any of these cases who shall doubt that *imagination*, favoured by circumstances, *has power to summon up to the organ of sight spectres which only exist in the mind of those by whom their apparition seems to be witnessed?* If we add that such a vision may take place in the course of one of those lively dreams in which the patient, except in respect to the single subject of *one* strong impression, is or seems sensible of the real particulars of the scene around him, a state of slumber which often occurs—if he is so far conscious, for example, as to know that he is lying on his own bed, and surrounded by his own familiar furniture, at the time when the supposed apparition is manifested, it becomes almost in vain to argue with the visionary against the reality of his dream, since the spectre, though itself purely fanciful, *is inserted* amidst so many circumstances which he feels must be true beyond the reach of doubt or question. That which is undeniably certain becomes in a manner a warrant for the reality of the appearance to which doubt would have been otherwise attached. And if any event, such as the death of the person dreamt of, *chances to take place*, so as to correspond with the nature and the time of the apparition, *the coincidence*, though one which must be frequent, since our dreams usually refer to the accomplishment of that which haunts our minds when awake, and often presage the most probable events, seems perfect, and the chain of circumstances touching the evidence may not unreasonably be considered as complete."

Now this is the point—namely, the possibility of frequent coincidence—where the advocates of the reality of apparitions join issue with the sceptics. They do not deny that some people have been subject to hallucinations. They say with De Foe, "we have, we believe, as true a notion of the power of imagination as we ought to have. We believe that we form as many apparitions in our fancies as we behold with our eyes, and a great many more. But it does not follow from thence that there are no such things in nature." It is when apparitions of men dying are seen at a distance from the place of their death, or when different witnesses, at different times, behold the same apparition in a certain place, that the explanation of mere fancy or subjective illusion becomes hard to accept. It is unfair of Scott to say that the coincidence between death and distant apparition in dream or waking vision is one which "must frequently happen." Mankind has agreed with Dr Johnson to consider the event *not* fortuitous. Nothing is explained, *if the multitude of such stories are supported by evidence*, by speaking of a coincidence. As Joab says in Voltaire's play, *c'est là le miracle*. Again, to convert Nicolai's visions into genuine apparitions, or to make Mrs A. what Professor Huxley calls a mine of ghost stories, what they saw should have been also seen by others, or should have been followed by some significant event. To give an example of a genuine ghost story as contrasted with a hallucination:—It happened to a lady, a distant relative of the writer, to waken one morning in Edinburgh, and see, as she thought, her father standing by her side. He was dressed in his full uniform as a general in the East India Company's army, and seemed to her to press his hand on his side with a look of pain, and then to disappear. The lady mentioned what she supposed she had seen to the clergyman with whom she was residing. He took a note of the date of the occurrence, which happened in a time, as was supposed, of profound peace. The next news from India brought tidings of the mutiny, and that the lady's father had gone out in full uniform to address his native troops, and had been shot down by them. Now granting, for the sake of argument, that the evidence for this story is sufficient, believers in apparitions would be justified in saying that a coincidence so odd must have some unexplained cause. Two explanations of appearances of this kind suggest themselves to the savage and the scientific spiritualist respectively. The former believes that all real objects have their shadowy doubles in the next world; the weapons buried with the dead chief send their doubles to join him in the happy hunting-grounds. The latter holds that the seer is subjectively affected in the manner desired by the person whose apparition he beholds, who naturally assumes some familiar raiment, "his habit as he lived." To take another example. The writer once met, as he believed, a well-known and learned member of an English university who was really dying at a place more than a hundred miles distant from that in which he was seen. Supposing, for the sake of argument, that the writer did not mistake some other individual for the extremely noticeable person whom he seemed to see, the coincidence between the subjective impression and the death of the learned professor is, to say the least, curious. Pursuing this line of thought, the whole question becomes one of evidence. Does the number of well-attested coincidences between the time of death and the moment of apparition exceed the limits that the laws of chance allow? Till people who have seen such spectres can give up the habit of adorning their stories with fanciful additions, and can make up their minds to attest them with their names, the balance of argument is on the side of the sceptics. These reasoners seem, however, to lay too much stress on the effect of "expectant attention." It is *not* as a rule the anxious mourner who beholds the spectre of the beloved dead. No sorrow is more common than the affliction of Margaret as described by Wordsworth:—

> "'Tis falsely said
> That there was ever intercourse
> Betwixt the living and the dead,
> For surely then I should have sight
> Of him I wait for day and night
> With love and longings infinite."

It may be added that hallucinations, or whatever we are to call the impression of beholding objects of supernatural horror, are not confined to the human race. A remarkable example of superstitious horror shown by a dog, at the moment of a supposed apparition to his owner, is given in the *Edinburgh Medical and Surgical Journal*, vol. lxiv., pp. 186–187. In the same way, during the mysterious disturbances at the house of the Wesleys, "the mastiff was more afraid than any of the children." Popular superstition has used this belief. When the dogs howl, in the Danish ballad, or in its Provençal counterpart, the cruel stepmother is afraid of the apparition of the dead mother, and treats the children kindly. In the same way, when Athene, in the *Odyssey*, appears to Odysseus, Telemachus cannot see her, but the dogs crouch and whine in fear. The case of Balaam's ass is sufficiently well known.

Spiritualism. The latest and the most important development of the belief in apparitions is that known as spiritualism. The believers in a religion based on pretended communications from the dead are numbered in America by millions. Their opponents say that their faith and practice help to fill the lunatic asylums, to which they easily reply that theirs is not the only creed that gives occasion to religious madness. Men of sense and experience are numbered in their ranks, and even in England it would be easy to name persons of eminence in art and literature, and some branches of science, who are puzzled by the phenomena they suppose themselves to have witnessed. Thus the late Augustus de Morgan writes in the preface of *From Matter to Spirit* —"I am perfectly convinced, in a manner which should make unbelief impossible, that I have seen things called spiritual which cannot be taken by a rational being to be capable of explanation by imposture, coincidence, or mistake."

Modern spiritualism arose from one of the commonest superstitions in the world—the belief in haunted houses. What the Germans call the *Poltergeist* (the noisy spirit that raps and throws about furniture) is not peculiar to any country. We find it in Japan (see *Tales of Old Japan*), in Russia, in Egypt. Pliny tells of the haunted house of Athenodorus, the philosopher, in Athens. In Iceland the ghost of the dead thrall Glam raps on the roofs in the Gretti's saga; and "the Dyaks, Singhalese, and Siamese agree with the Esths as to such routing and rapping being caused by spirits." Such disturbances, accompanied with apparitions, haunted the house inhabited by Mrs Ricketts, a sister of Earl St Vincent. Scott says in reference to this case that "no one has seen an authentic account from the earl;" but his sister's report has recently been published (see the *Gentleman's Magazine* for May 1872). Every one has heard of the rappings in the house of the elder Wesley. Glanvil, in his *Sadducismus Triumphatus*, has left well-authenticated reports of many cases, notably that of the drummer of Tedworth. The house of Mr Mompesson of Tedworth, in 1651, was disturbed by continual noises—furniture moving of its own accord, *raps that could be guided by raps given by the spectators*. Precisely the same phenomena occurred in the house of a Mr Fox, in West New York, in 1847–48. It was discovered by his daughter, Miss Kate Fox, a child of nine years old, that the raps replied to hers. An alphabet was then brought, the raps spelled out words by knocking when certain letters were pointed to, and modern spiritualism was born. It has again and again attracted notice in England; medium after medium has crossed the Atlantic; impostures have been exposed and defended; and opinion continues to be divided on the subject. The views of a believer, though not a fanatical one, may be quoted from Mr Dale Owen's book, *The Debatable Land*:—

"1. There exists in the presence of certain sensitives of highly nervous organisation a mysterious force, capable of moving ponderable bodies, and which exhibits intelligence. Temporary formations, material in structure and cognisable by the senses, are produced by the same influence—for example, hands which grasp with living power.

"2. This force and the resulting phenomena are developed in a greater or less degree according to the conditions of the sensitive, and in a measure by atmospherical conditions.

"3. The intelligence which governs this force is independent of, and external to, the minds of the investigator and of the medium. For example, questions unknown to either (*sic*), and in language unknown to either, are duly answered.

"4. The origin of these phenomena is an open question."

Now, as a rule, these phenomena are exhibited in the presence of "sensitives," who are paid for exercising their profession, and who prefer to do so in a dark room. Men of science who have attended these exhibitions have not always met with interesting results, and the conclusions at which some of them have arrived may be stated thus:—

1. As a rule, nothing worth notice has occurred at *séances* where competent observers have been present. Spiritualists reply that the spiritual kingdom can only be entered after long and patient attendance at many *séances*, and that the presence of the sceptic destroys the force of the spiritual influences.

2. When strange phenomena have been witnessed, they have often been traced to conscious imposture and *legor*

demain. Believers answer with sorrow that imposture is only too common on the part of mediums diffident of their powers; but the aim of science ought to be to detect the realities that co-exist with the imposture.

3. Where conscious imposture does not come in, *unconscious cerebration* and *unconscious muscular action*, supervening on a state of *expectant attention*, are just as deceitful. That the mediums are in a morbid condition is proved by the feeling of a cold air passing over the hands, like the *aura epileptica.* Unconscious muscular action may be defined as the involuntary response made by the muscles to ideas with which the mind may be possessed when the directing power of the mind is in abeyance. The response given by rapping on the part of the agitated furniture is due to unconscious cerebration—that is, to ideational changes taking place in the cerebrum—of which we may be at the time unconscious through a want of receptivity on the part of the sensorium. The answer given, though not present in conscious thought, may exist in latent thought, and that latent thought may stimulate muscular action towards producing the unconsciously-desired result. In their reply, spiritualists depend on evidence which science hesitates to accept. They say that they have seen such phenomena as no *consciously* exerted muscular power could produce, and heard replies that did not exist even in their *latent* consciousness. Hence they insist on the presence of "a new force."

4. The received spiritualist theory belongs to the philosophy of savages. A savage looking on at a spiritual *séance* in London would be perfectly at home in the proceedings. It is answered that the savage's evidence and belief is an undesigned coincidence of great confirmatory strength.

5. The reported doings and sayings of the spirits are trivial, irreverent, useless, and shocking. Spiritualists reply, with Swedenborg, that death works no immediate change in character or knowledge, and agree with Plato, in the *Phædo*, that the lowest and idlest souls are precisely the most likely to revisit earth. But with perseverance they look for better things.

We must leave the question *sub judice.* No one can be surprised that men of science hold back from devoting valuable time to the investigation of phenomena associated with darkened rooms, hysterics, and confessed imposture. On the other hand, believers will insist on crediting their eyes and ears, and being influenced by hopes and love and fears. Apparitions must be allowed to be an exception to the general ordinance—a disturbing influence in the healthy tide of things. It is more probable that the ordinary laws of nature will hold their sway than that a revolution is about to be effected in all human and divine relations. This is what spiritualists expect, and their attitude has its interest for the student of Man. Perhaps the principal lesson to be gained from the study of the theories of apparitions is that human nature remains essentially the same, beneath the shifting surface of creeds and customs.[1] (A. L.)

APPEAL, in its usual modern sense, is the act by which a decision is brought for review from an inferior to a superior court. In Roman jurisprudence it was used in this and in other significations; it was sometimes equivalent to prosecution, or the calling up of an accused person before a tribunal where the accuser appealed to the protection of the magistrate against injustice or oppression. The derivation from the word *appello,* naturally shows its earliest meaning to have been an urgent outcry or prayer against injustice. Hence it inferred a superior power capable of protecting against petty tyranny. In its meaning of seeking a higher tribunal for recourse against a lower, it does not seem to have been a characteristic of the Republic, where the magistrate was generally supreme within his sphere, and those who felt themselves outraged by injustice threw themselves on popular protection by *provocatio,* instead of looking to redress from a higher official authority. The Empire, however, introduced grades of jurdisdiction, and the ultimate remedy was an appeal to the emperor; thus Paul, when brought before Festus, appealed unto Cæsar. It must be understood that the appeal was actually dealt with by a supreme judge representing the emperor, not by the emperor in person. In the Corpus Juris, the appeal to the emperor is called indiscriminately *appellatio* and *provocatio.* A considerable portion of the 49th book of the Pandects is devoted to appeals; but little of the practical operation of the system is to be deduced from the propositions there brought together.

The ecclesiastical hierarchy, and the gradations of the feudal system, naturally afforded scope in the Middle Ages for appeals from the lower to the higher authority. In matters ecclesiastical, including these matrimonial, testamentary, and other departments which the church ever tried to bring within the operation of the canon law, there were various grades of appeal, ending with the Pope. The European princes in general struggled against this assumption of authority by the court of Rome, and it was the source of many contests between the ecclesiastical and the regal power.

It became customary for ambitious sovereigns to encourage appeals from the courts of the crown vassals to themselves as represented by the supreme judges, and Charlemagne usually enjoys the credit of having set the example of this system of centralisation, by establishing *missi dominici.* The great vassals, however, sought recourse against the decisions of the royal courts in their own order, embodied as the great council or parliament of the nation, and hence arose the appeal to the House of Lords as the court of last resort.

When the progress of civilisation and the art of self-government render judges no longer amenable to the charge of tyranny or fraud, an appellate system changes its character and objects. It in some measure certainly tends to preserve that judicial integrity which renders it unnecessary as the immediate refuge of the persecuted suitor. But its ostensible object is the preservation of uniformity in the law. The attainment of this object renders it unfortunately necessary, in such a country as ours, that no tribunal shall give, in the first instance, in any important question, a decision which is not open to appeal. The process has the double advantage, that it has a tendency to bring every legal difficulty ultimately to one tribunal, where a uniformity of principle may be expected in the application of the law, and, at the same time, stimulates the exertions of the subordinate judge, who knowing that his proceedings will be revised, is careful to bring them as close as he can to those uniform principles of law, which he knows that the court of appeal

---

[1] The most eminent defender of modern spiritualism, Mr Alfred Wallace, reports a novel kind of apparition in the *Fortnightly Review* for May 1874. It seems that a young lady medium has the power of sending a semblance of herself into one room, while she is bound hand and foot in another. The pleasing peculiarity of this apparition is that *it* is no mere shadow, like the mother of Odysseus, whom he could not embrace in Hades. Mr Crookes, a Fellow of the Royal Society, has inspected it with a phosphorus lamp, and clasped it in his arms within the medium's sight. In M. Gautier's romance *Spirite*, the lover was not permitted to touch his airy mistress. Truth is indeed stranger than fiction.

will apply. To accomplish this function of an appellate system, it is right that the investigation of the question at issue should have been exhausted in the inferior court, and that the court of appeal should have nothing before it which has not been there considered; for if the inferior court decide on one representation of circumstances, and the court of appeal on another, the public will lose the advantage of having the principle which was applied in the inferior reversed or affirmed in the superior tribunal.

The House of Lords has hitherto been a court of appeal from the chief civil courts in the United Kingdom. The origin of the appellate jurisdiction of the House of Lords was undoubtedly of that partly feudal and partly popular character already alluded to, which made the suitor seek justice from the high court of Parliament, when it was refused in the baronial court, or even by the king's judges. Hence the lords exercised the mixed function of jurymen and judges, and, as in judgments on impeachment, the house might be influenced by private or party considerations, debating and dividing on the question before them. A revolution was silently accomplished, however, by which the function of reviewing the decisions of the courts fell entirely to the lawyers raised to the peerage, or to other judges brought in to give their aid; and the unprofessional lords only attended to give the sanction of a quorum to the proceedings. The letters and memoirs, so late as Queen Anne's reign, show that party or personal influence and persuasion were employed to procure votes on appeals, as they have in later times on railway or other local bills. The last instance probably in which a strong division of opinion was manifested among the unprofessional lords was the celebrated Douglas cause in 1769, when the house was addressed by the dukes of Newcastle and Bedford, but was led by the authoritative opinion of Lord Mansfield on the effect of the evidence,—an opinion which, being treated rather as that of a political partisan than of a judge, was sharply commented on in a work of great ability written by Mr James Stuart, who had a deep personal interest in the cause. The case of O'Connell and others, brought up on writ of error from the Queen's Bench in Ireland, in 1844, may be said to have finally established the precedent, that the judgments of the House of Lords were to be given solely by the law lords. On that occasion there was a difference of opinion among the law lords themselves. The judgment of the majority was strongly against the political feeling of the Government and of the peers as a body, while the law lords who carried the decision had been appointed by previous Governments opposed in politics to the existing cabinet. But all these temptations to a party vote by the unprofessional members were resisted. It has been the constant practice of the House, in cases of difficulty, to consult the judges of the inferior courts, and the decision of the House is usually determined by their opinion.

Of old, in Scotland, there was something anomalous in an appeal to Parliament, as the Court of Session was in its original constitution a committee of Parliament, for the performance of its judicial functions. In the reign of Charles II., however, the courts grew so intolerably corrupt that a determined effort was made to have their judgments overturned, by an appeal which was strictly of the old character of a cry for protection against flagrant injustice. It was called a "protest for remeid of law," and was inserted as one of the national claims in the Petition of Right at the Revolution. There was no allusion to an appeal system in the Treaty of Union; but the House of Lords, when appealed to against the judgments of the Court of Session, acted without hesitation. Many attempts were made, but without effect, to carry appeals from the supreme criminal courts in Scotland to the House of Lords.

The appeal system of this country previous to the Judicature Act of 1873 was constituted in the following manner. The House of Lords sat during the parliamentary session to hear appeals from the superior Courts of Equity and Common Law, from the corresponding courts in Ireland, and from the Court of Session in Scotland. In none of these cases, however, was the appeal directly from the judge of first instance to the final court. In the Common Law Courts, an appeal, under the name of a writ of error, was given from the decision of any one of the Common Law Courts to the decision of members of the other two, sitting in what was called the Court of Exchequer Chamber, and from that court to the House of Lords. In Equity the decisions of the Vice-Chancellors were subject to review before an appeal court, composed of the Lord Chancellor and two Lords Justices of appeal. The same procedure was observed in Ireland. In Scotland the appeal began by a reclaiming note from the Lord Ordinary to one of the divisions of the Court of Session, from which it passed to the House of Lords. The Judicial Committee of the Privy Council served as a court of final appeal for admiralty, ecclesiastical, and colonial cases. Established in 1833 to hear complaints by way of appeal addressed to her Majesty in Council, it was reconstituted in 1851, and again in 1870. At first it was a court composed entirely of *ex officio* judges, but in 1870 four paid judges were appointed—the composition of the court being varied from time to time by the addition of other members specially qualified to consider the special cases in hand. Thus, in ecclesiastical appeals the attendance of certain qualified prelates was provided for. The inconvenience of having two independent courts of final appeal, the unsatisfactory character of the intermediate process, and the uncertain composition of the appeal court in the House of Lords, were among the chief considerations which suggested the recent judicature reform. By the 36 and 37 Vict. c. 66, the several supreme courts are united and consolidated together under the name of the Supreme Court of Judicature in England. The Supreme Court is divided into two great tribunals, the first of which is called the High Court of Justice, and the second the Court of Appeal. The latter is invested with all the powers of the superior appeal courts previously existing, but it may be briefly described as a court of appeal from the High Court of Justice. Power is given to her Majesty to transfer by order all appeals and petitions which ought to be heard by the Judicial Committee of the Privy Council to the Court of Appeal. In ecclesiastical cases it is provided that the Court of Appeal "shall be constituted of such, and so many judges thereof, and shall be assisted by such assessors, being archbishops or bishops of the Church of England," as her Majesty, by any general rule, may think fit to direct. Appeals from inferior tribunals (County Courts, Petty, or Quarter Sessions) are to be determined by the divisional courts of the High Court of Justice, and no further appeal is possible unless by special leave of the divisional court. Appeals may be heard either by the full court of appeal, or by divisional courts thereof, consisting of not less than three judges, and any number of such courts may sit at the same time. The Court of Appeal shall consist of five *ex officio* and not more than nine ordinary judges; her Majesty may also appoint as additional judges, from time to time, persons who have held certain high judicial offices in the United Kingdom or in India. The Lord Chancellor is President of the Court of Appeal, and the ordinary or additional judges are to be styled Lords Justices of Appeal.

The Judicature Act of 1873 made no provision for transferring the Scotch and Irish business of the House of Lords to the new Appeal Court, and it is worthy of mention that a successful motion to that effect in the House of

Commons was treated by the other house as a breach of its privileges, and was finally abandoned. The Amendment Bill of 1874 (withdrawn for want of time at the close of the session) supplied this deficiency, and made some changes in the divisional arrangements of the Appeal Court. Although under the Act of 1873 there was nominally only one appeal, yet as the court was to sit in division, it was feared that there might be some danger of these divisions gradually developing independent and contradictory principles of jurisprudence. It was therefore proposed that one division of the Appellate Court should sit to hear Scotch and Irish and important colonial cases, the rest of the court sitting in sections according to convenience. Should there be a disagreement of opinion among the judges of these lower sections, a rehearing before the first division was to be permitted.

The large proportional amount of the judicial work in the House of Lords, caused by appeals from Scotland, has often been noticed. It proceeds from two causes. In England there was a virtual appeal for writ of error from one of Common Law Courts to the other two, not exemplified in Scotland. But there have always appeared to the disappointed Scotch litigant chances in his favour from his appealing to English judges against the Scotch judges who have decided against him; and the House of Lords being not only a court of law, but a House of Parliament, was believed to be at liberty to take wider views of legal questions than the constitution permitted to the inferior courts. Under the new system, proposed in the Bill of 1874, appeals for Scotland will only be allowed when the cause involves money to the amount of £500, or points of law relating to the right of property. It may be doubted whether the principle of such restriction can in any case be defended, and it is clear that the limit fixed by the bill would exclude many causes of great commercial importance. No express provision is made for the presence of a Scotch judge in the Court of Appeal, but Scotch advocates and judges are to be eligible for appointments to that tribunal, and there would probably always be one, at least, of its members selected for his acquaintance with the law of Scotland.

In France the adoption of the nomenclature of the civil law has made the term, in its French shape of *appel*, of more comprehensive use to express references from a lower to a higher tribunal, than in this country.

The United States, in adopting the structure of the English law, brought with it the practice of appeal and writ of error, but the federal constitution and the jealousy of central power have practically restricted the operation of the system. By the constitution, the Supreme Court of the United States is vested with "appellate jurisdiction, both as to law and fact, with such exceptions, and under such regulations, as Congress should make." It appears to have been held, however, that this does not confer appellate jurisdiction, but only authorises Congress to create it. In the words of Mr Kent, "If Congress had not provided any rule to regulate the proceedings in appeal, the court could not exercise an appellate jurisdiction: and, if a rule be provided, the Court could not depart from it. In pursuance of this principle, the Court decided in *Clarke* v. *Bazadone*, that a writ of error did not lie to that court from a court of the United States territory northwest of the Ohio, because the act had not authorised an appeal or writ of error from such a court."—(*Commentaries*, i. 324.) It was urged that the constitution itself had vested appellate jurisdiction in the Supreme Court, but that Congress may introduce such exceptions as it thinks proper. The action of Congress, it was said, is not required to create the jurisdiction, but is sufficient at any time to remove any part of it. The Court, however, has adhered to the view that its appellate jurisdiction is limited by the judiciary statutes, which are to be understood as making exceptions, and implying a negative on the exercise of such power in every case but those in which it is affirmatively given.

A peculiar and pernicious process which existed until a late period in English criminal law, received the name of appeal. It was a right of prosecution possessed as a personal privilege by an injured party, of which the Crown could not deprive him, directly or indirectly, since he could use it alike when the prisoner was tried and acquitted and when he was convicted and pardoned. It was chiefly known in practice as the privilege of the nearest relation of a murdered person, and was generally employed when the public passions were roused against the accused, on account, not so much of the evidence against him as the atrocity of the crime. Thus, after Colonel Oglethorpe's inquiry and report on the London prisons, when, in 1729, Banbridge and the other jailors were acquitted on indictments for deficiency of evidence, they were hotly pursued by appeals of murder. In the case of Slaughterford, in 1708, the public indignation was roused by the atrocity with which the accused was charged with murdering the woman he had seduced. The evidence was very imperfect, and he was acquitted on indictment; but an appeal was brought, and on conviction he was hanged, as his execution was a privilege belonging to the prosecutor of which the Crown could not deprive him by a pardon. In 1818 a parallel case occurred, when the appeal was ingeniously met by an offer of battle, since if the appellee were an able-bodied man, he had the choice of the two ordeals, combat or a jury. This neutralising of one obsolete and barbarous process by another, called the attention of the Legislature to the subject, and appeal in criminal cases, along with trial by battle, was abolished by 59th Geo. III., cap. 46.

APPENDINI, Francesco Maria, historian and philologist, was born at Poirino, near Turin, on the 4th Nov. 1768. Educated at Rome, he took orders and was sent to Ragusa, where he was appointed professor of rhetoric. When the French seized Ragusa, Napoleon placed Appendini at the head of the Ragusan Academy. After the Austrian occupation he was appointed principal of the Normal Institution at Zara, where he died in 1837. Appendini's chief work was his *Notizie Istorico-critiche sulle Antichità, Storia, e Letteratura dei Ragusei* (1802–3).

APPENZELL (for derivation see below), one of the twenty-two cantons of the Swiss Confederation, is an alpine region, with an area of about 152 square miles, entirely surrounded by the canton of St Gall. The mountains in the south attain a considerable elevation, the highest, Mount Sentis, being 8215 feet in height, and reaching the region of perpetual snow; but towards the north the surface is composed of mere hills and hollows, some of the hills being rather remarkable for their conical shape. The canton is watered by a tributary of the Thur, the Sitter, which takes its rise from a glacier on Mount Sentis, its affluent the Urnäsch, and a number of mountain streams. It was at one time almost covered with forests of fir and pine; but in consequence of the extension of the population, these have been greatly diminished. Peat and wood for fuel are abundant. The climate is cold and variable, but not unhealthy. Subject like the rest of Switzerland to the Franks in the 8th century, Appenzell gradually passed into the hands of the abbots of St Gall; in 1401 it rebelled against what had become an ecclesiastical tyranny; and in 1513 it was admitted into the Swiss Confederation. The violent struggles which followed the Reformation led to its division, in 1597, into two parts—the Inner Rhodes (a word of military origin, like the German *Rotte*), in the south, being appropriated to the Roman Catholics, and the Outer Rhodes, in the north, to the Protestants. This distinction has continued to the present day; the census of 1870 giving the number of Protestants in the Catholic district as only 188, and of Catholics in the Protestant, 2358. Until 1848, indeed, no Protestants, or even Catholic aliens, were allowed to settle in Inner Rhodes. The chief town of that division is Appenzell, and of the other, Trogen. Each district has its own democratical constitution, consisting of a *Landesgemeinde*, or General Assembly, where every freeman above 18 years is bound to appear, and a Great Council, chosen by the people, the members of which must submit their acts to the general approval for their ratification. Outer Rhodes sends two members to the *Nationalrath*, or House of Representatives of the Confederation, and Inner Rhodes one, besides the two members which the canton sends to the *Standerath*, or Senate. Appenzell has taken the civil code of Zurich for its model, and has instituted a court of appeal. The value of real and other property in Outer Rhodes is estimated at £59,028, and in Inner Rhodes at £9600; the revenue of Outer Rhodes at £12,699, and its expenditure, £12,800 (1868); and the revenue of Inner Rhodes at £6031, and its expenditure at £6011. In 1837 the population of the canton was 50,876; in 1860, 60,624, of whom 48,604 belonged to the Protestant division; and in 1870, 60,635, of whom 48,726 belonged to Outer Rhodes. This division, therefore, is far more populous and wealthy than the other part of the canton. Its inhabitants are industrious, and carry on large manufactures of cotton and linen goods and embroidery, while the inhabitants of Inner Rhodes are chiefly engaged in the rearing of cattle and the making of cheese. Since railway communication has made the district more accessible, a great number of strangers come to take advantage of the whey-cure establishments at Gais, Weissbad, Gonten, Urnäsch, &c. A peculiar dialect—differing from the ordinary Swiss German—is spoken throughout the canton. Red is the prevailing colour in the national dress; and athletic sports and rifle-shooting are the favourite amusements.

APPENZELL, the chief town of Inner Rhodes, in the canton of Appenzell, derives its name (*Abbatis Cella*, *Abtenzelle*), like Bischofszell and St Peterzell in the same region, from its ancient ecclesiastical connection. It is situated in the beautiful valley of the Sitter, and has a church with an old Gothic choir, two convents, and a council-house. The *Landesgemeinde* holds its meetings in the open square. In the *Archiv* are preserved a number of ancient banners, and among them one captured from the Tyrolese, with the grotesque inscription, *Hundert Tausend Teufel*. The inhabitants, who are almost entirely Roman Catholics, are largely employed in the production of embroidery, and number about 3700.

APPERLEY, CHARLES JAMES, a sportsman and sporting writer, better known as "Nimrod," the *nom de plume* under which he published his works on the chase and the turf, was born at Plasgronow, near Wrexham, in Denbighshire, in 1777. During the period of his education at Rugby he paid more attention to field-sports than to classics; and between the years 1805 and 1820 he devoted himself almost wholly to fox-hunting, so that he was by early training well fitted for the position of authority he afterwards acquired in the sporting world. About 1821 he began to contribute to the *Sporting Magazine*, under the pseudonym of "Nimrod," a series of articles, which from their racy character did the magazine admirable service. Its circulation doubled within two years; and the proprietor, Mr Pittman, with great liberality, kept for "Nimrod" a stud of hunters, and defrayed all expenses of his tours, besides giving him a handsome salary. The death of Mr Pittman, however, led to a law-suit with the proprietors of the magazine for money advanced to "Nimrod;" and the latter, to avoid imprisonment, had to take up his residence near Calais (1830), where he supported himself by his writings. He died in London, 19th May 1843. The most important of his works are—(1.) *Remarks on the Condition of Hunters, the Choice of Horses*, &c., Lond. 8vo, 1831; (2.) *The Chase, the Turf, and the Road* (originally written for the Quarterly Review), Lond. 1837; (3.) *Memoirs of the Life of the late John Mytton*, Lond. 1837; (4.) *Nimrod's Northern Tour*, Lond. 1838; (5.) *Nimrod Abroad*, 2 vols. 12mo. Lond. 1842; (6.) *The Horse and the Hound* (a reprint from the seventh edition of the *Encyclopædia Britannica*), 1842; (7.) *Hunting Reminiscences*, Lond. 1843.

APPIA VIA, the most celebrated of the ancient Roman roads, connecting the capital with Brundusium. It was commenced by Appius Claudius Cæcus (312 B.C.), who carried it from the Porta Capena to Capua (Livy, ix. 29). Its extension to Beneventum, and ultimately to Brundusium, making its total length about 350 miles, was completed before 30 B.C. The pavement, which rested upon several prepared substrata, was formed by large blocks of hard stone (*silex*) fitted to each other with great exactness. Its breadth was from 14 to 18 feet, excluding the footpaths. The course of the Appian Way is described by Horace, and Statius calls it the Queen of Roads (*Regina Viarum*). From a statement in Procopinus, it appears that the road was in perfect repair in his time (500–565).

APPIAN, an eminent writer of Roman history in Greek under the reigns of Trajan and Adrian. He was a native of Alexandria in Egypt, whence he went to Rome, where he became a distinguished advocate, and was chosen one of the procurators of the empire. He did not treat of the history of the Roman empire as a whole, but gave separate accounts of the various provinces as they were attached to the empire. Of his voluminous work there remains only what treats of the Punic, Syrian, Mithridatic, and Spanish wars, with those against Hannibal, the civil wars, and the wars in Illyricum, and some fragments of the Celtic and Gallic wars,—in all about one-half of the original twenty-two books. An excellent edition of Appian was published by Schweighäuser at Leipsic, in 1785, 3 vols. 8vo, in which the extracts from the lost books are collected. The best edition of the text is that of Bekker, 1853.

APPIANI, ANDREA, the best fresco painter of his age, born at Milan in 1754, died in 1817. He was made pensioned artist to the kingdom of Italy by Napoleon; but having lost his allowance after the events of 1814, he fell into poverty. Correggio was his model, and his best pieces, which are in the church of the Virgin and the royal palace of Milan, almost rival those of his great master. He is also said to have painted Napoleon and the chief personages of his court. Among the most graceful of his oil paintings are his "Venus and Love," and "Orlando in the garden of Armida."

APPIUS CLAUDIUS. See CLAUDIUS.

APPLE. The apple (*Pomme*, Fr.; *Apfel*, Ger.) is the fruit of *Pyrus Malus*, belonging to the Sub-order *Pomaceæ*, of the Natural Order *Rosaceæ*. It is one of the most widely cultivated, and best known and appreciated of fruits belonging to temperate climates. In its wild state it is known as the crab-apple, and is found generally distributed throughout Europe and Western Asia, growing in as high a latitude as Drontheim in Norway. The crabs of Siberia belong to a different species, and are named *Pyrus baccata* and *P. prunifolia*. The apple-tree as cultivated is a moderate sized tree with spreading branches, ovate, acutely serrated or crenated leaves, and flowers in corymbs. The fruit is too well known to need any description of its external characteristics. The apple is successfully cultivated in higher latitudes than any other fruit tree, growing up to 65° N., but notwithstanding this, its blossoms are more susceptible of injury from frost than the flowers of the peach or apricot. It comes into flower much later than these trees, and so avoids the night frost which would be fatal to its fruit bearing. The apples which are grown in northern regions are, however, small, hard, and crabbed, the best fruit being produced in hot summer climates, such as Canada and the United States. Besides in Europe and America, the fruit is now cultivated at the Cape of Good Hope, in Northern India and China, and in Australia and New Zealand.

Apples have been cultivated in Great Britain probably since the period of the Roman occupation, but the names of many varieties indicate a French or Dutch origin of much later date. In 1688 Ray enumerated 78 varieties in cultivation in the neighbourhood of London, and now it is calculated that about 2000 kinds can be distinguished. According to the purposes for which they are suitable, they can be classed as—1st, dessert; 2d, culinary; and 3d, cider apples. The principal dessert apples are the Pippins (*pepins*, seedlings), of which there are numerous varieties. The most esteemed of all apples is the American Newtown Pippin, a globular, juicy, sweet, and highly aromatic fruit; other American varieties of note are Williams's Favourite, Astrakhan, and Gravenstein, and for winter use the Baldwin, Spitzenberg, and Roxbury Russet. As culinary apples, besides Rennets and other dessert kinds, Codlins, and Biffins are cultivated. In England, Herefordshire and Devonshire are famous for the cultivation of apples, and in these counties the manufacture of cider is an important industry. Cider is also extensively prepared in Normandy and in Holland. Verjuice is the fermented juice of crab apples.

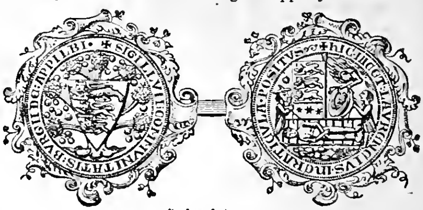
Apples for table use should have a sweet juicy pulp and rich aromatic flavour, while those suitable for cooking should possess the property of forming a uniform soft pulpy mass when boiled or baked. In their uncooked state they are not very digestible, but when cooked they form a very safe and useful food, exercising a gentle laxative influence. According to Fresenius their composition is as follows:—

Apple.	Water.	Sugar.	Free acid.	Albuminous substances. &c.	Salts.
English Rennets, ...	82·04	6·83	0·85	7·92	0·36
White Dessert, ...	85·04	7·58	1·04	2·94	0·44
English Golden Pippin,	81·87	10·36	0·48	5·11	

A large trade in the importation of apples is carried on in Britain, the amount of which is not, however, separately stated in the Board of Trade returns. Our imports come chiefly from French, Belgian, and Dutch growers, and from the United States and British North America. Dried and pressed apples are imported from France for stewing, under the name of Normandy Pippins, and similarly prepared fruits come also from America.

Many exotic fruits, having nothing in common with the apple, are known by that name, *e.g.*, the Balsam apple, *Momordica balsamina*; the Custard apple, *Anona reticulata*; the Egg apple, *Solanum esculentum*; the Rose apple, various species of *Eugenia*; the Pine apple, *Ananassa sativa*; the Star apple, *Chrysophyllum Cainito*; and the apples of Sodom, *Solanum sodomeum*.

APPLEBY, a market and borough town of England, capital of Westmoreland, situated on the Eden, 13 miles S.E. of Penrith. The greater part of Appleby, consisting of a broad, irregularly built street, from which smaller ones branch off, occupies the slope of a hill on the left bank of the river, in the parish of Appleby St Lawrence; but on the opposite bank, in the parish of Appleby St Michael, is the suburb of Bongate, which is connected with the rest of the town by a fine old stone bridge. Appleby contains an



Seal and Arms.

ancient castle, two parish churches, as well as Wesleyan places of worship, a town and a county hall, a jail, an hospital for thirteen poor women, and a grammar school. There is a municipal corporation, and previous to the Reform Act of 1832 the town returned two members to parliament. It has for a long time been a place of small importance, with little trade, and hardly any manufactures. Population of the Improvement Commissioners' District in 1871, 1989.

APPRAISER (from *ad* and *pretium*, value), one who sets a value upon property, real or personal. By 46 George III. c. 43, appraisers must possess a license, the duty payable for which is at present £2 annually. By a statute of William and Mary, two sworn appraisers must be employed by the sheriff to value any goods taken under distress for rent. The business of appraiser is usually combined with that of auctioneer.

APPRENTICE—APPRENTICESHIP. Apprenticeship (from *apprendre*, to learn) is a contract whereby one person, called the master, binds himself to teach, and another, called the apprentice, undertakes to learn some trade or profession, and to serve his master for a certain time. The contract is generally created by indenture, but any writing properly expressed and attested will suffice.

The *Civilians* are silent on the subject of this contract, nor does it seem to have had any connection with the division of the Roman citizens into tribes or colleges. So far as can be seen it arose in the Middle Ages, and formed an integral part of the system of guilds and corporations by which skilled labourers of all kinds sought protection against the feudal lords, and the maintenance of those exclusive privileges with which in the interests of the public they were favoured. In those times it was believed that the arts and sciences would not flourish unless such only were allowed to practise them as had given proofs of reasonable proficiency and were formed into bodies corporate, with certain powers of self-government and the exclusive monopoly of their respective arts within certain localities.

It has sometimes been supposed that these mediæval corporations were confined to such occupations as are now followed by artisans. This, however, is a mistake. The word *universitas* is the correct Latin name for any corporation whatsoever; and in mediæval parlance it was just as proper to speak of the university of smiths or tailors, as of the university of Paris or Oxford. It is, indeed, very probable that, at the dawn of returning civilisation, the humbler arts first received the attention and the fostering care of the state; but it is certain that as each lost art or science was recovered, its professors were formed into a university or corporation, composed of such as were entitled to practise and teach, and such as were in course of learning. The former were the masters, the latter the apprentices. Hence the term *Apprentice* was applied indifferently to such as were being taught a trade or a learned profession, and even to undergraduates or scholars who were qualifying themselves for the degree of doctor or master in the liberal arts. When barristers were first appointed by Edward I. of England, they were styled *apprenticii ad legem*—the serjeants being *servientes ad legem*; and these two terms corresponded respectively to the trade names of apprentices and journeymen. During the middle ages the term of apprenticeship was seven years, and this period was thought no more than sufficient to instruct the learner in his profession, craft, or mystery, under a properly qualified master, teacher, or doctor—for these names were synonymous—and to reimburse the latter by service for the training received. After this the apprentice became himself a master and a member of the corporation, with full rights to practise the business, and to teach others in his turn; so also it would seem that undergraduates had to pass through a curriculum of seven years before they could attain the degree of doctors or masters in the liberal arts. On the Continent of Europe these rules were observed with considerable rigour, both in the learned professions and in those which we now designate as trades. In England they made their way more slowly, and did not receive much countenance from our ancestors, who were always jealous of anything savouring of interference with the freedom of trade. Nevertheless the formation of guilds and companies of tradesmen in England dates probably from the 12th century, and it is almost certain that the institution of apprenticeships cannot be of much later date. In 1388 and 1405 it is noticed in Acts of Parliament. By various subsequent statutes provisions were made for the regulation of the institution, and from them it appears that seven years was its ordinary and normal term in the absence of special arrangement. By the 5th of Eliz. c. 4, this was made the law of the land, and it was enacted that no person should exercise any trade or mystery without having served a seven years' apprenticeship. In no place did the apprentices become so formidable by their numbers and organisation as in London. During the great rebellion they took an active part as a political body, and were conspicuous after the Restoration by being frequently engaged in tumults. It was probably owing to this circumstance, quite as much as to economical considerations of freedom of trade, that the Act of Elizabeth never found much favour with the courts of law. Soon after the great rebellion we find the apprentice laws strongly reprobated by the judges, who endeavoured, on the theory that the Act of Elizabeth could apply to no trades which were not in existence at its date, to limit its operation as far as possible. Such limitation of the Act gave rise to many absurd anomalies and inconsistencies, *e.g.*, that a coachmaker could not make his own wheels, but must buy them of a wheel-wright; while the latter might make both wheels and coaches, because coachmaking was not a trade in England when the Act of Elizabeth was passed. For the like reason all the great manufactures which have arisen in Manchester and Birmingham in modern times were held exempt from the operation of the statute. Concurrently with the dislike to the apprentice laws which such anomalies generated, the doctrines of the celebrated Adam Smith, that all monopolies or restrictions on the freedom of trade were injurious to the public interest, had gradually been making their way, and notwithstanding much opposition, an Act was passed in 1814 (54 Geo. III. c. 96), by which the statute of Elizabeth, in so far as it enacts that no person shall engage in any trade without a seven years' apprenticeship, was wholly repealed. The effect of this Act has been to give every person the fullest right to exercise any occupation or calling of a mechanical or trading kind for which he deems himself qualified. Apprenticeship, therefore, which was formerly a compulsory, has now become a voluntary contract. It is still, however, the usual avenue to such avocations, because experience has shown that it is the only effectual means of acquiring such a knowledge of the mechanical arts as shall enable a man to exercise them with advantage. In the case of the learned professions, the principles and theories which gave birth to corporations with monopolies, and required apprenticeship or its equivalents, have—contrary to what has taken place in trade—been not only maintained but intensified; that is to say, not only have such bodies retained and even extended in some cases their exclusive privileges, but in general no one is allowed to practise in such professions unless his capabilities have been tested and approved by public authority. Thus, no man is allowed to practise law or medicine in any of their branches who has not undergone the appropriate training by attendance at a university or by apprenticeship—sometimes by both combined. Entrance to the church is guarded by similar checks; and even in the case of education great advances have been made to bring the practice of that art under the like restrictions. In such instances the old principle—now abandoned in trade—of granting a monopoly to those possessing a certain standard of qualification is maintained in greater vigour than ever.

As already noticed, Dr Adam Smith and most of his school strongly disapproved of apprenticeship, but only as it would seem when applied to trade and manufactures. They urged that the institution interfered with the property which every man has or ought to have in his own labour, and interfered not only with the liberty of the workman, but with that of such as might choose to employ him, and who were the best judges of his qualification. They further argued, that such laws tended to restrain competition to a much smaller number than would otherwise enter a trade; that a long apprenticeship, or indeed any at all, was unnecessary even for the nicest mechanical arts; that a few weeks or even days were sufficient to enable a man to set to work in such trades as clock and watch making; and that if the workman was from the outset paid the full price of his work, under deduction of such materials as he might spoil from carelessness or inexperience, he would learn his art more effectually, and be more apt to acquire habits of attention and industry, than by working under a master who had a right to share in the produce of his labour. It was further contended that the whole system of apprenticeship, like that of the corporations of which it formed an integral part, was a mere device by which masters sought to limit the number of entrants into their respective trades, and so enhance their monopolies at the expense of the general public. That there is considerable truth in much of this reasoning is undeniable. At the time when Dr Smith began to attack the trade corporations, the narrow and vexatious rules of apprenticeship by which they sought to guard their exclusive privileges were, like their privileges, grievous restraints on the freedom of trade. But taking all this in its worst view will hardly justify the sweeping charges brought against the institution of apprenticeship. It is not conceivable that an institution, which for centuries found acceptance in every part of Europe, should have no better justification than the greed of master workmen. The abolition of the laws which rendered apprenticeship compulsory has not, as Dr Smith and his followers thought, led to its disuse. On the contrary, it or its equivalents have been voluntarily submitted to by such men as desired to exercise a trade to a profit; for the public were not long in discovering that the regularly trained artisan was the only one whose work could be relied on. It is not very easy to see why those principles of monopoly, based on ascertained proficiency, which are so rigorously enforced in the learned professions, should not at least have some application in the case of skilled artisans. It is also worthy of notice that the rise of trades' unions has been coincident with the fall of the old trade corporations - thus indicating that artisans feel the necessity for some more powerful and orderly protection than the mere operation of the blind principle of supply and demand. For these and similar reasons, it is believed that few practical men will in the present day deny the advantages of apprenticeship. No one would probably advocate the restoration of the old guilds with their exclusive privileges; but many would perhaps incline to advise the institution of some order or degree by which, in certain trades, the workman who has passed through a regular apprenticeship may be distinguished from the man who is not so qualified. (F. W. C.)

APRICOT, the fruit of *Prunus armeniaca* (Linn.) or *Armeniaca vulgaris*, according to others. Under the one name it is a species of the genus to which the plums belong, the other establishes it as a distinct genus of the natural order *Rosaceæ*. The apricot is, like the plum, a stone fruit, cultivated generally throughout temperate regions, and used chiefly in the form of preserves and in tarts. The tree is said to be a native of Armenia (hence the name *Armeniaca*), and it is found commonly in mountainous countries throughout Asia. It flowers very early in the season, and is a hardy tree, but the fruit will scarcely ripen in Britain unless the tree is trained against a wall. A great number of varieties of the apricot, as of most cultivated fruits, are distinguished by cultivators. The kernels of several varieties are edible, and in Egypt those of the Musch-Musch variety form a considerable article of commerce. The French liqueur *Eau de Noyaux* is prepared from bitter apricot kernels.

APRIES (Ἀπρίης), the name by which Herodotus and Diodorus designate Pharaoh-Hophra, the eighth king of the twenty-sixth Egyptian dynasty. See EGYPT.

APRIL was, in the old Roman reckoning, the second month of the year, but is counted in the Julian calendar as the fourth. The derivation of the name is unknown, though as far back as Varro we find the traditional etymology, *omnia aperit*, "it opens everything," which is supported by comparison with the modern Greek use of ἄνοιξις (opening) for spring; while some would make out a connection with *Aphrodite* (Venus), and Grimm suggests the name of a hypothetical god or hero, *Aper* or *Aprus*. Among the Romans this month was sacred to Venus, the *Festum Veneris et Fortunæ Virilis* being held on the first day. On the fourth and the five following days, games (*Ludi Megalenses*) were celebrated in honour of Cybele; on the fifth there was the *Festum Fortunæ Publicæ*; on the tenth (?) games in the circus, and on the nineteenth, equestrian combats, in honour of Ceres; on the twenty-first—which was regarded as the birthday of Rome—the *Vinalia urbana*, when the wine of the previous autumn was first tasted; on the twenty-fifth, the *Robigalia*, for the averting of mildew; and on the twenty-eighth and four following days, the riotous Floralia. In many countries of Europe, as England, France, and Germany, the first of April has for long been appropriated to a facetious custom, for which no very satisfactory origin has been assigned. To send an unsuspecting or ignorant person on some bootless errand is the great endeavour of the day. In Scotland the unfortunate subject of the trick is called a gowk—which has now, though the words were probably at one time different, the meaning both of "fool" and "cuckoo,"—and the mischievous errand-sending is "hunting a gowk." In France the dupe is called *poisson d'Avril*, or April-fish. One remarkable theory traces the custom to Noah, as sending out his dove on such a quest; it is also referred either to the miracle plays representing the sending of our Saviour from Annas to Caiaphas and from Pilate to Herod, or to the change, in France, in 1564, of New Year's day to the first of January, which left the first of April destitute of anything but a burlesque of its former festivities; and more recently an identification has been attempted with the Hindoo festival of Huli, which is celebrated in a similar manner on the 31st of March. No references to all-fools'-day have been found in our earlier literature; and it seems that both England and Germany have derived the fashion from France. St George's day is the twenty-third of the month; and St Mark's Eve, with its superstition about those who were doomed to die, falls on the twenty-fourth. In China the symbolical ploughing of the earth by the emperor and princes of the blood takes place in their third month, which frequently corresponds to our April; and in Japan a pleasant domestic festival, called the Feast of Dolls, is celebrated in the same month. The days of April (*journées d'Avril*) is a name appropriated in French history to a series of insurrections at Lyons, Paris, and elsewhere, against the government of Louis Philippe in 1834, which led to violent repressive measures, and to a famous trial known as the *Procès d'Avril*. (See Chambers's *Book of Days*; Grimm's *Geschichte der Deutschen Sprache*, cap. "Monate.")

A PRIORI and A POSTERIORI. The philosophical distinction expressed by these terms is to be explained by referring to the phraseology of Aristotle. According to him there may be a double starting-point in knowledge. When our individual progress in learning is chiefly considered, the things with which we are first and best acquainted may be termed earlier and *prior*; whereas the truths of a more general, primary, and fundamental character, to which we are subsequently led, have a later and *posterior* position. But if we lose sight of our personal interest in knowledge, then the priority may be more justly claimed by whatever is the cause or principle from which something else springs. In this sense the causal, original, and primary in the objective world is by nature prior (πρότερον φύσει); whilst the secondary and derivative existence is posterior. Priority in the first acceptation is only relative to us, and for general purposes may be called accidental; in the second acceptation, the priority is absolute, and without qualification. It is the second acceptation which Aristotle laid down as the properly philosophical one, and which regulates the usage of the phrases *a priori* and *a posteriori* by the schoolmen. In that sense of the term there can evidently be no *a priori* demonstration of first and fundamental principles. According to Aquinas, for example, there can be no *a priori* knowledge of God; because He, as uncaused and uncreated, cannot be deduced from anything prior in causation to Himself, and can only be apprehended rationally by means of that which is consequent upon His action, viz., the creatures of the natural world. In other words, our knowledge of Him must be *a posteriori*. It is obvious that science in the highest sense must be *a priori*, if *vere scire est per causas scire*; *i.e.*, the knowledge must spring from an insight into causes, which are the true primaries. By an extension of this usage an argument is said to follow an *a priori* path, when from the basis of some conception it proceeds to evolve by analysis all or some of the logical consequences; whereas, the mode of reasoning, which endeavours to gather into a single formula the various facts of observation, is described as *a posteriori*. The argument of Anselm, which, from the mere conception of God, proposes to deduce his existence, is an example of *a priori* reasoning. An *a priori* reasoner has to predict what is or will be, by considering what ought to be in accordance with certain presuppositions. He tries by argument to assign beforehand the place of a fact which may not yet have been discovered by observation. From the analysis of certain given conditions, or by constructing the total product from some given elements, he seeks to anticipate experience. Of course, if the original conception be bad or defective, the conclusions will be false or inadequate. Often too, what claims to be the mere deduction from a conception, is secretly and perhaps unconsciously supplemented by more efficient elements of proof. It is this circumstance, that imperfect knowledge is taken as the ground for further conclusions, which has brought *a priori* reasoning into discredit. Apart from these defects, however, this style of argumentation merely expresses the natural and blameless tendency of the mind to make every acquired truth a sort of lever and fulcrum from which to move the yet undiscovered and untried; and error is introduced only where there is a failure to correct this tendency by constant recurrence to the processes of verification. The *a priori* argument is based upon what was originally given through experience; but before this experiential truth becomes *a priori*, it must lose its first and empirical character, and be invested with the attributes of universality and necessity. In this sense, which since the time of Kant has been commonly given to the word, the *a priori* is the opposite of the empirical and contingent. Any truth which is relatively universal and necessary may in its own sphere form the basis of an *a priori* argument; and if there be anything which is absolutely universal and necessary throughout the whole range of knowledge, it will be in a supreme sense *a priori*. Such, according to Kant, is the self-contained and original faculty of mind, the forms and powers of the intellect and senses, as contradistinguished from the materials presented by the senses and elaborated by the understanding. To ascertain the special constitution of this *a priori* region, thus marked out by the criteria of universality and necessity, to determine the features of thought when it is independent of and prior to all experience, was the theme of the *Critique of the Pure Reason*. The general or universal form and faculty of knowledge, thought in its native purity, constitutes the *a priori* element: whilst the particularising data of experience, drifting in from the unknowable thing-in-itself, make up the region of the *a posteriori*. An example of an *a priori* science, according to Kant, in this sense of the term, as not dependent upon experience, is seen in pure mathematics; and there may also, according to him, be a pure or *a priori* philosophy of nature; but there can be no pure or *a priori* doctrine of the ultimate ideas which regulate experience,—that is, metaphysics in the older sense is impossible. (W. W.)

APSE (Gr. ἀψίς; Lat. *absis, tribuna, concha*; Fr. *abside, chevet, rond-point;* Ital. *apside, tribuna*; Ger. *Ablauf*), the semicircular or polygonal termination to a church. These forms were no doubt derived from the *concha* or *bema*, in the classic and early Christian basilica. In both cases it was the place appropriated to those who administered justice, the prætor's chair in the one being represented by the bishop's throne in the other. The altar stood not within the apse, but on the chord of its arc. Sometimes the apse is a simple semicircle; sometimes in large churches out of this a smaller semicircle springs, as Becket's Crown at Canterbury, and at Sens, Langres, and in many other churches abroad. Sometimes the choir finishes with three apses—one to the central aisle, and one to each side aisle, as at Autun. Sometimes the plan is a semicircle, each bay of which has a projecting semicircular apse, forming a sort of cluster of apses, as at Beauvais, Troyes, Tours, &c. The later choir at Mans is encircled by no less than thirteen apses, the centre one being twice the depth of the others, and forming the Lady-chapel. In some small churches of the Norman period, there is a sort of *double chancel*, one square, and the other an apse projecting eastward, each of which has its own arch, as at Sutton, East Ham, Darent, &c. Large circular and polygonal apses generally have radiating chapels within, as at Westminster Abbey. The earliest cathedral at Canterbury had an apse at each end, if we may trust the old plan; and there are several instances of the same kind in France and Germany. Apses project from the north and south ends of the transepts, and from their east sides in a few cases abroad, the only example of this in England being at Norwich.

APSHERON, a peninsula of Asia, in Georgia, extending from the eastern extremity of the Caucasus range for about 40 miles into the Caspian Sea, and terminating in Cape Apsheron. It produces naphtha, salt, and saffron in great abundance; and has long been celebrated among the fire-worshippers of Asia for the sacred fires that issue from its soil. On its southern coast is the port of Baku.

APT, the Roman *Apta Julia*, a town of France, in the department of Vaucluse, situated on the left bank of the Calavon, a tributary of the Durance, 30 miles east of Avignon. It is surrounded by ancient and massive walls, and is well built, although several of its streets are narrow and irregular. The chief object of interest is the cathedral, a building combining different styles of architecture, founded about the year 1050 on the site of a much older edifice, but not completed until the latter half of the 17th century. There are many Roman remains in and near the town, including a fine bridge, which is said to have been constructed by Julius Cæsar. The chief manufactures of Apt are those of woollen and cotton goods, silk, confectionery, earthenware, candles, leather, and brandy, and there is besides a considerable trade in fruit, grain, and cattle. Apt was at one time the chief town of the Vulgientes, a Gallic tribe; it was destroyed by Julius Cæsar, who subsequently restored it, conferring upon it the title Julia; it was much injured by the Lombards and the Saracens, but its fortifications were rebuilt by the counts of Provence. Population (1872), 5892.

APULEIUS, LUCIUS, celebrated as a philosopher and a writer of romance, was born at Madaura in Numidia, about 125 A.D. As the son of one of the principal inhabitants, he received an excellent education, first at Carthage and subsequently at Athens. After leaving Athens he undertook a long course of travel, principally with the view of obtaining initiation into religious mysteries. On a journey to Alexandria he fell sick at Œa (Tripoli), and was received into the house of Sicinius Pontianus, a former fellow-student. The widowed mother of Pontianus, Pudentilla, became enamoured of the handsome young philosopher, who, at her son's request, as he affirms, consented to marry her. The lady's wealth rendered this step distasteful to the other members of her family, by whom, after the premature death of Pontianus, Apuleius was indicted on a charge of having gained her affections by magical arts. He easily established his innocence, and his spirited, highly entertaining, but inordinately long defence (*Apologia, sive de Magia*), is our principal authority for his biography. From allusions in his subsequent writings, and the mention of him by St Augustine, we gather that the remainder of his prosperous life was devoted to literature and philosophy, that he exercised the priestly office, and frequently declaimed in public; and that statues were erected in his honour by Carthage and other cities. Many errors have found their way into his biography, from the supposition of his identity to a certain extent with Lucius, the hero of his romance. The contrary appears from the introduction of Lucius as a Greek, who professes to have only with great difficulty acquired Latin, Apuleius's own mother tongue. Lucius also takes a vow of poverty and chastity, which must have been but ill observed by the spouse of the opulent and amorous Pudentilla.

There is little of Apuleius's own invention in the work on which his fame principally rests. The *Metamorphoses* or *Golden Ass* (which latter title seems not to be the author's own, but to have been bestowed in compliment), was founded on a narrative in the *Metamorphoses* of

Lucius of Patræ, a work extant in the time of Photius. From Photius's account (impugned however by Wieland and P. L. Courier), this book would seem to have consisted of a collection of marvellous stories, related in an inartistic fashion, and in perfect good faith. The literary capabilities of this particular narrative attracted the attention of Apuleius's contemporary, Lucian, who proceeded to work it up in his own manner, adhering, as Photius seems to indicate, very closely to the original, but giving it a comic and satiric turn. Apuleius followed this rifacimento, making it, however, the groundwork of an elaborate romance, interspersed with numerous episodes, of which the beautiful story of Cupid and Psyche is the most celebrated, and altering the denouement to suit the religious revival of which he was an apostle. There is no reason to conclude with Warburton, that he wrote in direct antagonism to Christianity; or with Thomas Taylor, that "his intention was to show that the man who gives himself to a voluptuous life becomes a beast." The book is, nevertheless, a remarkable illustration of the contemporary reaction against a period of scepticism, of the general appetite for miracle and magic, and of the influx of Oriental and Egyptian ideas into the old theology. It is also composed with a well-marked literary aim, defined by Kretzschmann as the emulation of the Greek sophists, and the transplantation of their *tours de force* into the Latin language. Nothing, indeed, is more characteristic of Apuleius than his versatility, unless that it be his ostentation and self-confidence in the display of it. The dignified, the ludicrous, the voluptuous, the horrible, succeed each other with bewildering rapidity; fancy and feeling are everywhere apparent, but not less so affectation, meretricious ornament, and that effort to say everything finely which prevents anything being said well. The Latinity has a strong African colouring, and is crammed with obsolete words, agreeably to the taste of the time. Few books accordingly suffer less by translation. When these defects are mitigated or overlooked, the *Golden Ass* will be pronounced a most successful work, original in treatment though not in invention, invaluable as an illustration of ancient manners, and full of entertainment from beginning to end. The most famous and poetically beautiful portion is the episode of Cupid and Psyche, adapted from a popular legend of which traces are found in most fairy mythologies, which explains the seeming incongruity of its being placed in the mouth of an old hag. As observed by Friedländer, this discriminating recognition of the beauty of a wild flower of folk lore is as much to the credit of Apuleius's taste and feeling as the invention of it could have been to his imagination. The allegorical purport he has infused into it is his own, and entirely in the spirit of the Platonic philosophy. Don Quixote's adventure with the wineskins, and Gil Blas's captivity among the robbers, are palpably borrowed from Apuleius; and several of his humorous episodes, probably current as popular stories long before his time, reappear in Boccaccio.

Of Apuleius's other writings, the *Apology* has been already mentioned. The *Florida* are a collection of excerpts from his declamations, ingenious but highly affected, and in general perfect examples of the sophistical art of saying nothing with emphasis. The pleasing little tract *On the God of Socrates* expounds the Platonic doctrine of beneficent dæmons. Two books on Plato treat of his life, and his physical and ethical philosophy; a third, treating of logic, is generally considered spurious. Apuleius informs us that he had also composed numerous poems in almost all possible styles, and several works on natural history, some in Greek. In the preparation of these he seems to have attended more closely to actual anatomical research than was customary with ancient naturalists.

The character of Apuleius, as delineated by himself, is attractive; he appears vehement and passionate, but devoid of rancour; enterprising, munificent, genial, and an enthusiast for the beautiful and good. His vanity and love of display are conspicuous, but are extenuated by a genuine thirst for knowledge, and a surprising versatility of attainments. His place in letters is accidentally more important than his genius strictly entitles him to hold. He is the only extant example in Latin literature of an accomplished sophist in the good sense of the term. The loss of other ancient romances has secured him a peculiar influence on modern fiction; while his chronological position in a transitional period renders him at once the evening star of the Platonic, and the morning star of the Neoplatonic philosophy.

The most complete edition of Apuleius is Oudendorp's (Lugd. Bat. 1786–1823); the best modern edition is Hildebrand's (Leipsic, 1842). The translations and imitations of the *Golden Ass* in modern languages are innumerable. The episode of Psyche has afforded the subject of a drama to Thomas Heywood, and of narrative poems to Shakerley Marmion, and Mrs Tighe. There are good English versions by Sir G. Head, and in Bohn's Classical Library. The style of Apuleius has been thoroughly investigated by L. Kretzschmann, *De Latinitate L. Apulei Madaurensis* (Regimonti, 1865). (R. G.)

APULIA, the name applied to a district of southern Italy, the limits of which were not very definitely or permanently marked. It is usually regarded as having been bounded by the country of the Frentani on the N., Samnium on the W., Calabria and Lucania on the S., and the Adriatic on the E. The northern portion comprised the district sloping eastward from the Apennines, but did not take in any part of the mountains themselves; while the southern portion was occupied by a rocky off-shoot of the main chain, which left only a narrow but fertile strip of land along the sea. On the northern part of the coast was the remarkable mountain-mass of Garganus, forming an enormous promontory. Apulia was watered by the Tifernus (*Biferno*), the Frento (*Fortore*), the Cerbalus (*Cervaro*), the Aufidus (*Ofanto*), and a number of intermittent mountain streams. The soil for the most part was calcareous and arid, but in winter afforded abundant pasturage for the sheep, that in ancient times as now were driven during the summer to the neighbouring highlands of Samnium. Of the mingled population of Apulia, the Apulians proper (of Oscan race, it is supposed), the Daunians (perhaps of Pelasgian origin), and the Peucetians or Pœdiculi (likewise Pelasgian), seem to have been the principal elements. The prevalent language, according to Mommsen's investigations, was distinct from the Oscan and related to the Greek. Direct Greek influence—probably emanating from Tarentum—is evident in the workmanship and inscriptions of the coins and vases and other remains which have been discovered throughout the region. The more important towns were Larinum (?), Teanum, Luceria, Arpi, Salapia, Sipontum, Canusium, Barium, Egnatia, and Venusia. Reduced under Roman dominion in the 4th century B.C., Apulia for the most part continued true to the Roman cause till the time of the second Punic war, when it was greatly distracted and suffered grievously from the hostile operations of both the belligerents. It belonged to the second region of Augustus, and from the reign of Constantine was governed along with Calabria by a "*Corrector.*" For several centuries after 476 it was alternately under the power of the Lombards, the Goths, the Saracens, and the emperors of the East; and about the 10th century was regularly governed by the last by means of a "catapan" or deputy, who has left the designation of his office, *Catapanata*, in the modern corruption *Capitanata*, applied to the northern portion of the present Apulia. It was conquered by the Normans under William Bras-de-Fer, who took the title of *Comes Apuliæ* in 1042, was raised along with Calabria to a dukedom by Robert Guiscard in 1057, and in 1127 was united to the Sicilian monarchy. The name

Apulia is still employed as a geographical, but no longer as an ethnological or political designation.

APURE, a river of Venezuela, formed by the confluence of the Orivante and the Sarare in 7° N. lat., and 71° W. long., and joining the Orinoco, after a course of about 500 miles. Its chief tributaries are the Caparo and the Portuguesa.

APURIMAC, or TAMBO, a Peruvian river which rises in the lagoon of Villafro, near Caylloma, flows in a generally northward direction, and, receiving the waters of the Velille, the San Tomas, the Mamara, the Pachachaca, the Pampas, the Mantaro, and the Perene, falls into the Ucayali, an affluent of the Amazon. The river formed by the Tambo—or Catongo, as it is called in this part of its course—and the Mantaro receives the name of Ene, and is joined by the Perene, a river large enough for the passage of steamers. About 30 miles further down it forms a great cataract, which breaks the navigation. After receiving the Muyupu and the Vilcamayu or Urubamba, the stream, under the name of Ucayali, flows north to join the other head-streams of the Amazon near Nauta. The navigation of the Apurimac below the falls is greatly hindered by its strong and rapid current. The whole length of its course is about 600 miles.

AQUAMBO or AKUAMU, a country in the interior of the Gold Coast of Africa, extending along both banks of the Rio Volta or Aswada. The portion to the west of the river is under British protection; and that on the east, with the exception of a narrow strip along the bank, is subject to the king of Dahomey.

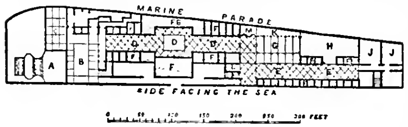
AQUAPIM, a country of considerable extent in the interior of the Gold Coast of Africa, immediately behind Accra. It is watered by the Densu, Dinskoi, or Seccoom, and is finely diversified with cultivated valleys and wooded hills of considerable elevation. The most important place is Akropong.

AQUARIANS, a name given to various sects of Christians in the primitive church who substituted water for wine in the communion service. This they did on principles of abstinence and temperance, or because they thought it unlawful under any circumstances to eat flesh or drink wine. Epiphanius calls them *Encratites*, from their abstinence; Augustine, *Aquarians*, from their use of water; and Theodoret, *Hydroparastatæ*, because they offered water instead of wine. Entirely distinct from those Aquarians upon principle, were others who used water at morning communion in order that they might not be discovered by the smell of wine.

AQUARIUM. This word is used to denote a vessel, or collection of vessels, in which marine or fresh water animals may be kept, and in which marine or sweet water plants may be grown. The invention or rather growth of the modern aquarium cannot, in the absence of precise data, be accurately traced. The aquarium, as we find it at Hamburg or Brighton, has, like many other things now in daily use, been elaborated from small beginnings. It is known that more than two centuries ago marine animals were, for the purposes of study and observation, removed from the sea and kept in confinement; and there is extant a drawing, of the date of 1742, which represents the form of an aquarium containing zoophytes. Esper, a distinguished entomologist, a century ago kept aquatic insects in water for observation. Sir John Graham Dalyell, the author of *Rare and Remarkable Animals of Scotland*, 2 vols. 4to, 1847–48, *The Power of the Creator displayed in the Creation*, 3 vols. 4to, 1851–58, and numerous other works, was during his lifetime a keen student of marine animals; and, at his house in Edinburgh, he had constructed for the purposes of observation an aquarium of a very humble kind indeed, but quite sufficient for his purpose. It is well known that some of the animals which he kept for the purposes of study lived for a very long period in confinement: one sea anemone is mentioned on good authority as having been taken from the sea in the year 1828, and being alive and well in 1873 (W. A. Lloyd). Sir John's tanks, as has been stated, were of the humblest description, and never contained any of that vegetation which forms so beautiful and interesting a feature of the modern aquarium, and which, as Priestley had discovered long before, purifies the water in which it is kept growing. About the year 1839 a movement was made towards the construction of aquariums of a more elaborate description, which lasted for more than twenty years during which time a large number were made, and many descriptive works published on the subject. Agencies were during that period established in London and elsewhere for the supply of animals, and some at the same time made it a business to purvey sea water—the obtaining of this, and keeping it fresh, being with many persons who lived far from the sea a great difficulty. Indeed the difficulty was so great that an artificial compound was in numerous instances resorted to for lack of genuine sea-water. A solution of this difficulty came tardily, in 1841. Mr Ward at that time constructed in London a fresh-water aquarium, in which aquatic plants were very successfully grown for the purpose of keeping the water pure and the animals healthy, and a year later, Dr George Johnston of Berwick-on-Tweed, accidentally discovered, in the course of making an experiment for another purpose, that the animal and plant life of the sea could also be made to support each other. For a period of sixty days he kept some animals in a jar without once changing the water, and thus solved the problem. Early in 1847 Mrs Thynne of London successfully investigated the problem, whether it was possible to keep the animals in good condition of health without changing the water. In 1849 Mr R. Warington, also of London, and afterwards Mr P. H. Gosse, conducted successful experiments having for their object the balancing of vegetable and animal life, which afterwards came to be thoroughly recognised. Sea-weeds, however, do not bear transplanting, but sea-water is so impregnated with the seeds or germs of vegetable life, that when a few stones or fragments of rock are taken from the ocean, marine vegetation speedily commences and proceeds. Mr Price, Mr Lankester, Mr Bowerbank, and others, also made experiments in the same direction, and in 1853 a fish-house or aquarium of considerable size was constructed by the Zoological Society of London in their garden in the Regent's Park. This erection gave such an impetus to the popular aquarium movement as rendered it almost a mania, and for a year or two these scientific toys, some of them of large size, became much appreciated household ornaments. The movement was further accelerated by Mr Gosse and Mr Warington, who published formulæ for the manufacture of artificial salt water, in which sea animals would thrive as well as in their native element. Many large public aquariums have been erected since the example was set by the Zoological Society of London. A great aquarium has been usually a popular feature of the numerous Continental fishery-exhibitions held since 1860, particularly at those of Amsterdam, Boulogne, Havre, Arcachon, and the Hague. These, of course, were temporary aquariums, ending when the exhibition of which they formed a part came to a close; but permanent aquariums are now a feature of several large towns and cities. In England there is a very large aquarium at Brighton; while at the Crystal Palace there is one on a smaller scale, as also at Manchester and Southport, and preparations are being made [1874] for the erection of similar edifices in other towns and cities of Great Britain. The aquarium at Hamburg has already been mentioned; there are others at Berlin and Vienna; and the aquarium at Naples affords special accommodation and opportunity for skilled naturalists pursuing delicate scientific investigations.

The modern aquarium is essentially different from the vivaria or fish-stews of ancient times. These were constructed for every day kitchen use, for the purpose of supplying the tables of their wealthy possessors with various kinds of fish; some of those kept being of great value. Wonderful stories are told by ancient authors of the pains taken to procure fine breeds of fish, and the care with which they were fed and fattened for use. Fish were borrowed and returned; the keeping of them became a fashion, and extravagant sums of money were expended on the purchase of rare kinds. The remains of vivaria and fish-stews are still to be found in the neighbourhood of Naples, and at other places in Italy.

The dimensions of the great aquarium at Brighton are as follows:—Its area is 715 feet in length by 100 feet in breadth. It contains many tanks, some of them being of



Ground Plan of Brighton Aquarium.

A, entrance court; B, entrance-hall and reading-room; C, restaurant; D, D, western corridor; E, E, eastern corridor; F, F, tanks (all shaded in plan); F 6, the large tank, No. 6; G, conservatory; H, rockwork, fernery, and cascade; I, I, space with tanks on table; J, J, engine, stores, &c.; K, rockwork with ponds for seal, &c.; L, grotto; M, heating apparatus.

vast capacity; there is one in particular (No. 6) which contains 110,000 gallons of water, and has a plate-glass front 130 feet long, through which the habits of very large fish may be studied. The rock-work of the tanks is entirely artificial, and admirably adapted to afford shelter to the fish and crustaceans which disport in them. The management of a large aquarium, such as that at the Crystal Palace or at Brighton, involves constant anxiety and daily trouble: the fish must of course be fed so that they may enjoy good health, and to ensure this they must live under conditions as nearly as possible the same as they have been accustomed to in the waters from which they have been taken. At one time much difficulty was experienced in keeping the inhabitants of sweet-water tanks in good health; in numerous instances the fish died in a day or two after their places of residence had been changed; and it wss not till after many different plans had been tried, that safe modes of keeping them in a healthy state were found out. Thousands of fish died in ornamental fresh-water tanks from over-attention, from a too frequent changing of the water, and from lack of a supply of those elements of growth which are essential to all animated nature.

The aquariums at Brighton and the Crystal Palace exemplify two distinct systems of construction and management. At the former there is no actual circulation of water from one tank to another—but it can, if necessary, be renewed from the sea; the mass of the water in the reserve cisterns is small as compared with that in the show tanks, and aeration is effected by pumping air into the tanks through tubes of large diameter. Purification of the water is also assisted by the presence of large bivalve molluscs in the tanks. At the Crystal Palace aquarium, a constant circulation is maintained from one tank to another; the bulk of water in the reservoir is five times as much as that in the show tanks, while aeration is accomplished by carrying a main over their entire length, from which, under pressure, a small stream of water pours from a tap into each, breaking the surface of the water, and carrying down to the bottom of the tanks, and distributing over the body of their contents, myriads of minute bubbles of air, which present an enormous oxidising surface to the water, rendering it bright and sparkling.

It does not answer very well, even when an aquarium is at the sea-side, to be constantly changing the water, as the new supply is so disturbed and impregnated with impurities as to be fatal to delicate animals, besides not being in a proper state for exhibition. Some of the inhabitants of an aquarium foul the water very much more than others, notably the flat fish family, and provision has to be made for this by putting such other animals in the same tank as will aid in purifying the water. Various small animals have of course to be provided as food for the larger marine specimens, others of them act as scavengers, helping to keep the water constantly sweet and clean. The light admitted to the fish in the tanks is also a matter of careful adjustment. As the animal life and vegetable life mutually support each other, the kind of material necessary for maintaining the "compensating system" must be watchfully supplied. Mr W. R. Hughes of Birmingham recommends the growth of sea-lettuce (*Ulva latissima*) in tanks, as suitable both for oxygenating the water and for food for the fishes; the stock plants being introduced in the autumn months, when they are loaded with spores. Now that such excellent aquariums as those at Brighton, Manchester, Southport, and Sydenham are in full working order, the construction of others will not be difficult, even when projected on a larger scale. Distance from the sea is of no consequence, as sea-water may be obtained by railway, and can be kept stored as already suggested.

Scientific discovery, or the promotion of experiments in natural history, is usually no direct part of the plan of modern aquariums, except in so far as this may be incidental to the daily conduct of the collection. Nevertheless, it is not too much to expect that the aquariums already in existence, and those which are projected, may be made useful in determining many questions connected with the life and growth of our food fishes, in regard to which naturalists and economists are alike ignorant. The fish of which we know most is the salmon, and our knowledge of that "monarch of the brook" arises from the fact of its being accessible to constant observation. It would tend to the better regulation of our fisheries, and to the augmentation of our food supplies, if we knew as much about the herring or the haddock as we know about the salmon. Were a large marine observatory erected by the State, say at Brighton, or were the present aquarium there considerably extended, the best results might follow. Precise information might be obtained as to the period of spawning of the common herring, the length of time which the ova require to come to life, and the age at which the fish becomes reproductive. The conditions under which fish grow and remain in good health, the best kinds of food on which to feed them, the best methods of protecting them from their numerous enemies, are all questions which a properly conducted aquarium would aid our naturalists to study. It is well known that very uneconomical modes of fishing are at present resorted to, and that the largest portion of our fish is captured at a time when fish ought not to be captured—at a time, indeed, when they are most unfit for use. It is only by studying the habits of these denizens of the ocean, in some place where they can be constantly under observation,—such as a great aquarium, where the conditions of their captivity should resemble as much as possible their native *habitat*,—that we can ever hope to fathom the mysteries of the great deep, and ultimately have at our command the treasures of the sea. (See Gosse, *The Aquarium*, 1856; the Guide-Books of the Crystal Palace and Brighton Aquariums; Hughes, *On the Principles and Management of the Marine Aquarium*, 1874.) (J. G. B.)

AQUEDUCT

AQUEDUCT, a conduit or channel for the conveyance of water (Lat. *aquæductus*), but commonly a structure of masonry erected to conduct water across a valley at a high level, though structures of this kind would be more properly termed aqueduct bridges. This distinction it is necessary to bear in mind, more particularly when dealing with the undertakings of this class carried out by the Greeks and Romans respectively, because, from the fact of the former having apparently seldom if ever constructed aqueduct bridges, it has been usual to institute a very unfavourable comparison between them and the Romans, who, with imperial disdain of obstacles, furnished the cities of their immense empire with a series of constructions of this kind for the supply of water, which still in their ruins excite our astonishment. True to the difference in national genius the Greeks, following the analogy of nature, in which in their own country they saw the water collected in the hills passing for miles along subterranean courses, and issuing in cool fountains at the coast, adapted their system of conduits to the physical formation of a district, cutting tunnels and canals, rather than bridging over valleys, and as a consequence no conspicuous monument of their system now remains. But even if what they did was so little as to justify Strabo (v. p. 235) in charging them with neglect in this matter as compared with the carefulness of the Romans, it is still clear from the records that they accomplished much, and that in this, as in other respects, they were the instructors of the Romans. It is here to be premised that the term aqueduct applies only to the conveyance of such water as was used for drinking or other useful purposes, and not to the draining of marshes, though in both cases the works may often have been of the same kind. The insufficiency of water, supplied by natural springs and cisterns hewn in the rock, which in an early age had satisfied the small communities of Greece, had become a pressing public question by the time of the Tyrants, of whom Polycrates of Samus and Pisistratus of Athens distinguished their rule by extensive works to meet the exigencies of their states. For this purpose the former obtained the services of Eupalinus, an engineer celebrated for the skill with which he had carried out the works for the water supply of Megara, under the direction of the Tyrant Theagenes (*circa* 625 B.C.) At Samus the difficulty lay in a hill which rose between the town and the water source. Through this hill Eupalinus cut a tunnel 8 feet broad, 8 feet high, and 4200 feet long, building within the tunnel a channel 3 feet broad and 11 ells deep. The water, flowing by an accurately reckoned declivity, and all along open to the fresh air, was received at the lower end by a conduit of masonry, and so led into the town, where it supplied fountains, pipes, baths, cloacæ, &c., and ultimately passed into the harbour. In Athens, under the rule of Pisistratus (B.C. 560), a similarly extensive, if less difficult, series of works was completed to bring water from the hills Hymettus, Pentelicus, and Parnes. From Hymettus were two conduits passing under the bed of the Ilissus, and most part of the course cut in the rock. Pentelicus, richer in water, supplied another conduit, which can still be traced from the modern village of Chalandri by the air shafts built several feet above the ground, and at a distance apart of 40–50 metres; the diameter of these shafts is 4–5 feet, and the number of them still preserved is about sixty. Tributary channels conveyed into the main stream the waters of the district through which it passed. Outside Athens, those two conduits met in a large reservoir, from which the water was distributed by a ramification of underground channels throughout the city. These latter channels vary in form, being partly round, partly square, and generally walled with stone; the chief one, that under the bazaar, is sufficiently high and broad to allow two men to pass in it. Sometimes pipes of baked clay were laid within them. The conduit from Mount Parnes appears to have been reconstructed in later times. Some of these aqueducts continue to supply Athens to this day, and are described as marvels of enterprise and skill (E. Curtius, *über die Wasserbauten der Hellenen*, in the *Archäol. Zeit.* 1847, p. 19). In Sicily, the works by which Empedocles, it is said, brought the water into the town of Selinus, are no longer visible; but it is probable that, like those of Syracuse, they consisted chiefly of tunnels and pipes laid under ground. The system of conduits in Syracuse which Thucydides says (vi. 100) the Athenians partly destroyed on the Sicilian expedition, still supplies the town with an abundance of drinkable water; and at one point, where the tunnel passes under the sea to the island of Ortygia, presents what has long been regarded as a remarkable achievement for early times. An example of what appears to have been the earliest form of aqueduct in Greece has been discovered in the island of Cos (Ross, *Inselreise*, iii. p. 131), beside the fountain Burinna on Mount Oromedon. It consists of a bell-shaped chamber, built underground in the hill side, to receive the water of the spring and keep it cool; a shaft rising from the top of the chamber supplied fresh air. From this reservoir the water was led by a subterranean channel, 35 metres long and 2 metres high.

Of the constructions for the conveyance of water in Italy in early times, there is an example at Tusculum, consisting of an oblong basin, divided into several chambers, which received the water of a spring, and then distributed it by pipes (*tubi, fistulæ*) or canals. The basin is built of blocks of stone, which, along the sides, overlap each other, till they meet and form a roof—a principle of building which was afterwards supplanted by vaulting, and which occurs also in the earliest Greek masonry. The pipes were either of lead or baked clay. When the course lay in soil, gullies were cut and conduits of masonry built within them. When rocky ground intervened, tunnels were pierced, and in both cases shafts (*spiramen, lumen*) were made at intervals of about 240 feet, to admit light and fresh air. The inside of the walls of these channels received a coating impervious to water, composed of chalk and crushed fragments of tile. Where the course was interrupted by an inequality in the ground, a vertical pipe (*venter*) was placed reaching to the surface or above it. The water rushing up this pipe was freshened by contact with the air, and again fell back to the new course which it had to take. Works of this kind, undertaken for the public convenience, were paid for out of the public purse, a tax being levied for the use of the water.

If, to obtain a proper incline, the water-course had to be carried above ground, the simple plan was to support it on a stone wall, and in this case the conduit itself was also built of blocks of stone, coated with a stucco impervious to water. But since a solid wall across a valley would have cut off the usual traffic, it was found necessary to break up the wall, by means of arches, into a series of pillars, and with this commenced the system of aqueduct bridges, which have proved to be the most striking monuments of the Roman empire. As perhaps the best known instance of this double purpose, of an archway under which traffic might pass, and over which water might be conveyed, there is the Porta Maggiore at Rome (Plate III.) The waters conveyed over it in two separate channels, are the AQUA CLAUDIA and the ANIO NOVUS, and from the three inscriptions above the arches it appears (1.)—that the Emperor Claudius had constructed the so-called Aqua Claudia Aqueduct from the springs Cæruleus and Curtius, 45 miles from Rome; (2.) that the same emperor had constructed the so-called Anio Novus Aqueduct from the 62d milestone from Rome; (3.) that the Emperors Vespasian and Titus had restored these splendid undertakings of Claudius. Both aqueducts had been begun by Caligula, 38 A.D., and were completed ten years after by Claudius. The two springs from which the Aqua Claudia took its rise were in the Sabine hills near the 35th milestone, on the Via Sublacensis. It was augmented by part of the Aqua Martia, famous for the goodness of its water, and, owing to bends in the course, reached the length of 45 miles, as stated in the inscription, 35 miles of it being under and 10 above ground. The Anio Novus, so called to distinguish it from an older aqueduct, the Anio Vetus, took its rise in the river Anio at the 62d milestone, on the road just named, the water being first collected in a large basin, where it was allowed to purify itself. At the 32d milestone it was augmented by the clearer water of the spring, *rivus Herculaneus*. The entire length of 62 miles was partly above and partly below ground. About 6 miles from Rome it approached the Aqua Claudia, and from that point the two waters travelled together to the city in two distinct channels, one above the other, and supported by a chain of arches, which at one place reached the height of 109 feet. But in height these arches must yield to those of the aqueduct at Nismes, the ancient Nemausus, erected in the time of Augustus, which rose to 180 feet. The Pont du Gard, as the aqueduct at Nismes is now called, consists, as will be seen from Plate IV., of three rows of arches striding across the valley of the river Gardon. In the lowermost row are six arches, of which one has a span of 75 feet, the others each 60 feet. In the second row are twelve arches, each with a span of 75 feet. In the third row are thirty-six smaller arches, immediately above which was the water-course. As a bridge, the Pont du Gard has no rival for lightness and boldness of design among the existing remains of works of this class carried out in Roman times..

Besides the two principal aqueducts at Rome already described, there remain to be noticed twelve more which assisted in the supply of water for the city. These are (1.) AQUA APPIA, which took its rise at the foot of the Alban mountains on the Præneste road, between the 7th and 8th milestones, and measured from its source to the Porta Trigemina 11,180 paces, of which 11,130 were below ground. It appears to have been the first important enterprise of the kind at Rome, and was the work of the old Censor Appius Claudius, from whom it derived its name. The date of its construction was the year of Rome 442, according to Frontinus, an overseer of aqueducts (*curator aquarum*) under the empire, whose work *De Aquæduct. urb. Romæ* we still possess. (2.) ANIO VETUS, constructed forty years after the last-mentioned aqueduct, by the Censor Manlius Curius Dentatus, with the help of L. Papirius Censor, who finished it. From its source near Tivoli, on the left side of the Anio, it flowed 43,000 paces, of which 42,779 were below ground, and 221 above. At the distance of 2 miles from Rome (Frontinus, i. 21) it parted into two courses, one of which led to the *horti asiniani*, and was thence distributed; while the other (*rectus ductus*) led by the temple of Spes to the Esquiline gate, the site of which was near the modern Villa Negroni, where, in 1861, was found a subterranean conduit and an inscribed stone, which left no doubt as to its having been one of the stones set up to mark the distances of the Anio Vetus. (3.) AQUA MARTIA, rising on the left side of the Via Valeria, traversed 61,710 paces, of which 54,247 were underground, and the remaining distance carried partly on solid wall and partly on arches. It was the work of Quintus Martius Rex, not of Ancus Martius the fourth king of Rome, as Pliny (*N.H.*, xxxi. 3) fancied, and took its name from its constructor. Its waters were celebrated for their coolness and excellent quality. (4.) AQUA TEPULA, from its source in the district of Tusculum, flowed 10,000 paces, mostly above ground, and on the same series of arches as carried the Aqua Martia, but at a higher level. It was the work of the Censors Cn. Servilius Cæpio and L. Crassus Longinus, and was completed in the year 126 B.C. Again, partly on the same structure of arches, and with a still higher channel, flowed—(5.) AQUA JULIA, from a source near that of the last-mentioned aqueduct to within 7000 paces of the walls of Rome, where the joint waters were received in a reservoir, and thence distributed in various channels to the city. Its entire length was 15,426 paces. It was constructed in the year 34 B.C. by Marcus Agrippa, to whose zeal to meet public wants in this direction were due the two other aqueducts—(6.) AQUA VIRGO, and (7.) AQUA CRABRA or DAMNATA, the former as well known for the goodness of its water as was the latter for the inferiority which procured it the designation of Damnata. The Aqua Virgo, from its origin at a copious spring in a marsh on the Collatine way, not far from the ancient Gabii, measured 14,105 paces, along which it was conveyed in pipes, partly under and partly above ground, on a solid substructure or on arches. It was completed in the year 48 B.C. (8.) AQUA ALSIETINA or AUGUSTA rose in Etruria, on the Via Claudia, and travelled 22,172 paces, of which 358 were on arches. It was the work of Augustus, whose object was to furnish by it water for gardens and other than drinking purposes. (9.) AQUA TRAJANA, rising in Lake Sabatinus (Bracciano), was constructed by Trajan. (10.) AQUA ALEXANDRINA, rising in the district of Tusculum, was the work of Alexander Severus. (11.) AQUA SEPTIMIANA seems to have been only a branch led from the Aqua Julia to supply the baths of the emperor from whom it takes its name, Septimius Severus. (12.) AQUA ALGENTINA rose on Mount Algidus; at whose instance it was made is unknown. Of the fourteen aqueducts which supplied ancient Rome, three remain in use at the present time, furnishing the modern city with abundance of water. The first of the three is the Aqua Virgo, now known as Fontana di Trevi, supplying the best water in Rome. It was restored by Pope Pius IV. The next is the Aqua Claudia, known as the Aqua Felice or di Termini, which was restored by Sixtus V. The third is the Aqua Trajana, called, from the Pope who restored it, viz., Paul V., Aqua Paole.

At regular intervals along the course of an aqueduct were built reservoirs (*castella*), to enable repairs to be made at any point, and also to let off water for the population of the district through which it passed. It was the law that material necessary for repairs should be supplied from the private property nearest to where the damage was, and should be conveyed at the cost of the owner of such property. *Castella* of smaller dimension were also required in many parts of the city. Of these, it was said, there were 247 in Rome. To allow the water to purify itself before being distributed in the city, large basins (*piscinæ limariæ*), were built outside the walls. For the process of purification salt was used (Vitruvius, viii.) These piscinæ were covered in with a vaulted roof, and were usually on a colossal scale, as in the example still preserved at Fermo, which consists of two stories, each having three oblong basins communicating with each other; or the Piscina Mirabile at Baiæ, which is covered in by a vaulted

roof, supported on forty-eight pillars, and perforated to permit the escape of foul air. Two stairs lead by forty steps to the bottom of the reservoir. In the middle of the basin is a sinking to collect the deposit of the water. The walls and pillars are coated with a stucco so hard as to resist a tool. The oversight of aqueducts was placed, in the times of the republic, under the ædiles and censors, though the latter appear to have taken part in work of this kind rather from their financial interest in the matter. Under the empire this task devolved on special officials styled *Curatores Aquarum*.

Among aqueducts outside of Italy, constructed in Roman times and existing still, the most remarkable, next to the Pont du Gard at Nismes already described, are—(1.) The aqueduct bridges at Segovia and Tarragona in Spain, the former being 2400 feet long, with 159 arches of greatly admired masonry, in two tiers, and reaching the height of 102 feet. The bridge at Tarragona is 876 feet long, and 83 feet high. (2.) At Mayence are the ruins of an aqueduct 16,000 feet long, and carried on from 500 to 600 pillars. Similar witnesses of Roman occupation are to be seen in Dacia, Africa, and Greece. (3.) The aqueduct at Metz (figured on Plate IV.), which originally extended across the Moselle, here very broad, conveyed to the city an abundance of excellent water from Gorsa. From a large reservoir at the source of the aqueduct the water passed along subterranean channels built of hewn stone, and sufficiently spacious for a man to walk in them upright. Similar channels received the water after it had crossed the Moselle by this bridge, at the distance of about 6 miles from Metz, and conveyed it to the city. The bridge consisted of only one row of arches. The middle arches have given way under the force of the river, but the others are still perfectly solid. (4.) On Plate III. is figured one of the principal bridges of the aqueduct of Antioch, 700 feet long, and at the deepest point 200 feet high. The lower part consists almost entirely of solid wall, and the upper part of a series of arches with very massive pillars. The masonry and design are rude. The water supply was drawn from several springs at a place called Battelma, about 4 or 5 miles from Antioch. From these separate springs the water was conducted by channels of hewn stone into a main channel, similarly constructed, which traversed the rest of the distance, being carried across streams and valleys by means of arches or bridges. (5.) At the village of Morea, about an hour's distance N.W. from the town of Mytilene, is the bridge of an aqueduct, figured on Plate III. The water-course is carried above massive pillars built of large hewn blocks of grey marble, and connected by means of three rows of arches, of which the uppermost is of brick. The bridge extended about 500 feet in length, and at the deepest was from 70 to 80 feet high. Judged by the masonry and the graceful design, it has been thought to be a work of the age of Augustus. Remains of this aqueduct are to be seen at Larisson Lamarousia, an hour's distance from Morea, and at St Demetri, two hours and a half from Ayasso, on the road to Vasilika.

The aqueduct near Spoleto, which now serves also as a bridge, is deserving of notice as an early instance of the use of the pointed arch, belonging as it does to the 7th or 8th century. It has ten arches, remarkable for the elegance of their design and the airy lightness of their proportions, each over 66 feet in span, and about 300 feet in height. (See Plate IV.)

The aqueduct of Pyrgos, near Constantinople (figured on Plate III.), is a remarkable example of works of this class carried out in the later times of the Roman empire. It consists of two branches, of which only one is seen in elevation on the plate. The other branch stood nearly at right angles to this, and is seen partly on the plan. From this circumstance it was called the Bended or Crooked Aqueduct, to distinguish it from another termed the Long Aqueduct, situated near the source of the waters. The branch seen in elevation extends 670 feet in length, and is 106 feet in height at the deepest part. It is composed of three rows of arches, those in each row increasing in width from the bottom to the top—an arrangement very properly introduced with the view of saving materials without diminishing the strength of the work. The two upper rows consisted of arches of semicircles, the lower of Gothic arches; and this circumstance serves to fix the date of the structure, as these last were not introduced until the 10th century. The breadth of the building at the base was 21 feet, and it diminished with a regular batter on each side to the top, where it was only 11 feet. The base also was protected by strong buttresses or counterforts, erected against each of the pillars. The other branch of the aqueduct was 300 feet long, and consisted of twelve semicircular arches.

This aqueduct serves to convey to Constantinople the waters of the valley of Belgrade, one of the principal sources from which the city is supplied. These are situated on the heights of Mount Hæmus, the extremity of the Balkan Mountains, which overhangs the Black Sea. The water rises about 15 miles from the city, and between 3 and 4 miles west of the village of Belgrade, in three sources, which run in three deep and very confined valleys. These unite a little below the village, and then are collected into a large reservoir. After flowing a mile or two from this reservoir, the waters are augmented by two other streams, and conveyed by a channel of stone to the Crooked Aqueduct. From this they are conveyed to another which is the Long Aqueduct; and then, with various accessions, into a third, termed the Aqueduct of Justinian. From this they enter a vaulted conduit, which skirts the hills on the left side of the valley, and crosses a broad valley 2 miles below the Aqueduct of Justinian, by means of an aqueduct, with a double row of arcades of a very beautiful construction. The conduit then proceeds onward in a circuitous route, till it reaches the reservoir of Egri Kapan, situated just without and on the walls of the city. From this the water is conducted to the various quarters of the city, and also to the reservoir of St Sophia, which supplies the seraglio of the grand signior. The Long Aqueduct is more imposing by its extent than the Crooked one, but is far inferior in the regularity of design and disposition of the materials. It is evidently a work of the Turks. It consists of two rows of arcades, the lower being forty-eight in number, and the upper fifty. The whole length was about 2200 feet, and the height 80 feet. The Aqueduct of Justinian is a very excellent work, and without doubt one of the finest monuments which remain to us of the Middle Ages. It consists of two rows of large arcades in the pointed style, with four arches in each. Those of the lower story have 52 feet of span, the upper ones 40 feet. The piers are supported by strong buttresses, and at different heights they have little arches passing through them, which relieve the deadness of the solid pillar. The length of this aqueduct is 720 feet, and the height 109 feet. This aqueduct, though it bears the name of Justinian, was probably erected in the time of Constantine.

Besides the waters of Belgrade, Constantinople was supplied from several other principal sources, one of which took its rise on the heights of the same mountains, 3 or 4 miles east of Belgrade. This was conveyed in a similar manner by an arched channel, elevated, when it was necessary, on aqueduct bridges, till it reached the northern parts of the city. It was in the course of this aqueduct that the contrivance of the *souterasi* or hydraulic obelisks, described by Andreossy (in his voyage to the Black Sea and account of the Thracian Bosphorus) was constructed, which excited some attention, as being an improvement on the method of conducting water by aqueduct bridges. "The souterasi," says Andreossy, "are masses of masonry, having generally the form of a truncated pyramid or an Egyptian obelisk. To form a conduit with souterasi, we choose sources of water, the level of which is several feet higher than the reservoir by which it is to be distributed over the city. We bring the water from its sources in subterranean canals, slightly declining until we come to the borders of a valley or broken ground. We there raise on each side a souterasi, to which we adapt vertically leaden pipes of determinate diameters, placed parallel to the two opposite sides of the building. These pipes are disjoined at the upper part of the obelisk, which forms a sort of basin, with which the pipes are connected. The one permits the water to rise to the level from whence it had descended; by the other, the water descends from this level to the foot of the souterasi, where it enters another canal under ground, which conducts it to a second and to a third souterasi, where it rises and again descends, as at the last station. Here a reservoir receives it and distributes it in different directions by orifices of which the discharge is known." Again he says, "it requires but little attention to perceive that this system of conducting tubes is nothing but a series of syphons open at their upper part, and communicating with each other. The expense of a conduit by souterasi is estimated at only one-fifth of that of an aqueduct with arcades." There seems to be really no advantage in these pyramids, further than as they serve the purpose of discharging the air which collects in the pipes. They are in themselves an evident obstruction, and the water would flow more freely without any interruption of the kind. In regard to the leaden pipes, again, they would have required, with so little head pressure as is stated, to be used of very extraordinary dimensions to pass the same quantity of water as was discharged along the arched conduits. There is something, therefore, which would require explanation in the account Andreossy gives of these pyramids, if, indeed, he did not misunderstand the nature of them.

The other principal source from which Constantinople is supplied, is from the high grounds 6 or 8 miles west of the town, from which it is conducted by conduits and arches, in the same manner as the others. The supply drawn from all these sources, as detailed by Andreossy, amounted to 400,000 cubic feet per day. The charge of the water-works at Constantinople belongs to a body of 300 Turks and 100 Albanese Greeks, who form almost an hereditary profession.

In ancient Egypt and Babylonia a different problem of water supply was presented, both countries being flat and traversed by great rivers, from which they were subject to regular inundations. Hence canals with large basins took the place of the aqueducts of Greece and Rome, and the stupendous scale on which in Egypt the waters of the Nile, and in Babylonia the waters of the Tigris and Euphrates, were utilised, was a marvel to ancient travellers.

In France various aqueducts have been formed after the manner of the Romans. The most remarkable are those constructed in the reign of Louis XIV., at vast expense, for conducting water from Marly to Versailles. The famous aqueduct bridge of Maintenon, which was erected for conveying the waters of the river Eure to Versailles, is without doubt, in point of magnitude and height, the most magnificent structure of the kind in the world. In Plate IV. a view is given of a portion of this work, on the same scale as the others there represented. Had the whole been delineated on the same scale, it would have extended to four times the breadth of the plate. It extends about 4400 feet in length, that is, about five-sixths of a mile, is upwards of 200 feet in height, and contains 242 arcades, each divided into three rows, forming in all 726 arches about 50 feet span. Of the subterranean aqueducts in France the finest is that of Arcueil, which serves to conduct water to that village. It is 44,300 feet in length, or upwards of 8 miles, extending from the valley of Arcueil to the castle at the gate of St Jaques, all built of hewn stone. It is about 6 feet in height, and has on each side a foot-path 18 inches wide; it has a declivity of 1 foot in 1300. Another aqueduct of this kind is that of Rocquancourt, part of the system which brings water to Versailles; it is 11,760 feet in length, or upwards of 2 miles, and has a declivity in its whole course of only 3 feet. In some parts of its course it was necessary to make excavations 80 or 90 feet deep, which rendered the execution very difficult.

The great waterworks that supply the city of Marseilles with the water of the Durance, by a canal about 60 miles in length, are among the boldest undertakings of the kind in modern times. This canal, begun in 1839, and completed in 1847, is conveyed through three chains of limestone mountains by forty-five tunnels, forming an aggregate length of 8½ miles, and across numerous valleys by aqueducts; the largest of which, the Aqueduct of Roquefavour, over the ravine of the River Arc, about 5 miles from Aix, surpasses in size and altitude the ancient Pont du Gard. The immense volume of water, which passes at the rate of 198,000 gallons per minute, is carried across as in the old Roman aqueducts by a channel of masonwork. The height of this aqueduct is 262 feet, and its length 1287.

One other aqueduct of modern construction is worthy of notice. In those parts of British India where the fall of rain is scanty and uncertain, recourse is had to artificial irrigation, and the waters of many of the rivers of the country have been rendered available for this purpose by means of public works constructed by the Government. Of these the most important is the Ganges Canal, which traverses the North-Western Provinces of Bengal, and distributes over their vast area nearly the whole volume of the waters of the Ganges. The canal begins at the point where the river issues from the mountains, and enters the plains of Bengal. About 20 miles from its source, the line of the canal crosses the valley of the Solani river, and the works for effecting the transit are designed on a scale worthy of the undertaking. The valley is between 2 and 3 miles in width. An earthen embankment is carried across, raised on an average between 16 and 17 feet above the surrounding country, and having a width of 350 feet at its base, and 290 feet in the upper part. This embankment forms the bed of the canal, which is protected by banks 12 feet in depth, and 30 feet wide at the top. To preserve these banks from the effects of the action of the water, lines of masonry formed into steps extend on each side throughout their entire length. The Solani river is crossed by an aqueduct 920 feet long, having side walls 8 feet thick and 12 deep, the depth of the water being 10 feet. The water of the canal passes through two separate channels. That of the River Solani flows under fifteen arches, having a span of 50 feet each, constructed in the most substantial manner, and springing from piers resting on blocks of masonry sunk into the bed of the river. The cost of the aqueduct was upwards of £160,000. In grandeur of design, solidity of construction, and, above all, in extensive utility, it may challenge competition with any similar work in the world.

Within the last century, the invention and improvement of the manufacture of cast iron has completely changed the mode of conducting water into cities, by the introduction of cast-iron pipes instead of the stone conduits of former times. These pipes can now be formed of almost any dimensions, and united together into a continued series so closely as to prevent the escape of the water even under a violent pressure, arising from the altitude of the fountainhead. They enable us, therefore, to take advantage of and give effect to the fundamental principle of hydrostatics, that the fluid tends continually to a level, even though it be confined in the smallest or most complicated system of pipes; so that however low it be carried in any valley, or to whatever distance, still it will rise on the opposite side to the original altitude of the fountainhead—a principle which is most important indeed in such works, seeing that by it we are not restricted, as the Romans were, almost to a perfect level in the line of the conduit. We have seen that, for the purpose of attaining this level or very gentle declivity all along the conduit, they were under the necessity of raising it by arcades continued in one unbroken series, frequently 30 or 40 miles in extent; and, in addition to this, they had often to prolong the length of the track by a circuitous route, turning and winding for miles out of its course, for the very purpose of increasing its length.

But the use of pipes enables us to dispense with these long arcades all raised nearly to the same level with the fountainhead; because the conduit may be varied in its level to any extent, and still will rise at last to its original altitude. The pipes, therefore, are merely laid all along the surface of the ground, with a cover of 2 or 3 feet of soil to place them beyond the reach of frost. To prevent, however, the frequent or abrupt alternations of rise and fall, any sudden inequalities in the ground are equalised by cuttings and embankments, but not to anything like the extent that would be required to raise the whole to a level. This, therefore, forms a very great improvement in the method of conducting water, the greatest indeed which has ever been made in this important branch of practical mechanics. That it was not introduced by the Romans, is not to be ascribed, as many have supposed, to their ignorance of the hydrostatic principle that the fluid would rise to a level in the opposite branches of the same train of pipes. They were well acquainted with this principle, and a portion of a leaden pipe, supposed to have been used in the baths of Caracalla, has been found, which sets this matter at rest; but, from the low state of the arts at that period, they were unable to give effect to the principle. They had not the means of fabricating pipes of such a magnitude as would have been required for the enormous quantities of water consumed in Rome, and at the same time, of strength sufficient to withstand the pressure from the fountainhead. Lead was the only material that could be used by them for the purpose; and besides the enormous thickness that so weak a material would have required, and the impracticability of their forming pipes, and uniting them together endwise, they were too well acquainted with the tendency of lead to render the water unwholesome by its poisonous impregnation. The use of cast iron was quite unknown. There remained, therefore, no resource but in the aqueducts, which, though attended no doubt with vast expense, and requiring great enterprise, skill, and patience, were yet attainable by these means, and formed when completed a simple and very perfect mode of effecting the object. Now, however, when the manufacture of cast iron has been brought to such perfection, and methods contrived for uniting perfectly together all the pipes into one connected train, this improved system has been universally adopted.

In former editions of this work (under this heading) the works of the Edinburgh Water Company, undertaken in 1819, and designed by Mr Jardine, civil engineer, were described; but as there is little which can properly come under the popular definition of Aqueduct, they will be more consistently referred to in the article WATERWORKS.

Croton Aqueduct, New York.

The Croton Aqueduct, by which the city of New York is supplied with water, was justly regarded at the time of its execution, from 1837 to 1842, as one of the most magnificent works of the kind in modern times (figs. 1 to 5).

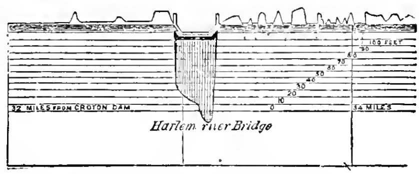

FIG. 1.—Part Section of Croton Waterworks.

Its length from the Croton Lake to the receiving reservoir is $38\frac{1}{4}$ miles. The original reservoir, called Croton Lake, is formed by an embankment across the Croton Creek, a small stream of wholesome water falling into the Hudson. It covered 400 acres, and contained about 500,000,000 gallons of water. To the valley of the Harlem River, a distance of 33 miles, the aqueduct (fig. 2,) is built of stone, brick, and cement, arched over and under, 6 feet 3 inches wide at the bottom, 7 feet 8 inches at the top, and 8 feet 5 inches high, and capable of discharging 60,000,000 gallons per day. It is carried over the Harlem Valley in iron pipes, laid upon a magnificent bridge (figs. 3 and 4) 1460 feet long, constructed of arches 114 feet above

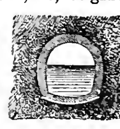

FIG. 2.—Tunnel in soft ground.

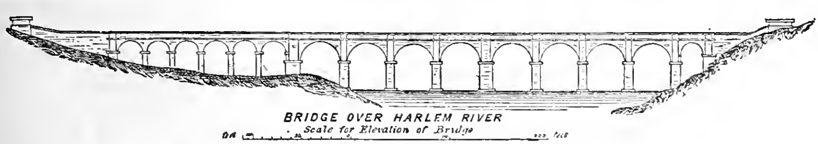

Fig. 3.

high-water mark at Yorkville. These pipes passed into a receiving reservoir capable of holding 150,000,000 gallons, and from thence the water was conducted for $2\frac{1}{2}$ miles to a distributing reservoir, containing 20,000,000 gallons, by a double line of iron pipes, 3 feet in diameter. From this reservoir the water was distributed to the city.

The Croton water was originally introduced into New York in 1842, when the population was about 450 000 persons, and from that time to 1848, 18,000,000 gallons per day gave an abundant supply. In 1872, with a population of 1,000,000 persons, the quantity required was 88,000,000 gallons per day. Thus, between 1848 and 1872, while the population little more than doubled, the consumption of water increased nearly five times. This fact, coupled with severe droughts in 1870 and 1871, when the natural volume of the Croton River fell to 27,000,000 gallons per day, caused great anxiety, and shewed the necessity of largely extended works. It was estimated that the basin above the Croton Dam, 339 square miles in area, would give 300,000,000 gallons per day on the average, if the water could be impounded, and that, therefore, abundant water could be obtained by increasing the number or capacity of the impounding reservoirs. New reservoirs were therefore projected, one of which, to contain 3,000,000,000 gallons, was expected to be completed in the autumn of 1872. With this the gross storage would be 4,670,000,000 gallons, in addition to the daily produce of the Croton River, which, at its minimum as stated, is 27,000,000 gallons per day. Another reservoir to contain 3,700,000,000 gallons was also projected, and will, it is presumed, be constructed when necessary (fig. 5). To meet the growing demand for water, the reservoirs were not only increased as described, but the means of distribution were largely extended, and in one part of the city six lines of pipes 4 feet in diameter were laid side by side.

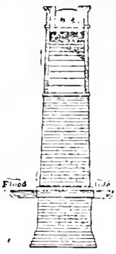

Fig. 4.—Cross section of bridge.

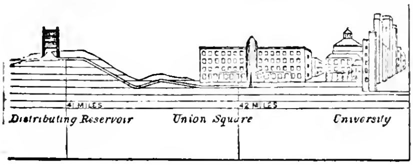

Fig. 5.—Part section of Croton Waterworks.

Manchester Waterworks.

The works by which the city of Manchester and its suburbs are now supplied with water, and which have been in course of construction from the year 1848 to the present time (1874), are perhaps, in some respects, the most stupendous works of the kind which have ever been constructed, in which difficulties of no ordinary character have been successfully overcome. These remarks, however, relate especially to the impounding reservoirs, which are seven in number, with embankments varying from 70 to 100 feet above the level of the valley in which they are constructed, and cannot, therefore, be properly alluded to here. As the conveyance of the water to the city is, however, by aqueduct, a few words explanatory of the general scheme will be necessary.

The water is collected from the river Etherow and its tributaries, which, rising on the westerly slope of the Pennine chain of hills, flow into the river Mersey, and so into the Irish Sea. The drainage ground from which the water is collected lies nearly midway between Manchester and Sheffield. Its area is about 19,300 acres. It rises in parts to an elevation of about 1800 feet above the level of the sea, and about 1200 or 1300 feet above the deep and romantic valley of Longdendale, in which the main collecting reservoirs are situated. The district consists of the shales and sandstones which constitute the lower portion of the Coal Measure formation—the upper millstone grit forming the cap of the steep escarpments on each side of the valley, while the lower millstone grit, which may be said to separate the Coal Measure shale from the limestone shale, is found in the bottom. The waters produced by this geological formation are among the purest in the world. The spring water is especially brilliant, highly aerated, containing little or no foreign matter, and extremely soft. It is at all times very abundant, the district yielding much more spring water than the usual quantity, in proportion to the area from which the springs issue. The quantity of water flowing from the drainage ground would, if wholly stored, afford a gross supply of about 40,000,000 gallons per day, of which about 13,000,000 gallons per day have to be delivered as compensation to the mills on the stream, leaving about 27,000,000 gallons per day as the supply available for the city and its suburbs.

The water of heavy rains and wet seasons is collected in large impounding reservoirs, the gross capacity of which is 4,233,000,000 gallons. In some of these reservoirs the turbid and coloured water is impounded, where it is allowed to settle and purify, and is subsequently given as compensation to the stream; and in others, the pure water, when more than sufficient for the wants of the city, is collected. Here it is stored till required, and then given in addition to the spring water, when that is in itself deficient in quantity. The spring water is separately collected, and conveyed to the city by aqueducts specially constructed for the purpose. In heavy rains, which swell the streams, and especially in autumn, the water is discoloured, but by a simple and ingenious contrivance, every stream is made to separate its coloured water from its pure water—the coloured water being passed to reservoirs set apart for the storage of such water, and the pure water being sent at once to Manchester, or passed to reservoirs in which it is stored for future use.

The aqueducts by which this water is conveyed from the springs and from the reservoirs, consist for the most part of tunnel and covered conduit, 6 feet in diameter, with a fall of 5 feet in a mile, with cast-iron syphon pipes of large dimensions across one valley, which has to be passed before the highest service reservoir is reached. From this reservoir to the city, about 8 miles distant, cast-iron pipes are laid along or under the public roads, to convey the water to various other reservoirs at lower elevations, from which the city and its suburbs are conveniently supplied.

In the main valleys in which the spring water is collected, or the flood and turbid waters conveyed by separate channels, the aqueducts are chiefly open, and are, to a great extent, formed of concrete 6 inches thick on the sides and bottom, faced with dry stone pitching 9 inches in thickness. They are cheap, easily constructed, and perfectly successful.

The area and capacities of all the reservoirs are as follows:—

Name.	Area.	Capacity.	Depth.
	Acres.	Gallons.	Feet.

Loch Katrine Aqueduct, Glasgow.

The Loch Katrine Aqueduct of the Glasgow Waterworks is the modern aqueduct which has most probably attracted the largest share of public attention.

The appropriation of the beautiful waters of Loch Katrine—rendered classical by Sir Walter Scott—the romantic, rugged, and almost impassable Highland country through which the aqueduct had to be constructed, and the distance from Loch Katrine to Glasgow, all contributed to lend a special interest to the undertaking. It is, however, a very simple work in itself, for, with but little artificial addition, Loch Katrine, Loch Venachar, and Loch Drunkie were converted into impounding reservoirs, the first for the supply of the city, and the two latter for compensation.

The area and capacity of these reservoirs are as follows:—

	Area at Summer Level.	Extent to which Lochs can be raised or lowered.	Height of raised Level above ordnance datum.	Capacity	Drainage Area.	Proportion of Storage to each Acre of Drainage Area.
	Acres.	ft. in.	Feet.	Gallons.	Acres.	Gallons.

Totals,	3,948			9,093,750,000	45,800	

The length of the aqueduct from Loch Katrine to Glasgow is about 35 miles, of which 27 may be considered as the aqueduct proper The remaining 8 consist of two lines of cast-iron pipes, by which the water is conveyed from the large service reservoir at Mugdock to the city of Glasgow. The aqueduct is principally in tunnel or covered conduit, but there are three valleys which are crossed by iron syphon pipes of large diameter, and there are numerous aqueduct bridges of varied character, suited to the peculiarities of the districts in which they had to be constructed. The tunnels and covered conduits are 8 feet high and 8 feet wide, with an inclination of 10 inches in a mile, and are capable of conveying about 50,000,000 gallons of water in twenty-four hours. The syphon pipes across the valleys have an inclination of 1 in 1000, or about 5 feet in a mile, and it requires two pipes of 4 feet in diameter and one of 3 feet in diameter, to convey the quantity of water in a day which the aqueduct will deliver.

The work required the greatest engineering accuracy and skill, and so perfectly have the lines and levels been kept, that it was only upon the closest examination that the joinings in the tunnels could be detected.

The work was commenced in the spring of 1855, opened by her Majesty the Queen in October 1859, and finally completed in the course of 1860.

The cost of the engineering works of the aqueduct, including the conversion of the various lochs mentioned into reservoirs, and exclusive of land, and of the distribution of the water in the city of Glasgow and its neighbourhood, was £668,000; but the gross cost of the water supply, including the purchase of two water companies, distribution, and everything, has been, to May 1873, £1,756,793.

The following description of the aqueduct was given by the engineer at a banquet given to him in Glasgow after the completion of the works:—

"It is impossible to convey to those who have not personally inspected it, an impression of the intricacy of the wild and beautiful district through which the aqueduct passes for the first 10 or 11 miles after leaving Loch Katrine. From the narrowest point at which it was found the ridge between Loch Katrine and Loch Chon could be pierced, the country consists of successive ridges of the most obdurate rock, separated by deep wild valleys, in which it was very difficult in the first instance to find a way. There were no roads, no houses, no building materials,—nothing which would ordinarily be considered essential to the successful completion of a great engineering work for the conveyance of water; but it was a consideration of the geological character of the material, which gave all the romantic wildness to the district, that at once determined me to adopt that particular mode of construction which has been so successfully carried out. For the first 10 miles, the rock consists of mica schist and clay slate—close, retentive material, into which no water percolates, and in which, consequently, few springs are to be found. This rock, when quarried, was unfit for building purposes; there was no stone of a suitable description to be had at any reasonable cost or distance, no lime for mortar, no clay for puddle, and no roads to convey material. Ordinary surface construction, therefore, was out of the question; but I saw that if tunnelling were boldly resorted to, there would be no difficulty, beyond the cost and time required in blasting the rocks, in making a perfectly watertight and all-enduring aqueduct; there would be no water to hamper and delay us in the shafts and tunnels, and little would require transporting through the country but gunpowder and drill iron. This course was therefore determined upon, and my expectations have been realised to the very letter. The aqueduct may be considered as one continuous tunnel. As long as the work continued in the primary geological measures, we had no water; and even after it entered the Old Red Sandstone, and where it subsequently passed through trap rock, there was much less than I expected; so that our progress, at no part of the work, was ever materially interfered with by those incidents which usually render mining operations costly and uncertain."

The rock, however, especially the mica slate, proved extremely hard and difficult to work. At several points along the side of Loch Chon the progress did not exceed 3 or 4 lineal yards in a month at each face, although the work was carried on day and night. The average progress through the mica slate was about 5 yards in a month. In drilling the holes for blasting, a fresh drill was required for every inch in depth on the average, and about sixty drills were constantly in use at each face. The cost of the gunpowder alone, consumed in the first $7\frac{1}{2}$ miles of the aqueduct, was £10,540, and there were about 175 miles of fuse burned in firing it. The average cost per yard of this length of the aqueduct was over £13, or £23,000 per mile. (Figs. 6 to 11, are cross sections of the aqueduct, showing the general construction in various kinds of ground.) The built and tunnelled part is all capable of passing 50,000,000 gallons per day.

The aqueduct bridges over the ravines are somewhat peculiar, varying in character according to the circumstances of the district. In the wilder and more inaccessible parts there are five extensive iron ones, varying in length from 124 to 332 yards, all of similar construction. (See fig. 12.) At the ends of these bridges, in the shallowest parts of the ravines, the aqueduct has a cast-iron trough supported on a solid dry stone embankment of the stone of the district, carefully set by hand; the stone embankment being 9 feet wide at top, with a batter of 3 inches to the foot on each side. The deeper parts of the ravines or valleys are crossed by malleable iron tubes 8 feet wide by $6\frac{1}{2}$ feet high inside, supported by piers at intervals of 50 feet. The bottoms and sides of these tubes are ⅜ inch thick, and the tops $\frac{7}{16}$ inch thick, strengthened by angle and T iron. Fig. 13 shows a section of these tubes. The cast-iron troughs (fig. 14) are 8 feet broad and 4 feet deep, and ⅝ inch thick, and were capable of passing at this depth upwards of 20,000,000 gallons a day. Provision was

made for adding 2½ feet to the height of the sides when additional water was required, and this has since been done. The bottoms of the malleable-iron tubes are 3 feet below

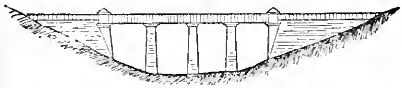

Fig. 12.—Iron Aqueducts at Culegarton.

the bottoms of the troughs, so that they should always be full of water, for the purpose of securing the same temperature both in the bottom and top of the tubes, and so pre-

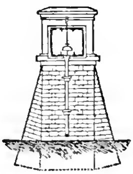

Fig. 13.—Section through Iron Tube.

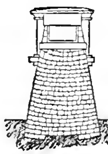

Fig. 14.—Section through Cast-iron Trough.

venting unequal expansion and contraction. The aqueduct at the crossing of small mountain streams (of which there were many) was carried in cast-iron troughs similar to those already described, supported upon cast-iron beams over the space left for the stream.

The first deep valley which required to be crossed by piping is that of the Duchray water, about 55 chains wide. The pipes first laid down were 4 feet diameter in 9 feet lengths, with spigot and faucet joints, run up with lead in the usual way. At the lowest point the pipes are under a pressure of 165 feet. The river itself is crossed by cast-iron arched girders of 60 feet span; and here, as well as at the small basins at each end of the piping, and at all other places where masonry was required, provision was made for laying two additional lines of pipes, one 4 feet and the other 3 feet in diameter. These pipes have since been laid. After passing through the ridge of Old Red Sandstone conglomerate by the Clashmore tunnel, the aqueduct for 5 miles is for the greater part in open cutting, with masonry sides, and a dry rubble arch covered with 2 feet of puddle, and then covered in.

The Endrick valley, like that of the Duchray, is crossed by cast-iron syphon pipes for 2¼ miles in length. Where they cross the river Endrick at the bottom of the valley, the pipes are 1⅝ inches thick, and have to sustain a pressure of 238 feet. The pipes are carried across small depressions in the valley by resting them upon stone piers, and at the crossing of two roads, and of the Forth and Clyde railway, they are further supported by cast-iron brackets. The pipes at these exposed places have flange joints, and they have been covered with woollen felt to prevent expansion and contraction. There is a short tunnel 110 yards long on this length of piping of dimensions sufficient to carry the three lines of pipes. The construction of the aqueduct, for the 5 miles extending from the valley of the Endrick to the valley of the Blane, presents the same general features as those already described. Good building stone was abundant in this district, and the bridges are all

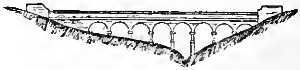

Fig. 15.—Duntreath Aqueduct.

of masonry. Fig. 15 is an elevation of one of the aqueduct bridges near Killearn at 19 miles from Loch Katrine;

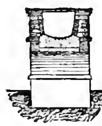

Fig. 16.—Section through Arch.

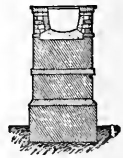

Fig. 17.—Section through Pier.

and figs. 16 and 17 are details of the Ballewan Aqueduct bridge (fig. 18)

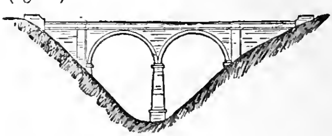

Fig. 18.—Ballewan Aqueduct.

The piping across the Blane is about 54 chains long, with a depression of 125 feet. The Blane water itself is crossed by a stone bridge, and there are basins at each end of the pipes as before. The last piece of the aqueduct is a tunnel 2640 yards long, through a ridge of amygdaloidal trap, separating the valley of the Blane from the valley of the Allander. The tunnel is 250 feet below the summit of the hill.

Mr Bateman, at the banquet referred to, summarised the works along the line of aqueduct in nearly the following words:—"There are in the whole work eighty distinct tunnels, upon which forty-four vertical shafts have been sunk for facilitating and expediting the completion of the work." Besides the tunnel at the commencement of the aqueduct, called the Loch Katrine Tunnel, 2325 yards in length, and upwards of 500 feet below the summit of the hill, and the Mugdock Tunnel at the end of the aqueduct, 2640 yards in length, there are "others, 700, 800, 1100, and 1400 yards in length. Not to speak of smaller constructions, there are twenty-five important iron and masonry aqueducts over rivers and ravines, some 60 and 80 feet in height, with arches of 30 feet, 50 feet, and 90 feet in span. The number of people employed, exclusive of iron-founders

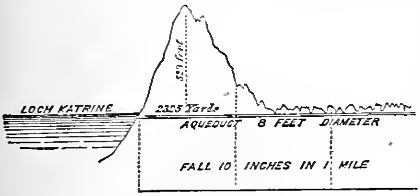

FIG. 19.—Part Section of Loch Katrine Aqueduct.

and mechanics, has generally been about 3000; and for the greater part of these, huts and roads and all other accommodation had to be provided, the country for the most part being of the wildest and most inaccessible description."— . . . . . "At the picturesque, 'turf and timber' village of Sebastopol, as the miners called it, at the head of Loch Chon, several hundreds of work-people were accommodated. Provision stores, reading-rooms, a school-house and church, and a resident medical man and school-master were provided for them."

The aqueduct from its commencement at Loch Katrine to the Mugdock reservoir, is 25¾ miles long, 13 of which were tunnelled, 3¾ miles are iron piping across valleys, and the remaining 9 miles consist of "cut and cover" conduit and bridges. Where the ground was cut open the conduit was covered in, and the surface restored after the aqueduct was built. At the bridges the aqueduct is covered with timber to prevent its being choked by snow. Most of them are furnished with grooves in the masonry to receive stop planks, and with discharge sluices to facilitate the emptying of the aqueduct, when it is necessary to inspect or make repairs. Overflows are constructed at a number of the bridges, to discharge the water if it should be necessary to stop the flow suddenly at any point. The total cost of the aqueduct at the time the water was introduced into the city, was £468,000, or an average of £18,000 per mile.

It has been already stated that the 4-feet pipes across the valleys on the line of aqueduct were intended to deliver 20,000,000 gallons a day. By the well-known modification of Eytelwein's formula, deduced from Du Buat's experiments and more elaborate formulæ, the computed discharge is 21,500,000 gallons a day nearly, and by Weisbach's formulæ, 21,750,000 gallons a day. These pipes, however, have discharged 24,000,000 gallons a day without their being completely gorged, and their ultimate discharge has therefore yet to be determined. The whole of the pipes used in the works were coated with coal pitch and oil, according to the process patented by Dr R. A. Smith of Manchester, and first used by Mr Bateman in the Manchester Waterworks. This coating, when well done, imparts a smooth glassy surface to the pipes, and prevents, at least for a number of years, the usual, and it may be said, inevitable oxidation. Weisbach found that for wooden pipes 2½ and 4½ inches diameter, the coefficient of resistance was 1·75 times as great as for "metallic pipes," giving a discharge about 14 per cent. less; and M. Morin has shown, in a paper which it is believed is published in detail in the *Mémoires des Savants Etrangers*, the influence the state of the surface has upon the discharge of a pipe, amounting, in cast-iron pipes coated with pitch, and in glass pipes, to an increase of nearly one-third in the discharge.

It has also been pointed out by M. Morin, whose deductions are principally from observations by M. Darcy, director of the waterworks of Paris, that for large sizes the diameters of the pipes seem also to exercise a more decided influence on the discharge than has been hitherto assigned to them. Late observations on the flow of gas through pipes by M. Arson, engineer of the Paris Gas Company, tend to confirm the views of M. Morin.

At the Mugdock Service Reservoir, 7 or 8 miles from Glasgow, the water is first discharged into a basin, from which it passes over cast-iron gauge plates, 40 feet wide, brought to a thin edge. The depth of water passing over these plates is regularly recorded and the discharge computed. From the basin the water falls into an upper division of the main reservoir, about 2 acres in extent, and from this it is discharged into the reservoir. The reservoir has a water surface of 60 acres, and a depth when full of 50 feet; it contains 548,000,000 gallons, and is 317 feet above ordnance datum. It admits of repairs being made upon the aqueduct without interrupting the supply of water to the city. Two earthen embankments were necessary to form the reservoir; the main embankment is 400 yards long and 68 feet high, and the easterly embankment 240 yards long and 50 feet high, each with a puddle wall in the centre, and pitching on the front slope in the usual way.

The water is drawn from the reservoir by pipes laid in a tunnel through the hill between the two embankments, there being no pipes through the embankments themselves.

At the end next the reservoir there is a stand-pipe so arranged that water can be drawn at various heights, and about 50 yards from the reservoir, the water passes into a circular well cut out of the rock, 40 feet in diameter and 63 feet deep, and is strained by passing through copper wire-cloth, 40 meshes to the inch, arranged in oak frames, forming an inner well of octagonal shape 25 feet diameter; and from this latter the water finally passes into the two lines of pipes leading to the city. Water can also be drawn direct from the gauge basin, and from the upper compartment of the reservoir into the straining well, by a line of 4-feet pipes through the bottom of the reservoir. These works, including road and stream diversions, cost about £56,000.

The two pipes leading from the straining well are each 42 inches diameter, and are intended to deliver the whole 50,000,000 gallons a day; but on emerging from the tunnel, which is 440 yards in length, they are diminished to 36 inches, and they are continued of this size to the city. Provision was made for additional pipes, which have since been laid. The different lines of pipes are laid side by side for about 3 miles, after which they diverge—one line being carried by the Great Western Road for the supply of the low districts of the city, and the other by Maryhill for the supply of the high districts. These pipes come together again, and are arranged so as to communicate when necessary at St George's Road near the commencement of the city, up to which point their respective lengths from the straining well are 7 miles for the low district main, and 6½ miles for the high. Each of these lines of pipes crosses the River Kelvin and the Forth and Clyde Canal, and at these places provision was made for additional pipes. Eleven feet were added to the width of the Kelvin Bridge on the Great Western Road, by cast-iron girders, to carry the low district mains. The two middle spans are each 93 feet, and the two side arches 37 feet span.

The total cost of the works at their completion, in 1860, was as follows:—

Work at the Lochs, ...	£ 36,000	
Aqueduct, 25¾ miles long, ...	468,000

		157,000
Total, ...		£918,000

Vienna Waterworks.

A still more recent work, consisting mainly of aqueduct construction, is the enterprise for supplying the city of Vienna with water. The water is obtained from the springs of Kaiserbrunn and Stixenstein, both situated at the foot of the Styrian Alps, which separate Austria from Styria. The Kaiserbrunn spring is situated 1146 English feet above the Danube at Vienna, and the Stixenstein spring 996 feet. The water is conducted by aqueduct to a receiving reservoir at Rosenhugel, 277 feet above the Danube, and distant 2 miles from Vienna. The length of the aqueduct from Kaiserbrunn to the receiving reservoir on the Rosenhugel, is 56½ English miles. A branch of 3·9 English miles conducts the Stixenstein spring to this aqueduct. The gradients of the aqueduct vary much in the upper or early parts; but towards the end they become more regular. The gradients have been thus varied for the purpose of keeping the canal as much as possible along the level of the ground, so as to avoid high embankments. In order to keep the water cool in summer, and to secure it from freezing in winter, the water is always 6 feet below the surface; and in places where embankments were unavoidable, the aqueduct has been covered to the same extent. The size of the aqueduct varies from 4 feet 6 inches in height, by 2 feet 6 inches in width, to 6 feet 6 inches in height, by 4 feet in width. In order to facilitate the discharge, and to reduce friction, the inside of the aqueduct has been plastered with a coating 2 inches thick of Portland cement and sand, in the proportion of one of cement to two of sand. This coating was laid on in three layers, the last being a very thin layer of pure cement, which, when hardened, was rubbed with iron plates till it became perfectly smooth and polished. The work was commenced in the winter of 1869-70, and completed in the month of September 1873. The aqueduct is constructed for the purpose of supplying about 3,200,000 cubic feet per day, or 20,000,000 gallons. There are

FIG. 20.—Baden Bridge, Vienna Waterworks (7 out of 43 arches).

several important aqueduct bridges along the line of works. Of these the principal is the aqueduct of Baden, which consists of forty-three large arches, with spans varying from 5 klafters to 8½ klafters, and the greatest height 15 klafters 5 feet 5 inches, or 96·6 English feet, from the foundation of the pier to the top of the aqueduct. The arches are of brickwork, as well as the vaulting of the canal. The piers, together with the backing of arches and the sides of the canal, are faced with ashlar, and filled up with rubble masonry. The canal is covered on the top with earth, which is then covered with 9 inches of paving in rubble masonry

The Mödling Aqueduct is, although one of the shortest, perhaps the finest on the whole line of the works. It is situated in a very narrow gorge, with high rocks rising on the side. The canal or aqueduct passes through a tunnel on one side, and after crossing the aqueduct enters imme-

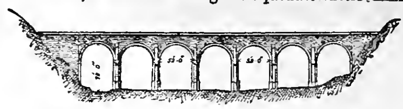

FIG. 21.—Mödling Bridge, Vienna Waterworks.

diately into another tunnel on the other. This aqueduct bridge consists of spans of 9 klafters, or 55·98 English feet, in width, and is built entirely of bricks, with the exception that the piers are pointed with ashlar. The abutments, the foundations of which are excavated in the rock, are built of rubble masonry, faced with ashlar. The other chief aqueducts are—the one at Liesing with forty-six arches, very similar to that of Baden, and that of Mauer with thirteen arches, built of bricks, and making a fine curve across the valley.

The receiving reservoir on the Rosenhugel, where the aqueduct ends, is divided into two parts, capable together of holding 80,000 cubic feet English. From this reservoir the water is taken to two other distributing reservoirs, from which the city is supplied. The cost of the work, together with the network of pipes in Vienna, has been about 25,000,000 florins or £2,000,000 sterling. The chief engineer of the work was Herr Carl Junker of Vienna, and the contractor Mr Antonio Gabrielli of London. The works were completed and opened in the autumn of 1873.

Water Supply of Paris.

The question of improving the water supply of this city was the subject of minute and careful investigations, extending over a period of four or five years, (from 1854 to 1859.)

Many projects were submitted to the Prefecture of the Seine, but the one finally adopted was that studied by Mr Belgrand and the engineers of the municipality of Paris. The scheme consisted in appropriating the waters of the Sonne and the Soude, together with the Soudon and the Dhuis, all being tributaries of the Marne, and flowing through chalk districts.

The population of Paris, for the supply of which the scheme was laid out, was taken at 2,000,000, and the waters from the sources selected were intended for the domestic supply only—the existing supplies to Paris, which have become gradually polluted and unfit for domestic use, being made available for all the other general wants of the population. The quantity of water which it was estimated would be required for the domestic purposes of such a population was taken at 100,000 cubic metres per diem, or about 22,000,000 gallons per day; and the works have been laid out for conveying this quantity. Gaugings of the various streams selected, showed that in 1855, when the flow was at the lowest, the produce of the Sonne and the Soude was 1081 litres per second, the Soudon 100, the Dhuis 315; making a total of 1496 litres per second, or about 28,000,000 gallons per day. At the time of lowest water in 1857, however, the Sonne and the Soude together only yielded 880 litres per second, or 16,762,000 gallons per day, while in 1858, which was an exceptionally dry year (indeed the driest year on record in this locality), they yielded together only 285 litres per second, or 5,417,280 gallons per day; while in both these years the Soudon and the Dhuis gave almost the same quantities as in the year 1855.

In order to meet the contingency of such a dry season as 1858, Mr Belgrand's project contemplated sinking wells or adits in the chalk, and obtaining therefrom what he terms "the subterranean reservoirs of water therein contained,"—artificial supplies, which would supply any deficiency in the quantity yielded by the streams. The works comprised what are termed conduits of derivation, being subsidiary conduits for collecting the waters from the various streams, and conducting them to the commencement of the main aqueduct that conveys the waters of the combined sources to Paris. The main aqueduct commences at a level of about 105 metres above the sea. It is a little over 180 kilometres in length (about 110 English miles), and terminates at Paris in service reservoirs at Belleville, at a level of 83½ metres above the sea. The subsidiary conduits are about 80 kilometres in length, and upon these and the main aqueduct there are seventeen bridges, 6 kilometres of conduit constructed upon arches, 7 kilometres of syphon piping, and 28 kilometres of tunnel. The estimated cost of the ordinary works was about 19,000,000 francs, or £760,000, to which must be added about 2½ million francs, or £100,000, for special works, where the aqueduct had to be constructed through difficult ground, and 4½ million francs, or £180,000, for compensation to riparian owners on the streams which were selected as the sources of the supply, as well as to the owners of mills who might be injured by the abstraction of the water, and for the purchase of the lands through which the aqueduct had to be constructed; making a total estimated outlay on the works at the sources of the supply, and for the subsidiary and main aqueducts up to the distributing at Belleville, of 26,000,000 francs or £1,040,000.

The commission, to whom were referred all the projects which had been suggested, in their report, considered on the 18th of March 1859, recommended that the sum to be voted for the works should be 30,000,000 francs, or £1,200,000, thus increasing the estimate by 4,000,000 francs, or £160,000, with the view of providing ample means to cover any unforeseen works or difficulties which might be encountered during the carrying out of the project. The works have since that time been carried out substantially in accordance with the ideas and designs of Mr Belgrand, and under his direction and supervision; but they are not yet (1874) completed. The water from these sources is naturally very hard, but it is bright, fresh, and well aerated.

Although the system of pipes has superseded the use of stone channels all raised to a level in the conveyance of water, there are still cases, such as those of canals, where the water must be kept on a perfect level, and where, therefore, aqueduct bridges are still necessary in conveying it over the valleys; and of these we have long had examples in France, on the Languedoc canal. The first aqueduct bridges for canals in this country were those made by the Duke of Bridgewater, under the direction of the celebrated Brindley, and which, being quite new here, excited no small degree of astonishment. The first and largest was the aqueduct at Barton Bridge for conveying the canal across the Irwell, 39 feet above the surface of the water. It consisted of three arches, the middle one 63 feet span, and admitting under it the largest barges navigating the Irwell with sails set. It was commenced in September 1760; and in July of the following year the spectacle was first presented in this country, of vessels floating and sailing across the course of the river, while others in the river itself were passing under them. Since that period canal aqueducts have become more common; and many excellent examples are to be found both in England and Scotland. Of these are the aqueducts over the river Lune on the Lancaster canal, designed by Rennie,—a very excellent and splendid work of five arches, each 72 feet span, and rising 65 feet above the level of the river; and the Kelvin aqueduct, near Glasgow, which conveys the Forth and Clyde canal over the valley of Kelvin, consisting of four arches, each 70 feet span, and rising 70 feet above the level of the river. Plate IV. contains views of two other principal aqueducts, viz., those of Pont y Cysyllte and Chirk in Wales. Of these the Pont-y-Cysyllte aqueduct by Mr Telford is justly celebrated for its magnitude, simplicity of design, and skilful disposition of the parts, combining lightness with strength in a degree seldom attempted. This aqueduct serves to convey the waters of the Ellesmere canal across the Dee and the vale of Llangollen, which it traverses. The channel for the water is made of cast-iron, supported on cast-iron ribs or arches, and these resting on pillars of stone. The iron being much lighter than stone arches, this in one reason why the pillars have been reduced apparently to such slender dimensions. They are quite strong enough, however, as experience has proved. The whole length of the aqueduct is about 1000 feet, and consists of nineteen arches, each 45 feet span. The breadth of the pillars at the top is 8 feet, and the height of the four middle ones is 115 feet to the springing. The pillars have a slight taper, the breadth of the middle ones at the base being 15 feet. The height from the surface of the water in the Dee to that in the canal is 126 feet 8 inches. The channel for the water consists of cast-iron plates, cast with flanches, and these screwed together with bolts; they are represented in the drawing, between the arched ribs and the railing. The lines there show the joinings of the different plates. In order to preserve as much water-way as possible, the channel is made the full width of the canal and towing-path, and the latter projected over one side, and supported inside by posts resting on the bottom of the canal. The aqueduct of Chirk was designed by the same able engineer, and serves also to convey across a valley the waters of the same canal. This aqueduct was the first in which iron was employed. Hitherto the channel for the waters had been constructed of stone, or partly of stone and partly of clay puddle, which it was generally found very difficult to keep water-tight for a length of time. It was determined, therefore, by Mr Telford, to try the effect of cast-iron, and to lay it at first only on the bottom. The plates were accordingly laid directly over the sprandril walls, which they served to bind together, and united by flanches and screws. The sides of the channel were built with stone facings and brick hearting laid in water-lime mortar. This plan succeeded completely, and the quantity of masonry in the aqueduct was thereby greatly reduced. The aqueduct itself is 600 feet long, and 65 feet high above the river, consisting of ten arches, each 42 feet span. The piers are 10 feet thick.

An aqueduct near Edinburgh, conveying the waters of the Edinburgh and Glasgow Union Canal across the valley of the Water of Leith at Slateford, is an elegant structure, similar in plan to that of Chirk, only that the water-channel is composed entirely of cast-iron, which is moreover built in with masonry. It is about 500 feet in length, and consists of eight arches, each 45 feet span; and the height of the canal is about 70 feet above the level of the river. On this canal another aqueduct of the very same construction occurs in crossing the valley of the Almond, and having several more arches. There are, in different parts of the country, various other aqueducts, but, excepting the formation of the water-way, these structures differ in no respect from bridges, particularly those undertaken not so much with the view of crossing rivers as of raising the level of the road entirely out of the valley,—an object now become of great importance, from the improvements in modern modes of conveyance. For the principles and mode of construction of these works, as well as of the aqueduct bridges so far as the arch is concerned, see articles ARCH and BRIDGE.

(A. S. M.—J. F. B.)

AQUILA, a town of Italy, capital of the province of Abruzzo Ulteriore II., beautifully situated on the Aterno, about 56 miles from Rome. It is a well-built place, containing a citadel, which dates from 1534, a cathedral (*S. Bernardino du Siena*), as well as numerous other churches and religious establishments, a theatre, a fine town-hall, and a number of ancient mansions, such as the *Palazzo Torres*, with its picture-gallery, and the *Palazzo del Governo*, the residence of Margaret of Austria. Its chief manufactures are paper, linen, and wax; and it has a large trade in saffron, the principal product of the surrounding district. Aquila was founded about the year 1240, by the emperor Frederick II. who peopled it with the inhabitants of the ancient *Amiternum*, the birthplace of Sallust, the ruins of which are still to be seen about 3 miles from the town. It soon became a very flourishing city; but war, pestilence, and especially earthquakes (1703, 1706), have done much to reduce its importance. Population, 16,607.

AQUILA (Ἀκύλας), a native of Pontus, who flourished about 130 A.D., celebrated for his translation of the Hebrew Scriptures into Greek. His history is involved in much obscurity; but, according to Epiphanius (*De Pond. et Mens.*, c. 15), he was a kinsman of the Emperor Hadrian, who employed him in rebuilding Jerusalem (Ælia Capitolina), and was converted to Christianity, but on being reproved for practising the pagan astrology, apostatised to Judaism. This account, however, is more than doubtful. Aquila's version of the Scriptures was exceedingly close and accurate, and is said to have been used in place of the Septuagint in the synagogues. Though the Christians generally disliked it, alleging without due grounds that it rendered the Messianic passages incorrectly, Jerome and Origen speak in its praise. The few fragments that remain are published in the *Hexapla* of Origen, and in Dathe's *Opuscula*, Lips. 1746.

AQUILA, Caspar, the Latin name of Kaspar Adler, a celebrated German theologian who espoused the cause of the Reformation. He was born at Augsburg in 1488; and after studying there as well as at Berne and Leipsic, and for several years in Italy, he was appointed pastor of Jenga, a village near Augsburg. Here he embraced the doctrines of Luther; but his boldness and zeal in the cause of the reformed faith led the bishop of Augsburg to order his arrest. Aquila passed the winter of 1519–1520 in the prison of Dillingen, and was only liberated through the influence of Isabella of Denmark, sister of the emperor Charles V. From Dillingen he went to Wittenberg, where he became personally acquainted with Luther; and thence he went as tutor to the family of Franz von Sickingen, in the castle of Ebernburg. After a short stay at Eisenach, Aquila was appointed professor of Hebrew at Wittenberg, where he rendered valuable assistance to his colleague Luther in his translation of the Old Testament. In 1527 he became pastor, and the following year Protestant bishop at Saalfeld; but his vehement opposition to the *Interim* of Charles V. in 1548, obliged him to flee from the place, and accept the offer from the countess of Schwarzburg of a temporary asylum in her castle of Rudolfstadt. He was appointed to the deanery of Schmalkalden in 1550, and restored two years after to his office at Saalfeld, where, without further molestation, he continued to discharge his duties till his death, 12th November 1560. The writings he has left are chiefly sermons and controversial works.

AQUILA, Serafino dell', a famous Italian poet and improvisatore, was born in 1466 at the town of Aquila, from which he took his name, and died in the year 1500. He spent several years at the courts of Cardinal Sforza and Ferdinand, duke of Calabria; but his principal patrons were the Borgias at Rome, from whom he received many favours. Aquila seems to have aimed at an imitation of Dante and Petrarch; and his poems, which were extravagantly praised during the author's lifetime, are occasionally of considerable merit. His reputation was in great measure due to his remarkable skill as an improvisatore and musician. His works were printed at Venice in 1502, and there have been several subsequent editions.

AQUILEIA, an ancient city, at the head of the Adriatic, founded or at least colonised by the Romans about 181 B.C., which, on account of its commanding the north-eastern entrance into Italy, soon rose into importance as a commercial centre and as a military post. Connected by the Æmilian way with the capital and the south, it was also the starting-place of the roads to Rhætia, Pannonia, Istria, and Dalmatia. The surrounding territory was highly fertile, and yielded abundance of wine; while gold was found in considerable quantities in the neighbourhood. Aquileia was chosen by Julius Cæsar as headquarters for his forces in Cisalpine Gaul, and was frequently the *point d'appui* of imperial campaigns. It was strongly fortified by Marcus Aurelius in 160, and was able in 238 to frustrate the long-continued siege of Maximin. About this time it was one of the most important and flourishing cities of all Italy. It was recognised as the capital of Venetia, and allowed to have the altogether exceptional privilege of a mint. In 361 the city was captured by Jovinus; and in 381 it was the seat of a council, in which St Ambrose obtained the excommunication of Palladius. In 388 it surrendered to Theodosius the Great his antagonist Maximus; and in 425 Joannes, the rebel against Theodosius II., was led in derision through its streets on an ass, and then beheaded in its circus. In 452 it was taken and destroyed by Attila, and though restored by Narses in 552, it never recovered its former prosperity. At the council of 556 its bishop—whose predecessors can be traced back to the 3d century—separated from the Church of Rome, and took the title of Patriarch, which was recognised by Pope Sergius I. at the council of 698, when the schism was brought to a close. By 924, under the rule of its patriarchs, it was strong enough to extend its authority over Friuli; and it continued to enjoy considerable prosperity, until it was at length deprived of most of its possessions by Venice in 1420. Its patriarchs had indeed already removed their residence to the castle of Udine, and the Venetian conquest only hastened the decay that had previously begun. The patriarchate was abolished in 1758, and the territory divided into the two bishoprics of Udine and Gorizia. It is now a small fishing village of 1956 inhabitants, containing a number of interesting remains of its ancient splendour, and often rewarding the researches of the antiquary with relics of value. (Gian. Dom. Bertoli, *Le Antichite di Aquileja, profane e sacre*, Ven. 1739.)

AQUILLIUS, Manius, was Roman consul in 101 B.C., and successfully reduced a revolt of slaves in Sicily. He was afterwards accused of receiving money illegally, but was acquitted by an artifice of his counsel, who exhibited to the people the scars of wounds received by his client in war. In 88 B.C. he acted as legate against Mithridates, by whom he was defeated and taken prisoner. Mithridates treated him with great cruelty, and finally put him to death by pouring molten gold down his throat.

AQUINAS, Thomas [Thomas of Aquin or Aquino], was of noble descent, and nearly allied to several of the royal houses of Europe. He was born in 1225 or 1227, at Rocca Sicca, the castle of his father Landulf, count of Aquino, in the territories of Naples. Having received his elementary education at the monastery of Monte Cassino, he studied for six years at the University of Naples, leaving it in his sixteenth year. While there he in all probability came under the influence of the Dominicans, who were then the rising order in the church, and were doing their utmost to enlist within their ranks the ablest young scholars of the age, for in spite of the opposition of his family, and especially of his mother (an opposition which was overcome only by the intervention of Pope Innocent IV.), he assumed the habit of St Dominic in his seventeenth year.

His superiors, seeing his great aptitude for theological study sent him to the Dominican School in Cologne, where Albertus Magnus, the most famous thinker of his age, lectured on philosophy and theology. In 1245 Albertus was called to Paris, and there Aquinas followed him, and remained with him for three years, at the end of which he graduated as bachelor of theology. In 1248 he returned to Cologne with Albertus, and was appointed second lecturer and *magister studentium*. This year may be taken as the beginning of his literary activity and public life. Ere he left Paris he had thrown himself with ardour into the controversy raging between the University and the Begging Friars respecting the liberty of teaching, resisting both by speeches and pamphlets the authorities of the University; and when the dispute was referred to the Pope, the youthful Aquinas was chosen to defend his order, which he did with such success as to overcome the arguments of the celebrated William of St Amour, the champion of the University, and one of the most celebrated men of the day. In the year 1257, along with his friend Bonaventura, he was created doctor of theology, and began to give courses of lectures upon this science in Paris, and also in Rome and other towns in Italy. From this time onwards his life was one of incessant toil, and we marvel at the amount of literary work he was able to do, when we remember that during his short public life he was continually engaged in the active service of his order, was frequently travelling upon long and tedious journeys, and was constantly consulted on affairs of state by the reigning pontiff.

In 1263 we find him at the chapter of the Dominican order held in London. In 1268 he was lecturing now in Rome and now in Bologna, all the while engaged in the public business of the church. In 1271 he was again in Paris, lecturing to the students, managing the affairs of the church, and consulted by the king, Louis VIII., his kinsman, on affairs of state. In 1272 the commands of the chief of his order and the request of King Charles brought him back to the professor's chair at Naples. All this time he was preaching every day, writing homilies, disputations, lectures, and finding time to work hard at his great work the *Summa Theologiæ*. Such rewards as the church could bestow had been offered to him. He refused the archbishopric of Naples and the abbacy of Monte Cassino. In January 1274 he was summoned by Pope Gregory X. to attend the council convened at Lyons, to investigate and if possible settle the differences between the Greek and Latin churches. Though suffering from illness, he at once set out on the journey; finding his strength failing on the way, he was carried to the Cistercian monastery of Fossa Nuova, in the diocese of Terracina, where, after a lingering illness of seven weeks, he died on the 7th of March 1274. After his death the highest honours which the church could bestow were awarded to the memory of Thomas. He was canonised in 1323 by Pope John XXII., and in 1567 Pius V. ranked the festival of St Thomas with those of the four great Latin fathers, Ambrose, Augustine, Jerome, and Gregory. Still higher is the honour implied in the fact, that no theologian save Augustine has had the same influence on the theological thought and language of the Western Church, and that no man has better fulfilled the ideal of the monkish life than Thomas of Aquin.

The writings of Thomas are of very great importance for philosophy as well as for theology, for he is the spirit of scholasticism incarnate, and has done more than any other writer save Augustine to fashion the theological language of the Western Church. The mediæval spirit, in all its various manifestations, aimed at universal empire by way of external and visible rule. Its idea of the State was the Holy Roman Empire actually embracing and dominating over all the countries in Europe; its idea of the Church, that visible and tangible catholicity which existed before the great Reformation; and in the department of knowledge it showed its characteristic quality in its desire to embrace in one system, under one science, the whole of human thought. It so happened that, in the break between the old world and the new, the sole institution which survived was the church, and the only science which was preserved was philosophy. Hence, when scholasticism arose, the science which it found ready to its hand was theology, and its task became that of bringing all departments of knowledge under the dominion of this one sovereign science. All through the period of scholasticism, from its beginning under Scotus Erigena down to its decline under Gabriel Biel, this aim of establishing an empire of science was kept in view, and no fresh advance in knowledge in any fresh field of investigation was ever held to be made or taken possession of until its results had been brought under the influence of the master science, and made to occupy their proper and subordinate place. Aquinas occupies the central point in the history of scholasticism, because he, more than any other, was trained by nature and education to do the most that could be done to realise the scholastic ideal, and present a condensed summary of all known science, under the title of *Summa Theologiæ*.

The principles on which the system of Aquinas rested were these. He held that there were two sources of knowledge—the mysteries of Christian faith and the truths of human reason. The distinction between these two was made emphatic by Aquinas, who is at pains, especially in his treatise *Contra Gentiles*, to make it plain that each is a distinct fountain of knowledge, but that revelation is the more important of the two. It is important to mark what Aquinas means by revelation and by reason. Revelation is a source of knowledge, rather than the manifestation in the world of a divine life, and its chief characteristic is that it presents men with mysteries, which are to be believed even when they cannot be understood. Revelation is not Scripture alone, for Scripture taken by itself does not correspond exactly with his description; nor is it church tradition alone, for church tradition must so far rest on Scripture. Revelation is a divine source of knowledge, of which Scripture and church tradition are the channels; and he who would rightly understand theology must familiarise himself with Scripture, the teachings of the fathers, and the decisions of councils, in such a way as to be able to make part of himself, as it were, those channels along which this divine knowledge flowed. Aquinas's conception of reason is in some way parallel with his conception of revelation. Reason is in his idea not the individual reason, but fountain of natural truth, whose chief channels are the various systems of heathen philosophy, and more especially the thoughts of Plato and the methods of Aristotle. Reason and revelation are both of them separate sources of knowledge, which have their appropriate channels; and man can put himself in possession of each, because he can bring himself into relation to the church on the one hand, and the system of philosophy, or more strictly Aristotle, on the other. The conception will be made clearer when it is remembered that Aquinas, taught by the mysterious author of the writings of the Pseudo-Dionysius, who so marvellously influenced mediæval writers, sometimes spoke of a natural revelation, or of reason as a source of truths in themselves mysterious, and was always accustomed to say that reason as well as revelation contained two kinds of knowledge. The first kind lay quite beyond the power of man to receive it, the second was within man's reach. In reason, as in revelation, man can only attain to the lower kind of knowledge; there is a higher kind which we may not hope to reach.

But while reason and revelation are two distinct sources of truths, coming to men by two distinct means of conveyance, the supernatural and the natural means for the delivery of truth, and apprehended by two distinct faculties, reason and faith, the truths which each reveal are not in themselves contradictory; for in the last resort they rest on *one* absolute truth—they come from the one source of knowledge, God, the Absolute One. Hence arises the compatibility of philosophy and theology which was the fundamental axiom of scholasticism, and the possibility of a Summa Theologiæ, which is a Summa Philosophiæ as well. All the many writings of Thomas are preparatory to his great work the *Summa Theologiæ*, and show us the progress of his mind training for this his life work. In the *Summa Catholicæ Fidei contra Gentiles* he shows how a Christian theology is the sum and crown of all science. This work is in its design apologetic, and is meant to bring within the range of Christian thought all that is of value in Mahometan science. He carefully establishes the necessity of revelation as a source of knowledge, not merely because it aids us in comprehending in a somewhat better way the truths already furnished by reason, as some of the Arabian philosophers and Maimonides had acknowledged, but because it is the absolute source of our knowledge of the mysteries of the Christian faith; and then he lays down the relations to be observed between reason and revelation, between philosophy and theology. This work, *Contra Gentiles*, may be taken as an elaborate exposition of the method of Aquinas. That method however, implied a careful study and comprehension of the results which accrued to man from reason and revelation, and a thorough grasp of all that had been done by man in relation to those two sources of human knowledge; and so, in his preliminary writings, Thomas proceeds to master the two provinces. The results of revelation he found in the Holy Scriptures and in the writings of the fathers and the great theologians of the church; and his method was to proceed backwards. He began with Peter of Lombardy (who had reduced to theological order, in his famous book on the *Sentences*, the various authoritative statements of the church upon doctrine) in his *In Quatuor Sententiarum P. Lombardi libros.* Then came his deliverances upon undecided points in theology, in his *XII. Quodlibeta Disputata*, and his *Quæstiones Disputatæ*. His *Catena Aurea* next appeared, which, under the form of a commentary on the Gospels, was really an exhaustive summary of the theological teaching of the greatest of the church fathers. This side of his preparation was finished by a close study of Scripture, the results of which are contained in his commentaries, *In omnes Epistolas Divi Apostoli Expositio*, his *Super Isaiam et Jeremiam*, and his *In Psalmos.* Turning now to the other side, we have evidence, not only from tradition but from his writings, that he was acquainted with Plato and the mystical Platonists; but he had the sagacity to perceive that Aristotle was *the* great representative of philosophy, and that his writings contained the best results and method which the natural reason had as yet attained to. Accordingly Aquinas prepared himself on this side by commentaries on Aristotle's *De Interpretatione*, on his *Posterior Analytics*, on the *Metaphysics*, the *Physics*, the *De Anima*, and on the other psychological and physical writings of the great master, each commentary having for its aim to lay hold of the material and grasp the method contained and employed in each treatise. Fortified by this exhaustive preparation, Aquinas began his *Summa Theologiæ*, which was to be for human thought what the Holy Roman Empire was for the bodies, and the Holy Catholic Church was for the souls of men. It was to be a visible empire of thought, exhaustive, all-embracing, and sovereign. The *Summa Theologiæ* was meant to be the sum of all known learning, arranged according to the best method, and subordinate to the dictates of the church; that was the intention of the book; practically it came to be the theological dicta of the church, explained according to the philosophy of Aristotle and his Arabian commentators. The *Summa* is divided into three great parts, which shortly may be said to treat of God, Man, and the God-Man. The first and the second parts are wholly the work of Aquinas, but of the third part only the first 90 quæstiones are his; the rest of it was finished in accordance with his designs. The first book, after a short introduction upon the nature of theology as understood by Aquinas, proceeds in 119 questions to discuss the nature, attributes, and relations of God; and this is not done as in a modern work on theology, but the questions raised in the physics of Aristotle find a place alongside of the statements of Scripture, while all subjects in any way related to the central theme are brought into the discourse. The second part is divided into two, which are quoted as *Prima Secundæ* and *Secunda Secundæ*. This second part has often been described as ethic, but this is scarcely true. The subject is man, treated as Aristotle does, according to his τέλος, and so Aquinas discusses all the ethical, psychological, and theological questions which arise; but any theological discussion upon man must be mainly ethical, and so a great proportion of the first part, and almost the whole of the second, has to do with ethical questions. In his ethical discussion Aquinas distinguishes theological from natural virtues and vices: the theological virtues are faith, hope, and charity; the natural, justice, prudence, and the like. The theological virtues are founded on faith, in opposition to the natural, which are founded on reason; and as faith with Aquinas is always belief in a proposition, not trust in a personal Saviour, conformably with his idea that revelation is a new knowledge rather than a new life, the relation of unbelief to virtue is very strictly and narrowly laid down and enforced. The third part of the *Summa* is also divided into two parts, but by accident rather than by design. Aquinas died ere he had finished his great work, and what has been added to complete the scheme is appended as a *Supplementum Tertiæ Partis.* In this third part Aquinas discusses the person, office, and work of Christ, and had begun to discuss the sacraments, when death put an end to his labours.

The best edition of the works of Aquinas is the Venice one of 1787, in twenty-eight 4to vols. It contains the useful dissertations of Bernhard de Rubeis. The Abbé Migne has published a very useful edition of the *Summa Theologiæ*, in four 8vo vols., as an appendix to his *Patrologiæ Cursus Completus.* See *Acta Sanct.*, vii. Martii; Touron, *La vie de St Thomas d'Aquin avec un exposé de sa doctrine et de ses ouvrages*, Paris, 1737; Dr Karl Werner, *Der Heilige Thomas von Aquino*, 1858; and Dr R. B. Vaughan, *St Thomas of Aquin, his Life and Labours*, London, 1872. For the philosophy of Aquinas, see Albert Stöckl, *Geschichte der Philosophie des Mittelalters*, ii.; Hauréau, *De la Philosophie Scolastique*, tome ii.; and Ueberweg's *History of Philosophy*, vol. i. (T. M. L.)

AQUITANIA. This was, in the time of Julius Cæsar, the name given to that part of Gallia which lay between the Garumna and the Pyrenees, and was inhabited by a race distinct from the Celtæ. According to Bial and Belloguet, Aquitani is probably a form of Auscetani, a Hispanic lengthening of Ausces (Ausks, Wasks, Basques), and Aquitania would thus be radically identical with Gascony (Wasconia), a word of much later introduction into geographical nomenclature. Though the greater proportion of the Aquitanian tribes made submission to Cæsar, it was not till 28 B.C. that the region was fairly brought under the Roman yoke by M. Valerius Messala. In keeping with the imperial policy of denationalisation, the term Aquitania was extended, in the division of Gallia under Augustus, to the whole stretch of country south and east of the continuous course of the Loire and the Allier, and thus ceased to be of ethnographical import. In the 3d century after Christ this extended Aquitania was divided into three parts. *Aquitania Prima* consisted of the eastern portion of the district between the Loire and the Garonne; *Aquitania Secunda*, of the western part of the same district; and *Aquitania Tertia* or *Novempopulania*, of the region between the Pyrenees and the Garonne, or the original Aquitania. Like the rest of Gaul, Aquitania absorbed a large measure of Roman civilisation which continued to distinguish the district down to a late period. In the 5th century the Visigoths established themselves in Aquitania Secunda, and in some cantons of Narbonensis Prima and Novempopulania. As their power also included Spain, it was usual to speak of their Gallic possessions as Spain likewise. The Merovingian kings extended their authority nominally to the Pyrenees; but as Guizot has remarked (*Essais*, No. ii.) "the conquest of Aquitania by Clovis left it almost as alien to the people and king of the Franks as it had formerly been." For a time indeed, about 630, the Aquitanians rallied round Haribert (Charibert), the brother of Dagobert, in hope of national independence, even under a Frankish ruler; but the usual story that their ducal family was descended from him rests on a forgery (*v.* Henri Martin, *Hist. de France*, vol. ii. p. 137). About the end of the 7th century, an adventurer named Eudes or Eudon had made himself master of the region. Attacked by the Saracens, he inflicted on them a crushing defeat but, on their reappearance, was obliged to call in the aid of Charles Martel, who, as the price of his assistance, claimed the homage of his ally. He was succeeded by his son Hunald, who, after carrying on a war against the aggressions of Pepin the Short, retired to a convent, and left the conflict and the kingdom to Guaifer (Waifer). For nine years he strenuously maintained the hopeless strife, till his assassination in 768. With him perished for a time the national independence, but not the national individuality, of the Aquitanians. The kingdom of Aquitania was bestowed by Charlemagne on the infant Louis in 781; and from him it was transmitted to his son Pepin, on whose death the Aquitanians loyally chose Pepin the younger, but were opposed by Louis, who gave the crown to Charles the Bald. Hence ensued a long period of confusion and conflict, which resulted in the comparative success of Charles, who granted the Aquitanians a nominal separation from Neustria, and gave them his son Charles, eight years old, to be their nominal king (855)—nominal, not only because he was a child, but because his kingdom was in a state of anarchy through domestic faction and foreign invasion. On his death (866), Louis the Stammerer succeeded to the titular sovereignty. About 886 Guilhem (William) the Pious, count of Auvergne, the founder of the abbey of Cluny, obtained the title of Duke of Aquitania, and transmitted it (918) to Guilhem II. He was followed in succession by Raimond Pons, count of Toulouse (d. 950), Guilhem Tête d'Etoupes, count of Poitiers (d. 963), Guilhem Fier-à-Bras, whose sister was married by Hugh Capet (970), and Guilhem the Great (977–1030), who had hard work to maintain his ground, but at last changed his title into an effective lordship. His duchy almost reached the limits of the I. and II. Aquitania of the Romans, but did not extend south of the Garonne, that district having been ever since the 6th century in the possession of the Gascons. Guilhem refused the empire offered him by the Italians, and died at Maillezais. Meanwhile civilisation and refinement were gradually increasing. The names of Guilhem VI. (d. 1038), Guilhem VII., who joined Gascony and Bordeaux to his duchy, and married his daughter to Henry the Black, and Guilhem VIII. bring us down to Guilhem IX., who succeeded in 1086, and made himself famous as crusader and troubadour. Guilhem X. (d. 1137) married his daughter to Louis VII. of France, and Aquitania went as her dowry. On her divorce from Louis and marriage with Henry II. of England (1152), her possession passed to her new husband, and from that time continued to follow the fortunes of the English territories in France. The name Guienne, the modern corruption of Aquitania, seems to have come into use about the 10th century. An interesting literary relic of the struggle between the Franks and the Gallo-Roman inhabitants of Aquitania exists under the title of *Walther d'Aquitaine* (see Fauriel's *Poésie Provençale*), but the historical value of this work has been questioned.

ARABESQUE, a term to which a meaning is now commonly given that is historically incorrect. We apply it to the grotesque decoration derived from Roman remains of the early time of the empire, not to any style derived from Arabian or Moorish work; the term is therefore a misnomer. Arabesque and Moresque are really distinct; the latter is from the Arabian style of ornament, developed by the Byzantine Greeks for their new masters, after the conquests of the followers of Mahomet; and the former is a term pretty well restricted to varieties of cinquecento decoration, which have nothing in common with any Arabian examples in their details, but are a development derived from Greek and Roman grotesque designs, such as we find them in the remains of ancient palaces at Rome, and in ancient houses at Pompeii. These were reproduced by Raphael and his pupils in the decoration of some of the corridors of the Loggie of the Vatican at Rome: grotesque is thus a better name for these decorations than Arabesque.

This technical Arabesque, therefore, is much more ancient than any Arabian or Moorish decoration, and has really nothing in common with it except the mere symmetrical principles of its arrangement. Pliny and Vitruvius give us no name for the extravagant decorative wall-painting in vogue in their time, to which the early Italian revivers of it seem to have given the designation of grotesque, because it was first discovered in the arched or underground chambers (*grotte*) of Roman ruins—as in the golden house of Nero, or the baths of Titus. What really took place in the Italian revival was in some measure a supplanting of the Arabesque for the classical grotesque, still retaining the original Arabian designation, while the genuine Arabian art, the Saracenic, was distinguished as Moresque or Moorish. So it is now the original Arabesque that is called by its specific names of Saracenic, Moorish, and Alhambresque, while the term Arabesque is applied exclusively to the style developed from the debased classical grotesque of the Roman empire.

There is still much of the genuine Saracenic element in Renaissance Arabesques, especially in that selected for book-borders and for silver-work, the details of which consist largely of the conventional Saracenic foliations. But the Arabesque developed in the Italian cinquecento work repudiated all the original Arabian elements and devices, and limited itself to the manipulating of the classical elements, of which the most prominent feature is ever the floriated or foliated scroll; and it is in this cinquecento decoration, whether in sculpture or in painting, that *Arabesque* has been perfected.

We will first briefly describe the Saracenic, as the elder sister of the two styles, which was ingeniously developed by the Byzantine Greek artists for their Arabian masters in the early times of Mahometan conquest. Every natural object was proscribed; the artists were, therefore, reduced to making symmetrical designs from forms which should have no positive meaning; yet the Byzantine Greeks, who were Christians, managed to work even their own ecclesiastical symbols, in a disguised manner, into their tracery and diapers; as the lily, for instance. The cross was not so introduced; this, of course, was inadmissible; but neither was the crescent ever introduced into any of this early work in Damascus or Cairo. The crescent was itself not a Mahometan device till after the conquest of Constantinople in 1453 A.D. The crescent, as the new moon, was the symbol of Byzantium; and it was only after that capital of the Eastern empire fell into the hands of the Turks that this symbol was adopted by them. The crescent and the cross became antagonist standards, therefore, first in the 15th century. And the crescent is not an element of original Moorish decoration.

The Alhambra diapers and original Majolica (Majorca) ware afford admirable specimens of genuine Saracenic or Moorish decoration. A conventional floriage is common in these diapers; tracery also is a great feature in this work, in geometrical combinations, whether rectilinear or curvilinear; and the designs are rich in colour: idolatry was in the reproduction of natural forms, not in the fanciful combination of natural colours. These curves and angles, therefore, or interlacings, chiefly in stucco, constitute the prominent elements of an Arabian ornamental design, combining also Arabic inscriptions; composed of a mass of foliation or floral forms conventionally disguised, as the exclusion of all natural images was the fundamental principle of the style in its purity. The Alhambra displays almost endless specimens of this peculiar work, all in relief, highly coloured, and profusely enriched with gold. The mosque of Touloun, in Cairo, 876 A.D., the known work of a Greek, affords the completest example of this art in its early time; and Sicily contains many remains of this same exquisite Saracenic decoration.

Such is the genuine Arabesque of the Arabs, but a very different style of design is now implied by the term—the Arabesque of the cinquecento, a purely classical ornamentation. This owes its origin to the excavation and recovery of ancient monuments, and was developed chiefly by the sculptors of the north, and the painters of Central Italy; by the Lombardi of Venice, by Agostino Busti of Milan, by Bramanti of Urbino, by Raphael, by Giulio Romano, and others of nearly equal merit.

Very beautiful examples in sculpture of this cinquecento Arabesque are found in the churches of Venice, Verona, and Brescia; while in painting, the most complete specimens are those of the Vatican Loggie, and the Villa Madama at Rome and the ducal palaces at Mantua. The Vatican Arabesques, chiefly executed for Raphael by Giulio Romano, Gian Francesco Penui, and Giovanni da Udine, though beautiful as works of painting, are often very extravagant in their composition, ludicrous, and sometimes æsthetically offensive; as are also many of the decorations of Pompeii. The main features of these designs are balanced scrolls in panels; or standards variously composed, but symmetrically scrolled on either side, and on the tendrils of these scrolls are suspended or placed birds and animals, human figures and chimeras, of any or all kinds, or indeed any objects that may take the fancy of the artist. But he is limited by the laws of æsthetics; his designs must be symmetrical or they will want harmony, and they must not offend against mechanical possibility or the principle of gravitation, or they will be ridiculous: nothing that outrages æsthetic sensibility can ever be beautiful. The most perfect specimens of cinquecento Arabesque are certainly found in sculpture. As specimens of exquisite work may be mentioned the Martinengo tomb, in the church of the Padri Riformati at Brescia, and the façade of the church of Santa Maria dei Miracoli there, by the Lombardi; and many of the carvings of the Château de Gaillon, France—all of which fairly illustrate the beauties and capabilities of the style.

This kind of decoration need not, however, be limited to architectural panels and pilasters; it is applicable for large surface decoration, and for manufactures, whether in wood or metal, or textile. It affords as much room also for the display of colour as of form: some of the surface decorations of Gærtner, in Munich, are splendid examples of delicacy of colour, showing how much may be effected by harmonious combinations in scroll-work of the most delicate gradations and tints. Good specimens of Arabesque, in manufactures, in casts, and in copies in colour, may now be seen in the South Kensington Museum. For fuller details of style, see Wornum, *Analysis of Ornament*, &c., 4to edition, 1874, illustrated. (R. N. W.)

ARABGIR, or ARABKIR, a town of Turkey in Asia, in the vilayet of Sivas, situated in a deep ravine near a small tributary of the Euphrates, 150 miles S.S.W. of Trebizond. The inhabitants are enterprising and prosperous, many of them leaving their native city to push their fortunes elsewhere, while of those that remain the greater part are employed in the manufacture of silk and cotton goods, or in the production of fruit. The present town was built at a comparatively recent date, but about 2 miles to the north-east is the old town, now called Eski Shehr, containing the ruins of a castle and of other buildings. Arabgir contains about 6000 houses. About three-fourths of the population are Turks, and the remainder Armenians.

ARABIA

Sources of information. OUR information in regard to the physical character of Arabia must be chiefly derived from the accounts given by European travellers; amongst whom Niebuhr, Burckhardt, Wallin, Welsted, and Palgrave have been on this occasion chiefly consulted; and to their works the reader must necessarily be referred for a variety of details impossible to compress into a summary like the present.

Extent of Arabia. Arabia is a peninsula stretching from north-west to south-east, between 30° and 12° 45′ N. lat., and between 32° 30′ and 60° E. long. Its form is that of an irregular parallelogram, almost a triangle indeed, bounded on the W., S., and E. by the Red Sea, the Indian Ocean, and the Persian Gulf respectively; on the N., where runs its narrowest limit, it joins on to the mainland of Syria. Its correct boundary in this direction would be assigned by a line drawn transversely, west and east, from Suez to the head of the Persian Gulf. But some writers, Burckhardt included, add to this extent all the Syrian desert behind Palestine, and the valleys of the Jordan and Orontes up to the village of Anah, on the Euphrates, 34° N. lat.; and then down again by the right bank of that river to where, joined by the Tigris, it takes the name of Shatt-el-Arab, and

so to the Persian Gulf again. Roman geographers make Arabia the further present of Mesopotamia; and Abul-Feda, an Aleppine of the 13th century, would even bring its denomination so far north as to include Aleppo. We will, however, accept the first-mentioned as the most correct line of demarcation. According to this, the extreme length of the Arabian peninsula, from the head of the gulf of Akabah to the straits of Bab-el-Mandeb would be about 1300 miles; its greatest breadth, in 23° N. lat., from the Red Sea coast, west, to Ras-el-Hadd, east, 1500 miles; and its apex, where it joins on to the continent of Asia, rather under 900 miles.

Western coast. The western coast is washed by the Red Sea. It exhibits a range of low mountains, seldom exceeding 2000 feet in height, abrupt in outline, and generally barren; between them and the sea is a narrow and sandy strip fringed along the margin with coral reefs. Its aspect from the sea is almost everywhere desolate in the extreme. Nor does the entire coast-line present a single harbour, properly speaking, where anything larger than an ordinary schooner could find entry; only roadsteads, the approaches to which are often rendered difficult by shoals and reefs. The Arab side of the Red Sea, especially in the southern half, is thickly studded with small islands, some of which—Kotembel and Pebel Tar in particular—are of volcanic origin. A few fishermen inhabit some of them; but none—the island of Perim, near the entrance of the Bab-el-Mandeb straits, lately occupied by a British garrison, alone excepted—are of any importance.

South-eastern coast. The south-eastern coast, extending from Bab-el-Mandeb up to Ras-el-Hadd, is not less dreary than that of Hejaz in appearance, and, like it, presents a low and barren mountain range, diversified only by jagged rocks amid tracts of sand; but it possesses several good harbours—that of Aden in particular, now a British coaling station, about 100 miles east of Bab-el-Mandeb; that of Dafar, further up; and that of Keshum; though the two last, owing to the want of traffic with the interior, now serve as mere ports of refuge. Along this shore lie several islands, the largest being that of Mozeyrah, near Ras-el-Hadd, but they are only the haunts of a few half-savage fishermen, or are wholly desert.

Persian Gulf coast. The third coast, reaching from Ras-el-Hadd to the top of the Persian Gulf, is of a more cheerful character. Its easterly half, from Ras-el-Hadd to Cape Musandam, is in general fertile, well-cultivated, and backed up by the lofty forest-sprinkled chain of Jebel Akhdar, or the "Green Mountain." Here is situated the excellent harbour of Mascat, one capable of admitting the largest vessels to an almost land-locked shelter; besides other smaller but secure ports. Passing Cape Musandam to the west and north, the coast, though low and sandy in some places, is in others palm-fringed and cultivated; and the neighbourhood of the shallow harbour of Kateef, opposite Bahreyn, is especially fertile. Near the head of the gulf is the harbour, a very good one, of Koweyt, called also Grane. It furnishes the best ships and sailors of these seas. Many islands stud the Gulf Ormuz, famous in Persian and, later, in Portuguese history. Near the narrow entrance, by Cape Musandam, not far off, extends Ishm, a large and fertile island; higher up lie side by side the sister islands of Bahreyn, Menaneh, and Moharrik, where commence, and continue eastward all along the neighbouring coast of Katar, the most productive pearl fisheries in the world. But countless shoals and reefs render the navigation of the Persian Gulf scarcely less dangerous than that of the Red Sea; storms, too, often arise suddenly on its waters, and shipwrecks are of frequent occurrence.

General features. Arabia, taking it as a whole, cannot be called a fertile country. Its general features are those of an elevated table-land, backed up by low mountains to the west, and gradually rising in the direction of the east and south, where we find it bordered by a second and loftier mountain range. The mountains, if we except Jebel Akhdar in Oman, are almost wholly barren on their sea side; but are occasionally fertile enough on their inner ranges, especially in Yemen and the southerly districts. Their outlines are rugged and precipitous to a degree that, joined with the refraction of an over-heated atmosphere, gives them from a distance an appearance of being of a much greater height than they really are. Behind them lies an uninterrupted ring of sterile desert, broadest on the south and east, where it expands into a huge waste of burning sand; narrower towards the west and north, where it is more rocky in its character. Within this belt rises a series of table-lands, undulating in long slopes, and intersected with deep valleys; the former rich in pasturage, the latter in field and garden produce. This central plateau constitutes about one-third of the total superficies of the peninsula; the desert ring another third: the coast ranges make up the rest.

Divisions of Arabia.

In describing Arabia, the ancients, whose knowledge on the subject was slight, were accustomed to lay down an imaginary tripartite division, founded on the natural qualities of those districts with which they were more or less acquainted; and accordingly portioned off Arabia into Petræa, Deserta, and Felix, or the Stony, the Desert, and the Happy; without, however, assigning any very distinct boundaries to these regions. More modern geographers, Eastern and European, have, with better but still inadequate information, either multiplied or confounded the main divisions of the peninsula. Much indeed of its surface is even now unknown to us, except by the uncertain hearsay of Arab narrators. However, the ground-plan laid down by Niebuhr, the most accurate and painstaking of travellers, is substantially correct, and has been so often confirmed, never invalidated, by later discoveries, that we may safely follow its indications.

Sinaitic peninsula.

Beginning from the north-west, the first district we meet with is that of the Sinaitic peninsula, a small triangle having its apex on the Red Sea, its base on Palestine, and its sides formed by the Gulf of Suez on the west, and that of Akabah on the east. It is a mere collection of naked rocks and craggy precipices, intersected by long narrow defiles and sandy valleys, in which tamarisk bushes, dwarf acacias, thorny shrubs, and some kinds of euphorbia, are almost the only vegetation; in a few favoured spots a cluster of wild date-palms may occasionally be met with; and the scanty soil after the spring rains becomes sprinkled over with thin blades of grass that the summer suns soon wither. Running water, except a few rivulets, the result of the spring or autumn rains, none of which outlast the summer, there is none; but in its stead the traveller meets with a stagnant and brackish pool here and there under the shelter of some overhanging rock, or a not less brackish well. In the centre of this dreary district rises the famous mountain group, one particular summit of which, though not the highest, is conjectured to have been the Biblical Sinai. At its foot lies Wadi Feyran, a valley several miles in extent, and the only tolerably fertile piece of ground in the whole region. The climate, allowing for the increase of heat consequent on a southerly latitude, resembles in the main that of Syria,—rainy in the winter and early spring, with passing storms in autumn; at other times it is uniformly dry and clear. The summer temperature reaches in the valleys, and particularly in the great desolate gully called the "Ghowr," which is a continuation of the Dead Sea hollow, a height of 118° Fahr. in the shade; during the night it often falls to 70°, or even lower. Winter is cold, but ice and snow seldom occur except upon the heights, where the Sinai group in particular becomes snow-capped every year for a period varying from a few days to over two months. The atmosphere is healthy, except in autumn and in early spring.

Geology.

Between the gulfs of Akabah and Suez the geological formations are almost exclusively plutonic or volcanic,—the latter occupying in general a lower range than the former; metamorphic belts, chiefly of gneiss and slate, are also to be met with. Basalt and greenstone are the most usual volcanic forms, and the subterraneous action that once produced them does not yet seem to be wholly exhausted, for hot springs are of frequent occurrence throughout the region, and earthquakes, accompanied by loud underground noises, are by no means uncommon. The hot wells near Suez, called "Eyoon Moosa," or the "Fountains of Moses," are well known; as also are those entitled "Hammam Pharaoon," or the "Bath of Pharaoh," the waters of which resemble in their constituents those of the Dead Sea. These volcanic phenomena cease, however, in the zone to the east of Akabah, where rises the great and barren mountain range of Sherá (the "Seir" of the Bible), a system wholly jurassic in its composition, though its strata lie at various and often at abrupt angles.

The plants and animals tenanting this district are, with slight modifications, common to the next, where, however, they in general obtain a fuller development, and under which they may accordingly be more appropriately described.

Physical description of the Hejaz.

The second geographical district is that of the Hejaz, lying between 28° and 21° N. lat. along the eastern shore of the Red Sea, and extending inland for a distance varying from sixty to a hundred and fifty miles. It consists of a continuation of the Sherá mountain range, with a narrow sandy slip of level ground towards the sea, and a hilly plateau on the inland side, broken by bare and fantastic rocks. Its surface is, with few exceptions, barren; stony to the north, sandy to the east and south; what little irrigation it possesses is wholly from wells, deep sunk and brackish; the spring rains supply a few streams that soon dry up in summer. Along its length lie the great Syrian and Egyptian pilgrim-routes, mere camel tracks, of which the direction is determined by the scanty wells and a few villages. In the neighbourhood of Medinah alone, 25° N. lat., and at the station of Kholeys, a few days' journey north of Mecca, is any considerable cultivation to be found, the result of springs; elsewhere all is drought and sterility.

The "Haram" of Mecca.

The southernmost extremity of this region, marked off as the "Haram" or Sacred Territory, but in its physical characteristics identical with the rest, contains the town of Mecca. South-east of this tract rises the upland district called "Jebel Kora," or "Mountain of Villages," fertile and copiously watered; celebrated too for the excellence of its fruits and the salubrity of its climate; whereas the Hejaz, particularly along its western or seaward slope, has the reputation of being unhealthy and feverish. Due south of Mecca the mountains rise still higher, up to the precipitous fastnesses of Jebel Aseer, intersected by countless narrow but fertile valleys.

Geological character.

With Hejaz we may also reckon, topologically speaking, the oases of Jowf and Douma, situated to the north-east, both formed by broad and abrupt depressions in the inland plateau, and surrounded by a wide-spread wilderness of rock and sand. The geological formation of this region is chiefly calcareous and jurassic, though isolated traces of volcanic outbursts are seen near Medinah and Mecca; some also of the wells in the Hejaz—that of Zemzem, for example, at Mecca—are tepid; and one distinct eruption of lava is stated to have occurred in the neighbourhood of Medinah as recently as the middle of the 13th century.

Vegetation.

Of plants there is an endless variety, but insufficiently known, for Arab botany has yet to be investigated. "Samh," a small mesembryanthemum, from the grain of which the Bedouins prepare a sort of porridge that serves them in lieu of bread; "Mesaa," a thorny bush that bears a subacid berry not unlike a currant in appearance and flavour; "Nebek," the *Rhamnus lotus* of botanists; many kinds of euphorbia, absinthium, and the bitter colocynth, used by the Arabs for medicine, grow wild everywhere. The tamarisk or "Talh," the southern larch or "Ithel," the chestnut, the sycamore, and several other trees, the wood of which is, however, too porous and brittle for use as timber, are natives of Hejaz; so also is the wild dwarf date-palm, the almond, the pomegranate, and the "gum arabic" tree, a graceful and delicate acacia. Fine grass, intermingled with various aromatic herbs, springs up in patches between the stones and among the sand; but the want of sufficient rainfall and the dryness of the atmosphere prevent any really profitable vegetation, except in the few oases already mentioned. Taking it as a whole, the Hejaz is, with the exception of the actual and recognised desert alone, the most hopelessly sterile district in the whole Arabian peninsula.

Yemen. Following the Red Sea coast down to its southernmost extremity at Aden, we have in view the third great geographical section, that of Yemen. It includes two regions, sea-shore and inland, the former of which is commonly called the "Tehamah." This is a wide strip of coast left by the mountain chain, which, continuing on from the Hejaz, runs down as far as Aden, but hereabouts recedes somewhat to the east, thus forming an arc, in the curve of which lies the Tehamah. The mountainous district extends far inland, and gives out several minor branches, some of which reach about three hundred miles to the east.

Tehamah. Tehamah is, as might be expected from its topical and geographical conditions, a very hot region; it is one also of but moderate fertility, though the soil, an agglomeration principally of coral debris, is less absolutely barren than that of the Hejaz. The rains here are periodical, their fall coinciding with the epoch of the Indian monsoon; they give rise to numerous torrents, that traverse the plains, and some of which hardly dry up throughout the year. The coast-line is indented by several small harbours and road-steads; intricate coral reefs render the approach everywhere difficult, often dangerous.

Yemen, under which name the whole south-western quarter of the peninsula is popularly included, possesses many advantages, both of climate and soil, denied to the greater portion of Arabia. It is a highland country, formed by a labyrinth of precipitous hills and fertile valleys. The air is pure and even cool; the seasons are as regular as those of eastern India, and succeed each other in much the same order. No accurate survey has yet been made to determine the elevation of its mountains, some of which have been roughly, but perhaps incorrectly, estimated at five thousand feet in height; their general direction is from north-west to south-east. The largest plains, or rather plateaus, inclosed by them are that of Nejran on the north, that of Sanaá to the south, and that of Mareb to the east, on the frontier of the great desert. The oasis of the southern Jowf, a basin-like depression occurring in the sandy waste that reaches inland from the high grounds of Yemen up to Oman, on the other side of Arabia, may also be reckoned as belonging to Yemen.

Geology. Though the mountains are well supplied with water, no considerable rivers or streams find their way from them to the Red Sea, tropical evaporation combining with the light and porous quality of the soil to dry up the torrent beds; nor do any natural lakes exist, though artificial pools and tanks, in which water is preserved all the year round, have been constructed in plenty. Indications of volcanic action, long since extinct, abound throughout Yemen, where basalt formations compose a considerable and the most fertile portion of the coffee-bearing district; in other places jurassic rock predominates, while granite occurs in patches here and there. Spar, agate, onyx, and carnelian are exported from Yemen; silver and gold are reported to have been found on its hills, but on doubtful authority.

Vegetation. It is in this region that Arabian vegetation obtains its most varied, as also its most valuable development. North of Medinah the parched and niggard soil, chiefly composed of marl, flint, and sand, with a supply of rain alike scanty and uncertain, produces little more than varieties of acacia, euphorbias, and thorny shrubs,—a valueless crop. But in the neighbourhood of Medinah commences the great date-palm belt that crosses the peninsula, and extends southward as far as lat. 23° in full vigour. A hundred and more varieties of this tree are said to grow in the immediate vicinity of Medinah alone: the quality of the fruit varies for each kind, as also do its size, colour, and flavour. The poorest of all, the "sihanee" date, a yellow, stringy fruit, is much eaten by the Bedouins; the "birnee" is red and succulent; the "jebelee," an upland date, is a staple article of export.

The date-palm. Nejd is, however, the favoured land of date-palms: every valley that intersects its vast plateaus waves with them; and the fruit, which often attains a length of two inches, with a proportionate thickness, far surpasses the best products of Hejaz in lusciousness as in size. Eaten fresh or stewed with butter, they form the staff of Arab food; and the pulp, after the kernels have been extracted, close-pressed and half dried, is exported under the name of *ajweh* to almost every part of the East. In general a latitude varying from 27° to 22° N., and a sufficient distance from the sea to preclude its atmospheric influences, seem to be the most favourable circumstances for bringing this fruit to perfection; and hence it comes that the produce of the Jowf and of Hareek—which, though inland, lie too far, the one to the north, the other to the south,—of the Hejaz on the Red Sea, and of Rateef on the Persian Gulf coast, is decidedly inferior to that of the inland districts of Kaseem and Nejd. Yet an exception must be made in favour of the "kholas" date, as it is called, that grows in Hasa, an amber-coloured date of exquisite flavour, the king of dates: the tree itself that bears it is readily distinguished from every other species by the delicacy of its stem and foliage. But in the greater number of instances, whatever the variation in the fruit, the palm trees themselves are to an unpractised eye undistinguishable the one from the other.

Other fruit-trees. Besides the date tree, the "doom," a fan-leaved palm bearing a large fibrous and sweetish fruit, is not of uncommon growth in the central and southern districts; while the cocoa-nut and betel are planted, though not to such an extent as to reckon among the articles of ordinary cultivation, along the southern and eastern coast. So are also the banana, the papay, and the Indian fig; but all these are of recent importation from the opposite coast of India.

Vines. Vines are cultivated throughout Arabia, and have been so from time immemorial; and though since the well-known prohibition of the Koran the grapes are no longer pressed for wine, they are in great request as an article of consumption, both fresh and dried. The best fruit is that of Yemen; Oman, where the heat is such that the vintage is gathered in April, comes next, both for the quantity and the quality of its produce.

Other vegetable products. In peaches, apricots, pomegranates, and oranges, the district of Taif, near Mecca, excels all others. Senna, an article much used by the Arabs in their rough medicine, grows in the southern Hejaz and the Tehamah; so also does the balsam tree, the best of which is indigenous to the district of Safra, near Mecca; its gum is sold even within Arabia itself at a high price. The incense tree, said to be a native of Hadramaut, in the extreme south, has, strange to say, never yet been exactly identified, though its gum is a constant article of export; and the henna tree (*Lawsonia inermis*), used in dyeing, grows abundantly on the western coast. The cotton shrub springs up, seemingly wild, in the gullies of Nejd; but owing to the dryness of the soil and climate, does not repay extensive cultivation. Indigo is grown in many places, chiefly in the low districts bordering on the Persian Gulf.

Coffee. But although the Arabs themselves consider the date-palm the special pride and ornament of their country, a more general verdict would probably be given outside of Arabia itself in favour of the coffee plant. This shrub is by some supposed to be indigenous to Abyssinia; it has, however, for several centuries attained its most extensive distribution and its highest standard of produce in Yemen, where it is cultivated throughout about half of the upland district, the best quality of berry being that which ripens on the western slopes of the mountains in the neighbourhood of Sanaá.

The plant itself is too well known to require description; it is enough here to remark that its principal flowering season in Yemen is in March. The first crop of the berries ripens in May; a second and a third crop succeed in the course of the year. The diffused atmospheric heat of an equatorial region is requisite for the growth of the coffee plant; yet it needs also a large supply of moisture, and even of shade, to protect it from the too direct action of the sun. In order to obtain these conditions, large trees are often planted here and there among the shrubs, which are arranged on rock terraces, one above another, amphitheatre-wise, along the slopes, and are densely crowded together. The processes of gathering and drying the berries, of separating the husks, and of picking the kernels, are all performed by manual labour of the simplest kind. How the drink is prepared has been often and minutely described by travellers; the method employed is tedious, but the result infinitely surpasses that obtained in any other country or by any other method. A slightly acid and very refreshing beverage is also made from an infusion of the "kishr" or outer husk. Its use is almost confined to the Yemen; it is esteemed a febrifuge.

Káat shrub.

A small shrub, called "káat," is common throughout the coffee plantations; it resembles verbena in scent and growth; its leaves are chewed by the natives, much as those of tobacco are by some Europeans; the effect is that of a gentle stimulant and anti-narcotic. This plant is only found in the south-western regions, and its use is limited to them.

Hadramaut

Next to Yemen, and lying along the coast of the Indian Ocean, from Aden to Cape Ras-el-Hadd, a distance of 1200 miles, are situated the provinces of Hadramaut and Mahrah, the former mentioned in Genesis under the name of Hazarmaveth, and more celebrated in ancient Arab chronicles, and in the notices of Strabo and Ptolemy, than it has been in later times. This coast has been visited and even partially explored by Captain Wellsted and other navigators. It presents everywhere much the same dreary appearance as that of the Hejaz and Tehamah,—a narrow fringe of sand or of equally sterile shore; beyond this rises a mountain range, varying, so far as any tolerably accurate calculations have been made, from 1000 to 3000 feet in height; its formation appears to be in many places volcanic; behind this comes a second and loftier mountain belt, jurassic in its general character, resembling the highlands of Yemen; while far beyond stretches away the great sandy desert, varied, however, where it approaches the mountain-foot, by oases of considerable fertility, among which that of Wadi Doan is said to be the most extensive. Several barren islands and reefs fringe the waste. The mountains of Hadramaut form one system with those of Yemen, but, unlike the latter, seem to be of an almost monotonous sterility. Torrents descend from them, but no rivers; nor, though lakes are mentioned in the very apocryphal records of the Arabs, has any sign of their existence been verified. The climate is intensely hot, and is said to be unhealthy, at least to strangers; the vegetation is scanty. No part of the peninsula has been less explored than this, even by the Orientals themselves; and European travellers have supplied few reliable data for what regards the physical characteristics of the interior, any more than of its inhabitants and products.

Oman.

From Ras-el-Hadd to the extreme northern limits of Arabia, at the head of the Persian Gulf, the provinces of Oman and Hasa complete the sea-coast. Oman is a mountainous district, its principal range, that of Jebel Akhdar, or the "Green Mountain," so called from the abundant vegetation that covers its sides, reaches an ascertained height of 6000 feet; several other minor chains run parallel with it and with the coast; the plains beneath them are well watered and fertile, though, like every other part of Arabia, destitute of running rivers or streams, the want of which is here atoned by copious wells and springs, running over into large pools, and supplying an extensive system of irrigation. The rocks are chiefly granite on their upper, limestone on their lower level; but here, too, as on the Red Sea coast, indications of volcanic action, though at a comparatively remote period, are frequently to be observed; hot springs, too, such as those known by the title of Imam Alee, near Mascat, are not uncommon. The only good harbour on this part of the coast is that of Mascat, with which the immediately contiguous part of Matrah may be reckoned. By the sea-shore the climate is intensely hot, rivalling in this respect that of Aden, and far from wholesome; among the mountains inland the air is cool and pure.

Coast of the Persian Gulf.

Near Cape Musandam, at about 400 miles north-west of Ras-el-Hadd, the mountains (which, averaging in this promontory from 2000 to 3000 feet in height, come down in precipices to the sea edge), are indented with numerous deep creeks and bays, several of which afford good anchorage and shelter,—only they are cut off by the steepness of the surrounding cliffs from inland communication. West of Musandam, and following the sweep of the great bay of Sharjah and Katar, within the gulf itself, the coast becomes low and sandy, and henceforth offers no harbours, but mere roadsteads, often dangerous of approach by reason of the numerous banks and shoals in the sea. A few palm trees line the shore, which has a desolate appearance. Further still to the north-west, along the region of Hasa, and up to the head of the gulf, the coast continues low, but is enlivened by extensive green tracts of palm-groves and other semi-tropical vegetation. The mountains, situated a good way inland, and not exceeding 3000 feet in their extreme height, are of jurassic formation. Copious springs, some of which are hot and others tepid, break out in many places at their base, but are again absorbed in the sand, or are dissipated by field irrigation before reaching the sea. The extreme northern angle of the gulf is comparatively desert.

Physical character of the coast.

Owing to the rapid interchange of heat and cold occasioned by the peculiar situation of the gulf between the torrid levels of Arabia on the one side, and the high, not unfrequently snow-capped, mountains of Persia on the other, the climate of this coast is remarkably irregular in its seasons, and subject to sudden storms of great violence, with heavy rains. It is also decidedly unhealthy; and low fevers, sometimes of an intermittent, sometimes of a typhoid type, are never absent from the villages.

Indeed the whole of the Arabian sea-shore, which we have now thus summarily surveyed, partakes more or less of the same unhealthy character, one often noticed by travellers, and experienced by some of them with fatal effect. We have seen, too, that in general outline it offers little variety, being mostly mountainous, especially in its southern part, with a narrow and rarely fertile shore-fringe; while the mountains themselves vary in height and extent, being at their loftiest and widest in Yemen and Oman, where their rich vegetation, joined to a pure air, and a climate tempered by the elevation, offers an agreeable contrast to the dissimilar qualities of the coast itself, narrower and more barren elsewhere.

Central Arabia, or Nejd.

We have now to consider the central plateau, or Nejd, an important region, regarded by the Arabs themselves as peculiarly their own—the stronghold of their vigorous nationality, and the birthplace of their most cherished traditions and institutions.

It is girded in on every side by a broad desert belt.

which the traveller must of necessity cross before he reaches the inner region. It is this very desert that, having been often witnessed on its outer rim, but never traversed from one side to the other by Greek or Roman, or even, in the greater number of instances, by modern explorers, has given occasion to the belief that central Arabia was itself little better than an expanse of uninhabitable waste,—an idea expressed by the *Arabia Deserta* of the ancients, and often repeated by later writers.

The northern desert.

This desert, on the north and north-east, where it extends from Syria and the Hejaz inwards, is a region of hard gravelly soil, from which circumstance it has derived the elastic title of "Petræa." It is diversified here and there by belts of sand, with occasional patches of stunted bush and thin grass, indicative of moisture at some depth below; the sand, too, affords roofing for a feathery euphorbia, the "ghada" of the Arabs, a favourite browse of camels. The general height of this tract, backed up as it is by the Syrian plateau on the north, and the Sherá mountains on the west, appears to vary from 1000 to 2000 feet above the sea. Eastward it slowly slopes down to the level of the Persian Gulf. A long serpentine depression, beginning in the Syrian territory near Palmyra, traverses it in a south-easterly direction; this is Wadi Seihan, or the "Valley of the Wolf," leading to the deep oval hollow of Jowf, with its oasis of palms and gardens. A more extensive but shallower depression to the west forms the oasis of Teyma, known to Hebrew chroniclers. South of Jowf and Teyma the desert changes its stony to a sandy character, and its surface is heaped up by the winds into vast ridges, called the Nefood or "passes," not to be crossed without some danger; for, besides the almost absolute want of water, a few scanty and brackish wells of which, separated one from the other by intervals of 60 or more miles, alone exist, it is here that the

The simoom.

"simoom," or poison wind, often blows—a phenomenon entirely distinct from the customary "shelook," or sirocco, of the south, much as a hurricane differs from an ordinary gale, though the two have been occasionally confounded in popular writings. The simoom is a peculiar condition of the atmosphere, resembling in all essential points a cyclone. As in the cyclone, the central space, or the simoom itself, is calm, but is occupied by a gas unfit for respiration; while round this as a centre, slowly travelling on, there eddy violent gusts of heated air, like those of a furnace, though it is not to them, but to the comparative vacuum which they surround, that the simoom owes its suffocating qualities. It approaches slowly amid the whirl of air currents that precede it for some distance; its violet colour announces it when actually near. During its presence the only chance of preserving life till the mephitic vapour has passed over, is found in covering the face with a cloth and lying prone on the sand, thus to inhale what little atmospheric air still exists in the upper ground stratum, and thus to maintain the breath till the period, varying from two to ten minutes, of the poison column be gone by; meanwhile the feeling in the chest is that of suffocation, and that in the limbs as if molten iron were being poured over them. Camels instinctively bury their muzzles in the sand during the simoom; but horses are said not to possess the same preservatory instinct, and to perish in consequence. The precise nature of the phenomenon, and its origin, are subjects of conjecture; but its general character, that of an eddy of heated atmosphere around a central space occupied by a deleterious gas, the whole travelling at a slow rate, and generally from south or east to north and west, is not to be mistaken.

Mountains of Shomer.

South of the Nefood begins a series of granite hills, at first cropping up as mere isolated rocks through the sand, then increasing in extent and height till they coalesce and form the two parallel chains of Jebel Aja and Jebel Solma, both of which cross two-thirds of the peninsula from N.N.E. to S.S.W. The highest peak of either does not seem to exceed 4000 feet above the sea-level. Between them and around their base extend broad and well-peopled valleys. The irrigation is wholly artificial and from wells, which here yield an abundant supply. The water is brought up from an average depth of 20 or 30 feet. The climate of this region, though heated by the neighbouring desert, is remarkably healthy, and the air extremely pure.

The Kaseem.

Passing this mountain-belt, we find a second depression, still following the same general direction, namely, from N.N.E. to S.S.W., wide and fertile, a land of palm-trees, gardens, and wells; the soil is here and there streaked with sand, but no mountains or even rocks of considerable size occur anywhere. Towards the east the level of this region gradually rises upwards to the Toweyk range, by which it is ultimately shut in. Westward it slopes downwards, and at last opens out on the Hejaz near Medinah. The general level is low, not exceeding 1000 feet above the level of the sea, and the temperature hot; it is altogether the most productive, but at the same time the least healthy region of central Arabia. Water abounds throughout the greater part of its extent, at a level of only a few feet below the ground, and occasionally collects on the surface in perennial pools, none of which are, however, large enough to deserve the name of lakes. The most thickly peopled section of this valley is called Kaseem.

Mountain chain of Toweyk

North-east of it rises the mountain chain of Toweyk, running almost due south, and keeping at a distance varying from 100 to 200 miles from the Persian Gulf. This constitutes the backbone of the Arab peninsula, which rises up to it first by a rapid ascent from the coast, and then by a succession of more gently graduated plateaus and valleys from the east and west. Thus the wider half of the peninsula itself lies, not, as has been erroneously stated, to the east, but to the west of the principal watershed. The Toweyk or "complication" chain, so called from the labyrinthine character of its numerous gullies and gorges, is a broad limestone table-land, and at no point exceeds, so far as has been roughly estimated, the limit of 5000 feet in height; it covers an extent of 100 and more miles in width; its upper ledges are clothed with excellent pasturage; and its narrow valleys shelter in their shade rich gardens and plantations, usually irrigated from wells, but occasionally traversed for some short distance by running streams. Except the date-palm, the "ithel" or larch, already described, the "markh," a large-leaved spreading tree, the wood of which is too brittle for constructive purposes, and some varieties of acacia, the plateau produces no trees of considerable size; but of aromatic herbs and bright flowers, among which the red anemone or "shekeek" is conspicuous, this region is wonderfully productive,—so much that Arab writers justly praise the sweet scent no less than the purity and coolness of its breezes. The simoom or poison wind of the low lands and deserts is here unknown; even the sirocco, when it occurs, is comparatively bearable. No signs of volcanic action or hot springs are found within this region, and the mountain strata are ordinarily horizontal; the sides of the plateaus are, however, very abrupt, often forming precipices of 200 to 300 feet in height, cut out in chalky rock. These are due to water action from torrential rains that frequently fall in spring and autumn.

Physical character of the central watershed

Immediately at the foot of the eastern slope, which is much steeper than the western, lies a slip of desert, separating the highlands from the coast regions of Hassa and Kateef. The northerly part of the Toweyk plateau contains the great province of Sedeyr, the healthiest district in all Arabia: the western slope is occupied by the pro vince of Woshem, running down to Kaseem. South of Sedeyr is the province of "Ared" or "The Broad;" it includes the highest and widest table-lands of Toweyk. Thence the range trends away, taking the ordinary S.S.W. direction of the alternate elevations and depressions that furrow the Arab peninsula; here, though keeping the same geographical character, it changes its name into that of "Ared," and, like a long limestone wall, stretches almost to Mecca. Parallel to it, on the south, extends the long and barren valley of Dowasir, ending in the district of Kora, Shahrem, and Soley-yel; broken ground,—the passes of which lead to Nejran and Yemen. The upland labyrinth of Aflaj, south of Ared, forms the extreme elbow of this mountain formation. Just below it, and constituting its south-eastern slope, comes Yemamah, a hot but fertile province, with numerous wells and copious irrigation. Further yet to the south rise the fantastic peaks of the Hareek mountains, granite ridges, not over 2000 feet in height, but making up to the eye for their want of elevation by their strange abruptness: they crop out like the mountains of Shomer on the north, from the first sands of the Great Desert, and form an island, as it were, of irrigation and tillage, though both comparatively scant, and scarcely able to maintain themselves against the excessive heat amid the desolation around.

The great southern desert. Beyond Hareek, or "Burning," as the name means, to the south, as also behind Wadi Dowasir and its neighbourhood, lies the great Arab desert or Dahna, "The Red" as the Arabs call it,—a vast extent of sand, said to cover nearly 50,000 square miles, and only jotted here and there at far intervals by a few clustered bushes or dwarf palms, indicative of moisture below the surface, else wholly desolate. Its surface is ribbed into huge sand waves, the principal ones being from north to south,—that is, at right angles to the prevailing wind, which is here the east; but these main waves are again crossed, intersected, and jumbled with other less regular undulations, the work of more variable breezes.

But neither here nor elsewhere in Arabia do those clouds or columns of moving sand, the terror of caravans, appear, that have been fabled by travellers and poets. Tracks are indeed speedily covered and effaced, to the great annoyance and occasional danger of the wayfarer; but neither he nor his beast run the least risk of being thus buried alive. Hunger, and, still more, thirst, are sufficient guardians of a region, to which, however, Arab fancy has attributed the additional protection of evil spirits and monsters of death.

The Dahna. This greater desert, the "Roba el Khaliyeh" or "Empty Space" of geographers—the "Dahna" or "Crimson" of modern Arabs, so called from the prevailing colour of its heated sands,—extends to Yemen and Hadramaut on the south-west, south, and south-east, and to Oman on the east. It is separated, however, from the northern half of the waste-ring that girdles Nejd by the continuation of Wadi Dowasir and Shahran, up to the mountains of Tayef, near Mecca; and this is the only line by which the plateau of Nejd can be reached from the coast without actually crossing the sandy or stony wilderness. Lying as it does on or within the tropics, the heat of this great desert is said to be fearful by day, and, owing to the general low level, to be scarcely mitigated at night. But it is never traversed in its full width, not even by Bedouins; and little or no credit can be attached to the relations of those who pretend to have explored it, and to have found wonders in its recesses.

The Akhaf. East of Hareek rises a succession of lofty ridges, covered by a deep layer of sand, through which black rock occasionally pierces. This region bears the name of Akhaf, and connects the watershed of Toweyk with the high mountains behind Oman. It is, like the Dahna, unreclaimed desert; but the recesses of its valleys conceal a few wells and springs, so that travellers from Nejd sometimes take this route, the most difficult but the shortest, when on their way to Oman. Immediately north of the Akhaf commences the lesser Dahna, a desert resembling in every way its homonym of the south, only narrower; its breadth in many places not exceeding 50 or 60 miles. This long and dreary strip runs up the whole way along the easterly side of the Toweyk plateau, till it merges in the northern or stony waste land at the head of the Persian Gulf.

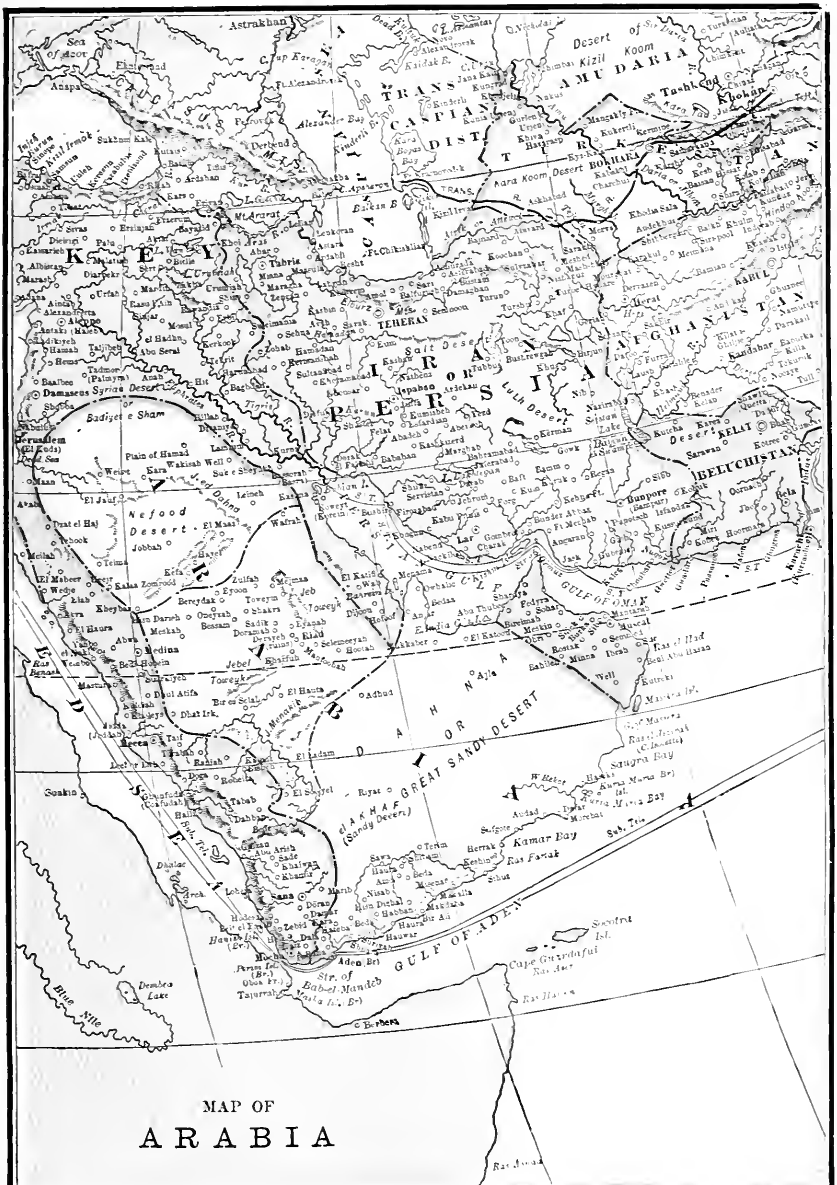
Little Dahna.

Climate of Nejd. Throughout the highlands of Nejd the climate, though often hot by day, is cool and pleasant at night; the spring and the autumn rains seldom fail in their seasons; and the soil, where not artificially irrigated, produces excellent pasture,—where irrigated, it renders very tolerable garden produce and field crops. Storms of thunder and lightning are of rare occurrence, and the tornadoes that from time to time visit the Arabian coasts are here unknown. The prevailing, as also the most refreshing winds, are from the east and north-east; the south and west winds are heated and unwelcome. Epidemic diseases are rare, and only one visitation, and that not a severe one, of cholera is on record within Nejd.

Valley of Aftan. Between Yemamah and Hareek runs the valley called Aftan, which appears in some maps as the bed of an imaginary river flowing nearly across Arabia into the Persian Gulf. But the downward slope of the valley itself is not from west to east, but in the reverse direction, and at a distance of more than 100 miles from the sea it is absolutely closed in by the sand-heaped ridges of Akhaf. Did the mountains of central Arabia furnish a water supply sufficient for a river, large or small, its course would of necessity be directed, not towards the Persian Gulf, but the Red Sea. The copious springs that break out at the foot of the Toweyk mountain range above Hasa, not far from the gulf, are all of subterranean origin; and though they are evidently the off-drainings of the rainfall of Nejd, they have no connection with the very scanty running or standing waters of the surface of the great plateau.

Summary of the geography of Arabia proper. Summing up,—Arabia may roughly be divided, as to its surface extent, into a third of coast-ring and mountains, part barren, part either cultivated or susceptible of being so; another third of central plateau, also tolerably fertile; and a third of desert circle, intervening, with only one gap, that in the latitude of Mecca, between the first and the second. The central space, whether plateau or desert, varying in height from 1000 to 3000 feet above the sea, possesses three important mountain ranges,—two transverse, namely, Jebel Shomer and Jebel Ared, and one vertical, that commences with Toweyk, and is continued by the Akhaf,—these latter being the watershed of the peninsula, the general rise of which is from west to east. The highest mountain peaks—those, namely, of Jebel Akhdar in Oman—do not apparently exceed 6000 feet.

Animals. Horse. In a description of the animals of Arabia the first place is undoubtedly due to the horse, which, though the opinion is unsupported by scientific evidence, has by some been supposed to be indigenous to the peninsula. As a fact, it is here that this animal attains its highest perfection: not, indeed, that of size; for a true Nejdee of the best and purest breed seldom reaches and never perhaps exceeds fifteen hands in height; nor that of mere speed, for a trained European racer would easily distance a thoroughbred Arab on any ordinary course; but for perfection of form, symmetry of limb, cleanness of muscle, beauty of appearance—for endurance of fatigue, for docility, and for speed maintained to distances so long as to appear incredible, the Nejdee horse acknowledges no equal. The



MAP OF

ARABIA

animal is too well known to require minute description on the present occasion; but it is important to have a clear idea of the principal divisions of its race and kind, which have been strangely and even injuriously confused by many writers.

Origin and number. Tradition assigns the origin of the present Arab stock to Yemen, but historical records, dating as far back as the 5th century, show that the best quality and the greatest number of horses were then to be found exactly in the same district where they now exist, namely, in Nejd. Yet, even there a horse is by no means an article of everyday possession, or of ordinary and working use. War and parade are in fact almost the only occasions on which it is employed; and no genuine Arab would ever dream of mounting his horse for a mere peaceful journey, whether for a short or a long distance. Hence horses are the almost exclusive property of the chiefs, who keep them for themselves, and often for the equipment of their armed retainers, and of a few wealthy or distinguished individuals, who regard them as an investment of capital or an ornament of social rank. Thus, no motive tempts the horse-owner to encourage the production of coarse and inferior breeds; while, on the other hand, every circumstance tends to render the greatest purity of blood and perfection of wind desirable; hence it is not strange that the Nejdee horse has to all appearance undergone no degeneration, though he has also probably received no improvement within historic times. Military enterprise and the centralisation of wealth and power enabled the Wahhabee chiefs of recent date to collect and rear a greater number of horses than had perhaps ever before been possessed by a single Arab potentate; and the stables and pastures of the sultan of Derey'seah may well have, as has been stated, contained 10,000 horses, since those of his much-enfeebled successor at Riad are told off at nearly half that amount. But if we allow 20,000 for the total census of pure breeds in Nejd, a full allowance, and assign an equal number to the rest of the peninsula, thus making 40,000 in all, we shall still be rather in danger of an over than of an under statement.

Breed. No distinction of breed is recognised in Nejd itself; each animal is classed according to its individual merits. Nor is a horse, nor, *a fortiori*, a mare, ever disposed of by sale; gift, war-capture, or legacy being the only recognised methods of transfer where a genuine full-blood is concerned. Consequently, no commercial export of Nejdee horses has ever been established; and whoever professes to sell or boasts of having bought one, may be unhesitatingly set down as either deceived or deceiving. In three manners, however—two occasional merely, and one customary—has the Nejdee breed been to a certain extent transplanted beyond the actual limits of Arabia.

The first of the occasional or chance means by which the horses of Nejd have from time to time found their way to foreign stables is the fortune of war. Thus, for instance, Ibraheem Pasha, after overrunning Arabia in 1817, carried away to Egypt with him several hundreds of the best Nejdees, both horses and mares; so that Egypt, though only for a while, became next to Arabia the most fortunate land in this possession; and even now, after the purity of the stock has long since been lost in the Nile valley, the effects of its transitory infusion may be distinctly traced. Next, Ibraheem's vicegerent, Khoorsheed Pasha, followed his master's example; the Ottoman Turks have been, though not often, equally lucky, and the distinctive points of Nejdee blood may now and then be observed in more than one stable at Constantinople.

Secondly, a few thorough-bred Nejdees have crossed the frontier as presents. In this manner, Teysul, the late monarch of Nejd, sent forty head from his own stable as an honorary tribute to the reigning Ottoman sultan, Abd-el-Azeez; and similar offerings have been now and then made, as fear or other motives may have dictated, to different other governments, and even to distinguished individuals. But mares are never given away thus, only stallions.

Mixed breeds. The third and customary method is by admixture of the race. Nejdee stallions are yearly hired out by their owners, and sent into the pastures of Jebel Shomer, of Syria, and even of Mesopotamia, there to breed with the mares of those countries, belonging to the Arabs of Shomer, or to the Anezeh, or the Ru'alah tribes of Syria, and the like. These mares are themselves of Arab though not of Nejdee stock; the proportion of good blood varying in them from a half up to three-fourths nearly, but none are of absolutely pure race. It is to the offspring of such by Nejdee stallions that the divisions of breed much insisted on by several European writers, and actually recognised throughout Mesopotamia and Syria, but almost, often wholly, unknown even by name in Nejd itself, apply. These divisions are principally five,—the Koheylee (said to be the purest of all), the Toweysee, the Manekee, the Saklawee, and the Julfawee; besides which, and branching out from them, there are infinite minor subdivisions. Again, these are the breeds often authenticated for purchase by written pedigrees and witness-papers of descent, as described in books; and which may occasionally be seen in Syria, but never in Arabia, or even elsewhere, when the bargain is to be concluded between two Arabs themselves. The only use of such documents is for strangers. These, too, are the breeds from which European stables, even regal and imperial, have often obtained a supply of noble but never absolutely pure-blooded animals, frequently at prices proportioned to the imagined difficulties of the purchase, or the affected unwillingness of the cunning owner—(Arabs are very cunning)—to part with his beast. The best market for these mixed breeds is at Baghdad; the second is in the neighbourhood of the town of Hama in Syria; inferior animals are sent to the port of Koweyt, on the Persian Gulf, whence they are shipped for India.

Training. To return to the genuine Nejdee. Reared under an open shed, and early habituated to the sight of men, to the sound and glitter of weapons, and to all the accessories of human life, the colt grows up free from vice or timidity, and even acquires a degree of intelligence that surprises a stranger. Barley and dates are the chief stall provender; but the grass of the pasture-grounds, in the selection of which much care is taken, is the ordinary nourishment of an Arab horse. Of water the allowance is always kept purposely scant. A good Nejdee will canter for four-and-twenty hours in summer-time, and eight-and-forty in winter, without once requiring drink. Raw meat, dried is occasionally given in small quantities when extra exertion is required; lucerne grass is employed for lowering the tone. Geldings are very rare. The colour that most frequently occurs is grey; then comes chestnut; then white and sorrel; mottled grey and black are now and then to be found; dark bay never.

Colts are ridden early—too early, indeed—in their third or even second year, and are soon broken in to a steady walk, to a canter, and to the ambling pace which is a special favourite with Arab riders; racing, an Arab amusement from time immemorial, and the game of "jerzed," a kind of tournament or mock fight with blunt palm-sticks, highly popular throughout the peninsula, complete the training both as to wind and pace. Saddles are seldom used in Nejd, and stirrups never, but both are occasionally employed in the Hejaz and Yemen. So it is also with bits, the place of which is taken in Nejd by halter-ropes, the real guidance of the animal being almost wholly effected by the pressure of the rider's leg and knee. Shoes, too, are of rare occurrence, nor are they needed in the light and sand-mixed soil of the central provinces; on the other hand, the hoofs are often rubbed with grease, to counteract the drying effects of the heated ground. Of all niceties of grooming, docking and clipping excepted, Arabs are masters, and their natural kindness to animals, a quality which they share with most Orientals, together with the care which every reasonable man bestows on a valuable article of property, ensures to an Arab horse a good treatment at the hands of his owner. But Arab horses do not commonly enter tents, nor play with women and children, nor, in a general way, do they share family meals, nor are they habitually kissed and cried over, as the imagination or credulity of some narrators has suggested. An Arab, flying for his life, has indeed been known to give the only morsel of dry bread about him to his horse rather than eat it himself,—an act in which self-preservation had probably as large a share as affection. Lastly, the standing prohibition of horse-selling from Nejd has really nothing more romantic in it than a narrow-minded application of the principles of protective monopoly; in other cases, reluctance to conclude a bargain simply indicates that the offer made was considered insufficient.

The camel. Below the horse in popular estimation and market value, but far above him in general utility so far as Arabia is concerned, comes that eminently Arab animal the camel. Of this there are many varieties: the best, swiftest, slimmest in form, and most docile to guidance, is the "hejeen," or dromedary, sometimes also called "delool," or "facile." It is almost exclusively employed for riding, whereas the "ibl," or ordinary camel, readily distinguished from the other by a coarser build, a slower pace, and a less tractable disposition, is a beast of burden, and indeed is employed for all purposes This species is very commonly, too, kept and reared for the sake of its flesh and milk, precisely as horned cattle are elsewhere; in fact, boiled camel's meat is the most ordinary article of animal food throughout the peninsula,—it is a flabby, tasteless dish, not unlike the poorest sort of beef, any flavour that it may possess is musky and disagreeable. The milk, on the contrary, is excellent, equal in quality and in sanitary properties to that of the she-ass, but neither butter nor cheese are made from it. The wool, which in the camels of Nejd and Oman is remarkably soft and fine, serves for making articles of dress, into which it is woven, sometimes alone, sometimes mixed with wool; it is much superior to sheep's wool in every respect. The ordinary colour of the animal in the northern Arab provinces is a reddish brown, but in Nejd and throughout the south, lighter tints, varying from grey to white, are more common; black is extremely rare, and highly esteemed. The least valuable breeds are those of the north and west,—that is, those of the Jowf, of Shomer, of the Hejaz, and of Yemen, in Nejd, which region, from the number of its herds, is sometimes called "Omm-el-Ibl," or "the Mother of Camels," the species improves; but all agree in assigning the palm to the dromedaries of Oman In fine, all over Arabia, whether among the Bedouins or the villagers, camels are the principal staple of traffic, the favourite investment of wealth, and the ordinary standard of property

Qualities of the camel. Camel or dromedary, the Arabian animal has only one hump, which increases or diminishes in size according to the general good or bad condition of the beast On this hump the saddle—called, if a riding one, "ghabeet," if one for baggage, "shedad"—is placed, a halter is the only rein employed, though even this is more commonly dispensed with by the Arabs, who simply direct the animal by a kick of the heel or a blow about the neck with the "mihjan," a small crooked stick carried in the rider's hand. The average travelling pace, an amble, is between five and six miles an hour, and this a good dromedary will continue for fifteen hours out of the twenty-four during a week together Six days in the summer, ten in the winter, form the longest period that the dromedary can continue his pace without a fresh supply of water, and hence an "ashavee" or "tenner" is the title given to the best of the kind. Two hundredweight is the average load of the Arab carrying camel.

No animal puts its owner to less expense for its keep: the thorns of the desert, dry grass, cactuses, euphorbias,—nothing comes amiss to a camel's appetite; a ball of paste weighing about a pound, and made of barley-meal and water, is given every evening when extra work has to be done.

The average duration of a camel's life is thirty years, that of the dromedary somewhat less; the price of either varies from about £4 to £80, according to quality, those of Oman commanding the best market. But although the camel, whether as an article of use or of sale, is far more important to Arabia than the horse, it is in intelligence and docility immeasurably inferior to the latter animal, never becoming attached to, or even, seemingly at least, acquainted with its owner, and never obeying except perforce and under protest.

Sheep. Next to camels, sheep and goats form an important item of Arab wealth. The best sheep are the piebald and large-tailed ones of Yemen; those of Nejd, too, are in great request on account of their flesh, which is excellent, though their wool is confessedly less fine in quality. Some districts of Oman produce a silky-haired breed not unlike that of Angorah. The least esteemed sheep are those of Hejaz and the north, but, in compensation, the goats of these provinces are longer-haired and generally better than those of the south; they are black, with long drooping ears. Spring is the shearing season in Nejd, but the wool is seldom exported, being mostly bought up for local use. From the milk of these animals butter and a white insipid kind of cheese are made: both are articles of daily consumption in Arab households.

Cattle. Cattle are reared throughout Arabia, but owing to the prevailing deficiency of deep and succulent pasturage their number is not so considerable as that of the camel. Cows and oxen, throughout Nejd, Oman, and Yemen, bear on their shoulders a hump analogous to the well-known one of the so-called "Brahminee" bull; the ordinary colour is dun, their legs are slender, the horns short, and the whole stature diminutive. The kine of the northern provinces are stouter and yield more milk; they have no hump. Buffaloes also are kept in the marshy districts that occur in Yemen and Oman. They differ in no respect from the Indian breed; but, unlike oxen, these animals cannot be reckoned in the ordinary list of Arab farm stock, as they exist only under exceptional circumstances, whereas a few kine may be found in almost every village, and the irrigation of the fields and gardens is mostly done by means of oxen.

Asses. Like the horse, the ass attains its greatest excellence in Arabia, where it is more often employed for riding than for loads, indeed, in some provinces, especially in Hasa, it is the usual mount even of the wealthy. The best species is that reared in Hasa and eastern Nejd, where these animals are generally of the purest white in colour, and stand from eleven to thirteen hands high. In pace they scarcely yield to an average horse. They are often exported and sold at high prices in Egypt or at Constantinople, a single animal fetching from £40 to £80. They are ridden in Arabia with side-saddles. Good asses are to be found also in the other districts of Nejd, in

Yemen, even in the Hejaz; their ordinary colour is grey. The same animal runs wild in many of the open and mountainous regions of Arabia, and is hunted for the sake of its skin by the Bedouins, but the onager or zebra of Cutch is not met with in this peninsula.

Mules. Mules and hinnies, common throughout Syria and Mesopotamia, are extremely rare in Arabia proper, where a prejudice exists against their use.

Dogs. The Arab dog differs very little from a jackal in appearance as in habits; its muzzle is pointed, its colour sandy, and its long and somewhat bushy tail is curled over the back. When domesticated, the breed improves, approaching the European wolf-dog; these animals, by training, become very tolerable indoor and out-door guardians, both of flocks and herds and of dwellings, and in this capacity they are to be found everywhere, both in the towns and villages and in the open country, where they are not less useful to their masters than annoying to strangers. Another kind of dog, belonging to the greyhound species, and evidently of exotic origin, is often reared in Arabia; the swiftest and most enduring of this kind are from the province of Hasa. They are in great favour as harriers.

Arab cats differ in no respect from their congeners in Europe except in being rather smaller. The house-mice too are absolutely the same; but the rat is more akin to the old black species of England, now nearly extinct.

Wild animals are not very numerous in any part of Arabia proper, a fact which is sufficiently accounted for by the want of running streams and open pools, as also by the thinness of cover and forest growth; yet the records of the country make mention of the existence of some kinds of beasts which have subsequently disappeared altogether. Thus the long-maned lion, and, it would appear, a large kind of ape resembling the African gorilla, often mentioned by the early writers, are no longer to be found in the peninsula. But a small tiger, formidable from its ferocity even to man, is still met with in the wild hilly regions north of Nejran, and again in the inland recesses of the Oman mountains; while the "fahd," or panther, belongs to no particular province; it haunts the neighbourhood of villages, and devours the smaller stock. Lynxes have been seen in the Hejaz and Nejd; wolves are common in the mountains, and sometimes descend to attack the flocks in the open plains. There are foxes too, but small and greyish in colour. The Arab hyæna is large and fierce; it is said, when pressed with hunger, to be dangerous even to men, and figures in many a story of Arab adventure. Jackals are more numerous in the northern than in the southern districts. Small black-faced long-tailed monkeys are to be met with by herds in Yemen, and even, though less often, in Nejd. A pretty little beast, the "yerbooa," jerboa, or kangaroo-rat, burrows in the sand, and comes out to look with great curiosity on passers-by; its hind legs, long, and provided with equally long feet and toes, are out of all proportion to the shortness of its fore-paws; its motion, especially when pursued, is like that of the kangaroo, and is performed with the help of its long sinewy tail. Its colour, partly fawn, partly white, is very agreeable to the eye. The Arabs eat its flesh, which resembles that of the rabbit.

Of the deer tribe the gazelle is the most common; it abounds not only in the open grounds, but even among the villages and near the towns. It is sometimes, but not often, hunted by the natives. Chase is more often given to the mountain goat, partly on account of its flesh, which is excellent, partly for the sake of its long recurved horns, which are like those of the Alpine steinbock, only larger. But the hare, which is coursed with dogs, and which resembles the European animal in every respect except size, for it is smaller, is the favourite game of the Arabs, who, unlike the Persians and Turks, have no scruple as to the use of the meat.

Birds. The ornithology of Arabia is copious, but has been little studied. Birds of prey, grey eagles, vultures, bustards, and sparrow-hawks, abound in the open lands; while partridges, especially of the mottled kind called "kata," are to be seen crossing the desert in quest of water by flocks; quails frequent the mountain districts in immense numbers, so also do rock-pigeons wood-pigeons, and a species of wild guinea fowl; wild ducks are met with in plenty along the coast. Cranes, larks, sparrows, finches, and the like, frequent the cultivated lands; so also does the hoopoe, a bird held in high honour by the Arabs on account of its traditional services as messenger between Solomon and the Queen of Sheba or Belkeys. A large mottled thrush, also considered to be of good omen, is seen everywhere. Flocks of swallows, the flight of which is invariably from the east, pay annual visits to Arabia, where they are very useful in diminishing the swarms of locusts, their favourite food; one species of this bird appears, however, to be indigenous to Yemen. Peacocks and parrots are also found in the southern provinces, and in Nejd, Hasa, and Oman; hawks are kept by many, and are carefully instructed for the purpose of falconry.

The ostrich. But the most remarkable bird of Arabia, and the only one which forms a regular object of chase among the natives, is the ostrich. Its extreme timidity, joined to the swiftness of its pace—for although it does not fly, it assists its running by the movement of its extended wings—renders it in vain for the hunter to attempt overtaking it on horseback; he therefore seeks to approach it generally when on its nest by artifice, and kills it by a long shot; sometimes he snares it by a running noose. The feathers, the best of which belong to the male bird, are sold at Damascus or Baghdad; the eggs are eaten, and the shells are used for ornament. The finest ostriches are those of the neighbourhood of Shomer and the uplands of Toweyk; they are often to be seen, but at a safe distance, scudding across the sands in a file of twenty or thirty at a time.

Reptiles. Reptiles, except those of the lizard species, are comparatively rare in Arabia, though serpents are occasionally met with; but, except the "afaï" and the "rukta," both snakes of the viper class, the former brown and the latter banded, and considered the deadlier of the two, none are venomous. Boa-constrictors, resembling the Indian rock-snake, have been also seen,—none, however, large enough to warrant the wonderful stories told about them by the Arabs themselves, whose love of the marvellous often leads them beyond the limits of truth.

Insects. Insects are, however, numerous enough: little scorpions, scarce an inch in length, but capable of inflicting by their sting extreme pain, swarm in the desert sands; and large ones, four or even six inches long, infest the houses. Centipedes, too, are common; wasps and wild bees tenant the rocks; flies are troublesome everywhere, and mosquitoes on the coasts; ants of all kinds, some enormous in size and venomous in bite, are to be found here; and a very poisonous spider, called, from its double pincers, "aboo hanekein," inhabits the crevices of old walls on the western coast, and is much dreaded by the natives. Scolopendras, too, are not rare. It is some compensation, however, for these serious yet only occasional inconveniences, that no fleas or bugs exist in any part of Arabia. But—a serious drawback—the "arda," or white ant, the *Termes fatalis* of Linnæus, is hardly less troublesome and destructive in the southern provinces than in India itself. Lastly, vast

Locusts. swarms of locusts, larger and darker in colour than those commonly seen further north, often infest the peninsula, and commit great ravages, especially when, as too frequently happens, their visit is in the spring or early summer. Their course is usually from east to west. However, the Arabs, by converting these insects into an article of food, make up to themselves in some measure for the damage suffered by the crops and pastures; indeed, locusts, boiled and slightly salted, are a favourite article of sale in every Arab market, but particularly in Nejd and the eastern districts.

Soil. The soil of Arabia varies according to the character of its rocky substratum. All round the coast, and to a distance corresponding with the breadth of the girding mountain chain to the interior, it is formed of volcanic and metamorphic detritus, with patches here and there of a calcareous character, due to the upheaval and decomposition of old coral banks. Such a soil cannot but be tolerably fertile, and it would be more so were the scantiness of rain made up for by a more systematic artificial irrigation. A second inconvenience is caused by the encroachments of the sand, which is at times drifted by the winds from the desert inland in such quantities as to become seriously injurious to cultivation. Behind the mountains the surface of the desert to the north and west is that of a gravelly expanse, thickly sown over with flint and quartz; while to the east and south it is an almost unalloyed waste of fine sand. Everywhere the rock underlies it, and there exists, of course, no possibility of utilising a space like this. But the whole of the central plateau—that is, of Nejd, Kaseem, Shomer, Yemamah, and the adjacent lands—is covered with a tolerably deep layer of calcareous earth, mixed with loam, well adapted for cultivation; the best is naturally to be found in the valleys and sheltered spots.

Agriculture. Whether, however, the soil be rich or poor, agriculture is, all over Arabia, very primitive in its conditions, and, above all, in its implements. The plough used by the peasants is wholly of wood and without wheels, an instrument fit for scratching rather than furrowing the ground; while in many places the earth is merely turned over with a pitchfork, which is sometimes worked by two men at a time. More skill is shown in irrigation, for whatever crop is intended, its success cannot be safely entrusted to the uncertain rain supply alone. Accordingly, the slope of the ground, whether field or plantation, is carefully calculated, and the surface divided into compartments and traversed by furrows, each communicating with the other, and all with some large well, or, in favoured situations, cistern; while in still more fortunate but rarer spots a running stream is turned to profit. But in far the greater number of instances the irrigation is from a well, with an orifice varying from six to twenty-five feet in diameter, whence the water is drawn up in large leathern buckets, to which are attached ropes passing over pulleys, and worked by mules or oxen; these buckets, on reaching a cross-beam, turn over and empty their contents into a sloping trough that runs down to the main channel of the field or garden. Green crops, vegetables, and the like, are watered, when it is possible to do so, twice a day; date-palms only once: the porous soil soon absorbs any superfluous liquid that may have overpassed the bounds assigned to it. In ascertaining the right spot for sinking a well, in digging and coating it, as also in the construction of the small cisterns often connected with the source, the Arab peasants have by long practice acquired a not contemptible skill.

Crops. The crops most common in Arabia are, first, the date, a fruit already sufficiently described; it may, however, be remarked here that the fecundation of the female trees from the male is usually perfected by art. The produce is annual: the earliest dates ripen in May, others not till July or even August. This fruit, and the dishes made of it by pressure or with butter, are to the Arabs what corn is to more northern or rice to southern nations. Next in importance, though much more limited in extent, is coffee: very little, and that of inferior quality only, is cultivated out of Yemen. This growth has also been already described in detail. Next come the following:—Wheat, a somewhat rare and not a very remunerative crop; barley, also in small quantity;—these two growths are hardly distinguishable the one from the other by the eye, the colour and shape of the ear and beard being almost identical in each. Millet is, on the contrary, largely sown, and gives an abundant return; there are several species of it; the grain, coarsely ground, is made into a sort of gruel, which appears as a daily dish in Nejd. Rice is looked on as a delicacy: it does not grow in the central uplands, but succeeds well enough in the watered coast districts, especially Hasa, Kateef, and Oman. Beans and pulse are favourite crops; they are reared in almost every part of the peninsula. Other garden plants—melons, gourds, cucumbers, salad, cabbages, onions, garlick, parsley, cumin, and the like,—are cultivated. Orchards are planted and tended in most districts; but of pruning the Arabs have little idea, though they are not unacquainted with grafting.

Husbandry. There being no true winter in any part of Arabia, the crops, such as they are, succeed each other all the year round; many lands bear twice, an early and a latter harvest, though of different produce. Of manuring, of the scientific rotation of crops, of weeding even, and clearing, the Arabs have little knowledge. Reaping is generally done with the sickle,—in some places the ripened grain is torn up by the hand; threshing is performed by oxen,—winnowing by the wind, grinding by the hand-mill. To sum up, though the agriculture of Arabia is sufficient to supply its comparatively scanty population with food, it gives almost no surplus for traffic or exportation, that of coffee and dates alone excepted.

Pasture. In pasture-land Arabia is, on the other hand, singularly fortunate. The very desert supplies through the greater part of its extent sufficient browse for camels; while the pasture-grass for horses, kine, and, above all, for sheep, on the upper hill slopes, and especially in Nejd, is first-rate. The only drawback is the occasional failure of the spring rains and autumn showers; when this occurs great distress is the result, and no commoner cause of contention and bloodshed arises between the Arab shepherds or "Bedouins" than the struggle to obtain, each for his own herd, the use of some yet undried well or exceptional oasis of green pasturage left fresh among the brown and withered herbage around.

Minerals. In mineral products of a valuable description the Arabia of our days is singularly poor, so much so as to suggest the idea that the Arabian gold and jewels, often mentioned by classical writers, must have been brought from Yemen as from a mart or depot, not a place of production. Yet even so late as 600 A.D. the exiled monarch of Sanaa, Seyf of Yezen, could in his interview with the Persian despot Chosroes, describe southern Arabia as "a land the hills of which are of gold and its dust silver." Nowadays nothing is found to justify or even to account for such gorgeous statements. Agates, onyxes, carnelians, and, though rarely, topazes alone are to be met with; of gold mines and precious ores not a trace. Lead is, however, more common. The richest ores of this mineral come from the mountains of Oman; it is brought down to Mascat, and exported thence by sea. A small quantity of silver is also extracted from the same mines. Cinnabar and iron occur in the Sinaitic peninsula, and sulphur has been observed here and there in the long volcanic range that reaches from Palestine to Mecca. Rock-salt is extracted from many parts of the coast range; it exists, too, in the central districts of the peninsula, where of metals, a little iron excepted, not a vestige appears.

The Arab coasts are much frequented by fish, many

Fisheries. of unknown species. Mackerel, mullet, sole, ray, and perch swarm in the Red Sea and Persian Gulf; nor are the sheltered spots on the long line that fronts the Indian Ocean less well provided. Sharks, too, abound along the coast, and are used as food by the poorer classes; crabs and oysters occur almost everywhere. Hence fishing forms the occupation of a large proportion among the littoral population, but ignorance of salting and curing deprives its products of export value.

Pearl fisheries. The pearl fisheries of Arabia alone add to the commercial riches of the country. They commence at the islands of Bahreyn, which lie immediately off the Arab shore, near the centre of the Persian Gulf, and continue east and south along the district of Katar for a distance of nearly 200 miles, after which the banks are lost in deep soundings. The most productive shoals are those between the islands of Halool and the coast of Katar; the fishing season commences with the spring, and lasts all through the summer. Most of the villages along the coast are wholly inhabited by divers, Arabs and negroes, who by long practice can remain under water a space of two minutes at a time; the depth they reach does not exceed fifteen fathoms, and generally falls much short of it. The oysters are opened on shore, and the pearls carefully sorted and counted by officials stationed for the purpose, as a heavy duty, equalling 20 per cent. of their value, is levied on the spot, though no further dues are taken on exportation. Some of the pearls are of great size and value. The total annual produce is roughly estimated at about £250,000, but probably exceeds that sum; a portion goes to India; another portion up gulf to Baghdad, whence it is distributed over Syria, Turkey, and Persia. The divers themselves are the worst off, as their occupation induces various congestive diseases and premature old age.

Pearls are found, too, in other bivalve shells of these seas, and are extensively sold, though at a lower price than those of the oysters. Mother-of-pearl is also common, and is an ordinary article of export, especially to Syria and Egypt; so are also occasionally the corals and ornamental shells with which these seas abound.

In mechanical arts the Arabs are, as a rule, extremely deficient, though favourable exceptions exist in some districts. The Bedouin or pastoral population know little else than the tanning of leather and the weaving of coarse fabrics, such as articles of overdress, tent coverings (which the women generally make of goat-hair), headbands, and the like. In most villages and towns of Nejd, one or more blacksmiths, whose work is of the rudest possible description, are to be found; occasionally an armourer, a few sandal-makers and workers in leather, with several weavers,—none skilled. Throughout the Hejaz these professions exist, but at a still lower standard; but in Yemen greater nicety of workmanship is to be met with; and gold and silver smiths, often, however, not Arabs but strangers by race, get a living in the towns. Formerly Yemen was celebrated for its woven stuffs; this manufacture is now, however, in anything approaching to excellence, the exclusive pride of Oman. In this last-named province, weaving, silk and gold thread embroidery, silver work, gold filigree, and even steel implements, are wrought to a degree of perfection seldom attained by the workmen even of Damascus or Baghdad; and the labours of the Oman loom or forge, when exported, as they are, though not in large quantities, are eagerly purchased abroad. But even here the extreme simplicity, or rather rudeness, of the tools employed, and the deficiency of mechanical contrivance, dwarf the results of patient and otherwise ingenious labour into comparative insignificance.

In wood the Arabs are not unskilful artificers; and their drinking bowls and platters, manufactured chiefly from the "ithel" or larch tree, and studded with small silver knobs, make a good appearance. As masons they deserve little praise; their constructions are clumsy and unstable, the details coarse and ill-fashioned. There is not a single building, public or private, built by the Arabs themselves, of any merit either in regard of utility or of beauty, within the whole of Arabia.

Trade. Backward in manufacture, and even showing, on the whole, little capacity for it, the Arabs are singularly alive to the advantages of commerce and trade, and fond of exercising them. No Arab undertakes a journey, were it only from one village to another, without taking with him some object for exchange or sale; and he will sooner chaffer away the handkerchief on his head or the camel on which he rides, than return without having effected something in the way of business. In this respect, Bedouin and townsman, rich and poor, are all alike; and their history shows that this propensity is no less ancient than universal in the race. Owing, however, to the want of variety in its productions, and the remarkably uniform habits of its inhabitants, combined with the scarcity of local manufactures, the trade of Arabia, whether export or import, is soon catalogued. Camels and sheep, hair and wool, come first on the export list; next coffee; then dates, then horses; a very little rice and a few cloaks from Yemen or Oman close the chapter of commerce so far as land produce is concerned; pearls sum up that of the sea. Nor is the import much more diversified or extensive. Cotton cloth, Indian prints, sugar, a little hardware, a few arms, powder and shot, and trinkets of no great value—such are the customary requisitions of the land. Nor has any single Arab, the Imam or Prince of Mascat alone excepted, sufficient available capital for extensive traffic, out or in; while the Mahometan prohibition of interest, and consequently of credit, joined to the illegality of insurance, would, even in a richer land, restrict enterprise within very unsatisfactory bounds. It is owing, indeed, to these narrow-minded laws, introduced by the Koran and co-existent with its observance, that what commerce exists at the seaports of Hejaz, Tehamah, and Yemen, has mainly fallen into the hands of Jews and Banians—that is, Indian merchants; though in Oman, where a more liberal spirit prevails, Arab merchants of considerable capital and with extensive connections are to be found. The custom-duties in the ports of Oman and the Persian Gulf, whether export or import, are 10 per cent., except on pearls; in the harbours of Yemen they are capricious, and often very high. The shereef or governor of Mecca used formerly to carry on, through Jiddah, a trade hardly inferior to that of the Imam of Mascat himself; but the devastations committed by the Wahhabees, and in later times the oppression of the Egyptian and Turkish governments, have considerably reduced this source of Arab income.

Origin of Arab race. The origin of the Arab race, like that of most others, can only be matter of conjecture; no credit can be attached to the assertions, evidently unbased on historical facts, of those authors who, building on the narrow foundation of Hebrew records, have included the entire nation under the titles of Ishmael and Joktan; and Mahometan testimony on these matters can have no more weight than the Jewish, from which it is evidently derived. Setting, therefore, these vague and half-poetical traditions aside, the first certain fact on which to base our investigations is the ancient and undoubted division of the Arab race into two branches, the "Arab," or pure; and the "Mostareb," or adscititious. The geographical limits of both branches have already been sufficiently indicated. A second fact is, that everything in pre-Islamitic literature and record—the only reliable authorities in such a case, as preserved to us in the *Hamasa*, the *Kitab-el-Aghanee*, the writings of Musáoodee and Abul-

Feda, the stories of Antarah or Mohalhet, and the like—concurs in representing the first settlement of the "pure" Arabs as made on the extreme south-western point of the peninsula, near Aden, and thence spreading northward and eastward over Yemen, Hadramaut, and Oman. A third is the name Himyar, or "dusky," given now to the ruling class, now to the entire nation; a circumstance pointing, like the former, to African origin. A fourth is the Himyaritic language—now, indeed, almost lost, but some words of which have been preserved either in proper names or even in whole sentences handed down. They are African in character, often in identity. Indeed, the dialect commonly used along the south-eastern coast hardly differs from that used by the Somawlee Africans on the opposite shore; but later intermixture of blood and constant intercourse may have much to do with this. Fifthly, it is remarkable that where the grammar of the Arabic, now spoken by the "pure" Arabs, differs from that of the north, it approaches to or coincides with the Abyssinian. Now, it is well known to philologists that grammatical inflections are a much more abiding and intimate test of origin than separate nouns or even verbs. Sixthly, the pre-Islamitic institutions of Yemen and its allied provinces—its monarchies, courts, armies, and serfs—bear a marked resemblance to the historical Africo-Egyptian type, and even to the modern Abyssinian. Seventhly, the physical conformation of the pure-blooded Arab inhabitants of Yemen, Hadramaut, Oman, and the adjoining districts—the shape and size of the head, the slenderness of the lower limbs, the comparative scantiness of hair, and other particulars—point in an African rather than an Asiatic direction. Eighthly, the general habits of the people,—given to sedentary rather than nomade occupations, fond of village life, of society, of dance and music; good cultivators of the soil, tolerable traders, moderate artisans, but averse to pastoral pursuits—have much more in common with the inhabitants of the African than with those of the western Asiatic continent. Lastly, the extreme facility of marriage which exists in all classes of the southern Arabs with the African races; the fecundity of such unions; and the slightness or even absence of any caste feeling between the dusky "pure" Arab and the still darker native of modern Africa—conditions different from those obtaining almost everywhere else—may be regarded as pointing in the direction of a community of origin. Further indications are afforded both by local tradition and actual observation; but they are of a nature to be scarcely appreciable, except by those whom long familiarity has rendered intimate with the races in question; besides, the above are, for average criticism, sufficient.

Origin of Mustareb race.

It is harder to determine with precision the origin of the "adscititious" or "Mustareb" Arabs, and the circumstances under which they first peopled their half of the peninsula. Though in physical, mental, and lingual characteristics they offer too marked an affinity with the Arabs of the south to allow of any supposition except that of ultimate unity, so far as the stock is concerned; yet they present many and important divergences from them, and these divergences, whatever their nature, have all an Asiatic impress of their own. Such are their pastoral tendencies and proneness to nomade life; such the peculiarities of their idiom, drawing near to the Hebrew; such the strong clannish feeling, joined with a constant resistance to anything like regal power or settled comprehensive organisation; such even the outward and physical type. Time after time we may observe—in their history, their literature, their institutions or the absence of them, their past, their present—traits now Hebrew, now Syrian, now Chaldæan, now even Tatar; though the groundwork of the whole is undoubtedly identical with the Arab of the south. The probability, faintly indicated by tradition, is that at an early, indeed an absolutely pre-historic period, this branch of the Arab race, emigrating eastward, passed into Asia—not like their congeners, at the southern, but at the northern or isthmal extremity of the Red Sea; then pursued their inland way to the plains of Mesopotamia and Chaldæa, and perhaps even further; and after a long sojourn in these lands, during which they acquired the modifications, mental and physical, which distinguish them from their southern and more unchanged brethren, returned westward to the land already partly occupied by their kinsmen. This return would not be effected all at once, but by band after band, according to the pressure exercised on them by Iranian or Turanian neighbours, a fact witnessed to by many of the northern pre-Islamitic traditions, as found in Ibn-Atheer, Tabreezee, and others; while the well-known Ishmaelitic mythos, recorded alike in Hebrew and in Arab chronicles, probably points to the last batch of "adscititious" Arab immigrants, the special clan from which the family of Koreysh and the Prophet had origin.

Once established on the same soil, the two branches would naturally early manifest a tendency to unite, sufficient in time to produce a tolerable identity both of language and of usages; while the superinduced modifications of character and manners may well have originated the rivalry and even enmity between the Arabs of the north, or "Keysees," and those of Yemen, which, under various forms, has never ceased down to our own time.

Actual divisions of the Arab race. Bedouins.

At present, however, the most important, as also the best-known division of the Arab race is that which separates them into "Ahl Bedoo," or "dwellers in the open land," whence the common appellation of Bedouin; and "Ahl Hadr," or "dwellers in fixed localities." The former class, living under tents, and occupying the waste country which lies in a vast circle between the coast and the central plateau, while to the north it joins on to the Syrian desert, are the best known to European travellers, with whom they often come in contact, and by whom they have sometimes been described with considerable exaggeration both as to their numbers and in other respects. The most trustworthy authorities regarding them are Niebuhr and Burckhardt.

Mode of life.

The Bedouins, then, are shepherds and herdsmen, reduced to an out-of-doors and roving life, partly by the intrinsic nature of their occupations, partly by the special characteristics of the country they belong to. For, while land, unsuited to all purposes except pasture, forms an unusually large proportion of the surface in the Arabian territory, the prolonged droughts of summer render considerable portions of it unfit even for that, and thus continually oblige the herdsmen to migrate from one spot to another in search of sufficient herbage and water for their beasts. The same causes also involve the Bedouins in frequent quarrels with each other regarding the use of some particular well or pasture-ground, besides reducing them not unfrequently to extreme want, and thus making them plunderers of others in self-support. Lastly, the loneliness of the desert, far removed from the vigilant control of fixed law, order, or police, has, combined with the other circumstances, continued during generation after generation to leave a peculiar impress on a naturally bold, hardy, and enterprising race, till the terms Bedouin and brigand have, in the opinion of many, become synonymous.

Habits.

This opinion is, however, unjust. Professionally, and in the ordinary course of their lives, Bedouins are only shepherds and herdsmen: their raids on each other, or their exploits in despoiling travellers and caravans, are but occasional, though welcome and even exciting, exceptions to the common routine. Besides, their wars or forays among themselves,—for they very rarely venture on a conflict with the better armed and better organised sedentary population,—are rarely bloody; the object being most often with the one party to carry off, and with the other to protect, a flock of sheep or a herd of camels: booty is aimed at, not slaughter. If positive hatred or a desire to kill exist, such feelings are usually limited to two or three individuals at most, one of whom has perhaps been ridiculed in satirical verse, to which they are very sensitive, or had a distant relation killed in some previous fray. Bloodshed, too, is expensive, as it must be made up for either by more bloodshed or by paying the price,—the "deeah," as it is called, and which varies, according to the importance of the person killed, from ten to fifty camels, or even more. Previous to Mahomet's time it was left optional to the injured tribe either to accept this kind of compensation or to insist on blood for blood; but the Prophet, though by his own account despairing of ever reducing the nomade portion of his countrymen to any fixed observances, succeeded on this point in establishing among them the rule, that a fair "deeah," if offered, must of necessity be accepted: a merciful regulation, tending to cut short otherwise interminable feuds.

Instances are, however, not wanting in Arab history of fiercer and more general Bedouin conflicts, in which the destruction, or at least the complete subjugation, of one tribe has been aimed at by another, and when great slaughter has accordingly taken place. Such were the wars of Pekr and Thagleb in the 6th century, of Kelb and Howazin in the 8th, of Harb and Oteybah in the 18th, with others. But these are comparatively rare events.

Brigandage. The Bedouins regard the plundering of caravans or travellers, whether on business or otherwise, simply as a supplementary measure that takes the place of passports or custom dues exacted elsewhere. The land is theirs, they say, and trespassers on it without leave must pay the forfeit. Hence whoever can show anything equivalent to a permission of entrance into their territory, has, in the regular course of things, nothing to fear. This permission is obtained by securing the protection of the nearest Bedouin sheykh, who, for a politely-worded request and a small sum of money, will readily grant the pass, in the shape of one or two or more men of his tribe, who accompany the wayfarers as far as the next encampment on their road, where they hand their charge over to fresh guides, equally bound to afford the desired safeguard. In the interior of the peninsula the passport is given in writing by one of the local town governors, and is respected by the Bedouins of the district; for, however impudent and unamenable to law these nomades may be on the frontiers of the impotent Ottoman government in Syria or the Hejaz, they are quiet and submissive enough in other and Arab-governed regions of the peninsula. But the rash traveller who ventures on the desert strip without the precautions above mentioned is likely enough to atone for his negligence by the loss of his luggage; and should he resist, perhaps his life also.

Tribes. Utterly ignorant of writing and unacquainted with books, the Bedouins trust to their memory for everything; where memory fails, they readily eke it out with imagination. Hence their own assertions regarding the antiquity, numbers, strength, &c., of their clans are of little real worth; even their genealogies, in which they pretend to be eminently versed, are not to be much depended on; the more so that their own family names hardly ever exceed the limits of a patronymic, whilst the constantly renewed subdivisions of a tribe, and the temporary increase of one branch and decrease of another, tend to efface the original name of the clan. Few tribes, accordingly, now preserve their ancient, or at least their historical titles; and the mass of the Bedouin multitude resembles in this respect a troubled sea, of which the substance is indeed always the same, but the surface is continually shifting and changing. As, however, no social basis or ties are acknowledged among them except those of blood and race, certain broad divisions are tolerably accurately kept up, the wider and more important of which may here be noted.

Anezah. First, the Anezah clan, whose pasture-grounds extend from Syria southward to the limits of Jebel Shomer. It is numerous, and, for a Bedouin tribe, well armed. Two-thirds of the Arab horse trade, besides a large traffic in sheep, camels, wool, and similar articles, are in the hands of these Anezah Bedouins. Their principal subdivisions are the Sebaá on the north, the Woold-Alee on the west, and the Ruála on the south; these are generally on bad terms with each other. If united, they could muster, it is supposed, about 30,000 lances. They claim descent from Rabeeah. Shomer. Second, the Shomer Bedouins, whose pasturages lie conterminous to those of the Anezah on the east. Their numbers are about the same. Howeytat. Thirdly, in the northern desert, the Howeytat and Sherarat, comparatively small and savage tribes. Also the Soleebee clan, which, however, is disowned by the Arabs, and seems to be of gipsy origin. Harb. Next follow, in the western desert, the Benoo-Harb, a powerful tribe, supposed to muster about 20,000 lances. Their origin is from Keys-Eylan. They are often troublesome to the Meccan pilgrims. Moteyr. In the eastern desert are the Moteyr, the Benoo-Khalid, and the Ajmans, all numerous clans, often at war with each other. Others. To the south, in Nejd itself or on its frontiers, are the Hodeyl, Oteybah, and others. These all belong to the "Mustareb," or northern Arabs.

Southern Bedouins. The Bedouins of southern or "pure Arab" origin are comparatively few in number, and are, it seems, with few exceptions, even poorer and more savage than their northern brethren. Al-Morrah, on the confines of Oman, Al-Yam and Kahtan, near Yemen, and Benoo-Yas, between Hareek and the Persian Gulf, are the best known. The total number of the Bedouin or pastoral population throughout Arabia appears, including men, women, and children, not to exceed a million and a half—it may even fall short of it.

Organisation. Whatever be the clan, the only authority it submits to is that of its "elder," or "sheykh," a title which, however, does not necessarily imply advanced age, but is given to any one who, on account of birth, courage, wealth, liberality, skill, prudence, or some other fortunate quality or accident, has been chosen to the leadership. Descent has something to do with rank, but not much, as every individual of the tribe considers himself equal to the others; nor are the distinctions of relative riches and poverty greatly taken into account. This is natural in a state of things where property itself, consisting almost wholly of live stock, is of an essentially uncertain and fluctuating character, and the Bedouins have no other. To the "sheykh" all disputes are referred; he is consulted, though not necessarily obeyed, on every question which regards the general affairs of the tribe, whether in peace or war; there is no other magistrate, and no law except what he and the other chief men of the clan may consider proper. But in fact, for most personal and private affairs, every man does pretty much what is right in his own eyes.

Religion. Nominally Mahometan, most of the Bedouins pay slight attention to the ceremonial precepts of the Koran; the five daily prayers and the annual fast of Ramadhan are not much in favour among them; and however near a tribe may be to Mecca, few of them visit it as pilgrims. Wahhabee influence exercised, sword in hand, has, however, of late enforced some degree of Islamitic observance among the Bedouins of Nejd and the adjoining districts: elsewhere nomade Mahometanism is pretty nearly confined to the profession of the Divine Unity; among the remoter and wilder tribes sun-worship, tree-worship, and no worship at all, are not uncommon. Some clans even omit the rite of circumcision altogether; others, like the tribe of Hodeyl, south of Mecca, perform it after a fashion peculiar to themselves.

Morals.

Nor are the social and moral injunctions of Islam better observed. Marriages are contracted without any legal intervention or guarantee; the consent of the parties, and the oral testimony of a couple of witnesses, should such be at hand, are all that are required; and divorce is equally facile. Nor is mutual constancy much expected or observed either by men or women; and the husband is rarely strict in exacting from the wife a fidelity that he himself has no idea of observing. Jealousy may indeed occasionally bring about tragic results, but this rarely occurs except where publicity, to which the Bedouins, like all other Arabs, are very sensitive, is involved. A maiden's honour is, on the other hand, severely guarded; and even too openly avowed a courtship, though with the most honourable intentions, is ill looked on. But marriage, if indeed so slight and temporary a connection as it is among Bedouins deserves the name, is often merely a passport for mutual licence. In other respects, Bedouin morality, like that of most half-savage races, depends on custom and public feeling rather than on any fixed code or trained conscience, and hence admits of the strangest contradictions. Not only are lying and exaggeration no reproach in ordinary discourse, but even deliberate perjury and violation of the most solemn engagements are frequent occurrences. Not less frequent, however, are instances of prolonged fidelity and observance of promise carried to the limits of romance. "The wind," "the wood," and "the honour of the Arabs," are the most ordinary oaths in serious matters; but even these do not give absolute security, while a simple verbal engagement will at other times prove an inviolable guarantee. Thus, too, the extreme abstemiousness of a Bedouin alternates with excessive gorgings; and, while the name and deeds of "robber" are hardly a reproach, those of "thief" are marked by abhorrence and contempt. Patience, or rather endurance, both physical and moral, few Bedouins are deficient in; wariness is another quality universally developed by their mode of life. And in spite of an excessive coarseness of language, and often of action, gross vice, at least of the more debasing sorts that dishonour the East, is rare among them. Of their hospitality, as also of many other points common between them and the town Arabs, we shall speak further on.

Personal appearance. In person most Bedouins, men or women, are rather undersized, the result probably of hardships endured through uncounted generations; their complexion, especially in the south, is dark; their hair coarse, copious, and black; their eyes dark and oval, the nose is commonly aquiline, and the features well formed; beard and moustache are apt to be somewhat scanty. The men are active, but not strong; the women, rarely otherwise than plain.

Dress. Their dress is simple enough; that of the men consisting in a long cotton shirt, open at the breast, and often girt with a leathern girdle; a black or striped cloak of hair is sometimes thrown over the shoulders; a handkerchief, folded but once, and generally black, more seldom striped yellow and red, covers the head, round which it is kept in its place by a piece of twine or a twisted hairband. To this costume a pair of open sandals is sometimes added. No other article of dress is worn,—neither trousers nor turban, but under the shirt, round the naked waist, a thin strip of leather plait is wound several times, not for any special object, but merely out of custom. In his hand a Bedouin almost always carries a slight crooked wand, commonly of almond-wood; with this he guides his camel when on the road, and amuses himself by playing with it at other times. Among the Bedouins of the south a light wrapper takes the place of the handkerchief on the head, and a loin-cloth that of the shirt.

Women's dress. A woman's attire is hardly more complicated; wide loose drawers, though these are sometimes dispensed with; next a long shirt, and over it a wide piece of dark blue cloth enveloping the whole figure, the head included, and trailing on the ground behind. Very rarely does a Bedouin woman wear a veil, or even cover her face with her overcloak, contenting herself with narrowing the folds of the latter over her head on the approach of a stranger. Her wrists and ankles are generally adorned with bracelets and rings of blue glass or copper or iron, very rarely of silver; her neck with glass beads; earrings are rare, and noserings rarer. A few comparatively rich women indulge in more elegant ornaments and fuller dress. Boys, till near puberty, usually go stark naked; girls up to six or seven.

Weapons. On a journey a Bedouin invariably bears with him a light sharp-pointed lance, the stem of which is made of Persian or African cane; the manner in which this is carried or trailed often indicates the tribe of the owner. The lance is the favourite and characteristic weapon of the Arab nomade, and the one in the use of which he shows the greatest skill, throwing it, at need, to a considerable distance with unerring aim. Frequently, too, he girds on, or rather suspends from a kind of shoulder-belt, a sword, straight or crooked as may be; the blade is often of little value, rusty, and not over sharp; the scabbard of wood. The weapon which comes third in frequency is a gun; this is still in almost every instance a matchlock, clumsy and foul, taking from five to ten minutes to load and fire, when, indeed, it can be fired at all, which is not always the case. Yet with such wretched implements at his disposal, a Bedouin is seldom other than a good marksman. Flint-guns may here and there be met with now-a-days; but percussion or breech-loaders never. Nor are pistols any part of a Bedouin's war equipment. But whether in peace or war, he is seldom without a knife: this in the north is only a large clumsy clasp or sheath knife; but in Yemen, Oman, and the intervening regions it develops into a broad and crooked dagger, a truly formidable weapon, on the ornamentation of which the Bedouin of the south bestows what skill or wealth he may happen to possess.

Armour. For defensive armour a Bedouin on a foray, or preparing for a serious engagement, sometimes puts on a coat of mail, the manufacture of Yemen or Baghdad; its links are thin, but closely plaited, and often are two or even three deep. To this he adds a helmet, a mere iron head-piece, without visor or crest. Pennons and banners are rarely used by the nomades, whose chief tactics consist in surprise, as their main object is plunder, both of which require, not display, but secrecy. For though the Bedouins are undoubtedly brave and reckless enough of life, their own as well as that of others, where a cause requires it, they have the good sense never to venture blood unnecessarily or on insufficient grounds. Indeed on all points and in all their dealings, shrewd, calm, good sense, joined with a humorous and sarcastic turn of mind, may be said to be the base of their character, their passions, strong and lasting, are kept in habitual control; and in these regards, as in a lively and poetical imagination, and a wonderful power of untaught eloquence, they resemble their more settled countrymen of the towns and villages. In their principal faults, too—instability, restlessness, envy, rancour, untruthfulness, and sensuality—they resemble them also.

Independence Much has been said and written of the independence of the Bedouins, and of their having never submitted themselves to a foreign yoke; and prophecy has been called in to explain a fact which a little reflection would have shown to imply nothing marvellous or exceptional whatever, but to be merely the natural result of condition and circumstances. A nomade population, thinly scattered over a large and open space of meagre pasture-land, will always be unconquerable, because it offers next to nothing to conquer. When in camp, a Bedouin's tent consists of a few coverings of the coarsest goat-hair, dyed black, and spread over two or more small poles, in height from 8 to 9 feet, gipsy fashion. If it be the tent of a sheykh or man of consequence, its total length may be from 30 to 40 feet; if of an ordinary person, it will oftener fall short of 20. Sometimes a partition separates the quarters allotted to the women and children; sometimes they are housed under a lower and narrower covering. A piece of rough carpet or an old mat may or may not be spread on the sandy floor; while camel-saddles, ropes, halters, and the like, constitute the entire furniture of the dwelling; ornament there is none. To the list two or three cauldrons for cooking, one or two platters, and a wooden drinking bowl, must be added; and with these, including the master's arms in one side of the tent, and his spear stuck in the ground at the door, the household valuables are complete. When the time comes for moving, all these several articles are easily fastened in bundles on the backs of one or more camels; the men mount their saddles, the women their litters; and in an hour the blackened stones that served for a cooking hearth remain as almost the only sign where the encampment has been. When the tribe is once on its way across the desert, pursuit is difficult; and were the fugitives overtaken, they would offer nothing to repay the trouble of their pursuers. It may be worth the while of nomades such as these occasionally to plunder each other, but it can hardly be worth the while of any foreign power to plunder, still less to attempt to subdue them, and in this lies the whole secret of their imagined independence.

Settled Arabs

From the Bedouins, or "Ahl Bedoo," we now turn to the "Ahl Hadr," or the dwellers in fixed abodes. These constitute about six-sevenths of the population of Arabia proper, and it is from them alone that a just appreciation of the Arab character and customs can be formed.

Family divisions.

Though the clan and the family form the basis and are the ultimate expression of the civilised Arab society, they do not, as is the case among the Bedouins, sum it up altogether; local feelings and duties, the consequences of settled life having deeply modified the character alike of the individuals and the race among all Arabs, town or country. Still, blood is the first thing taken into account; and, indeed, the possession of written records, and habits of order and reflection, enable the settled Arabs to acquire and retain a more accurate knowledge and nicer distinction of pedigree and race than could be expected or found among the unreflecting and half-barbarous Bedouins.

Koreysh.

Throughout the peninsula, but especially on the western side, the family of Koreysh is even yet regarded as the noblest of Arab races, indeed of the world; and its members, on the strength of their connection with the Prophet, all bear the title of "Shereef," sometimes also, as in Yemen, that of "Seyyid," or "lord." Besides the advantages which naturally follow popular respect, they hold in several districts of Arabia—in Mecca itself, for example, in Aboo-Areesh, and in some parts of Yemen—the positions and emoluments of local hereditary governors. But they do not assume any regular distinctive mark, like the green turban so often worn in Turkey or Persia; nor in private life do they enjoy any immunity, either explicit or prescriptive, from the ordinary obligations of law.

Titles of rank—Sheykh.

"Sheykh," or elder, "Emeer," or ruler, "Imam," or preceder, and "Sultan," or monarch, are personal and often, though not necessarily, hereditary titles of rank. "Walee," or governor, is a word the use of which is limited to Yemen and Oman. "Sheykh," on the contrary, is universal; every village, however small, every separate quarter of a town, has a "sheykh," in whom is lodged the executive power of government—a power loosely defined, and of more or less extent according to the personal character and means of the individual who wields it. A village "sheykh" is a sort of head magistrate and chief of police, or like a sheriff of old times. His power is, however, occasionally limited, particularly in towns, by that of the "kadee," or "judge," whose duty consists in the official, though rather arbitrary, interpretation of the law, and whose sentence ought, in theory at least, to precede the action of the sheykh. But as the Koran, the sole authentic authority in all matters, legal or civil, throughout Arabia, never accurately distinguished between the two classes, and its phrases, besides, are vague and capable of admitting different and even opposite interpretations, the administration of law and justice has in consequence always remained extremely irregular, and dependent much more on the personal good sense and integrity of the officials, or too often on their want of those desirable qualities, than on any methodised system. The sheykh has no fixed income; he is usually a landed proprietor, sometimes a merchant; many sheykhs, however, abuse their power for their own private advantage. Nor is his office strictly hereditary, though it may become accidentally so.

Emeer

Emeer is a higher title, restricted to a governor of a district or province especially in Shomer, Nejd, and the rest of the central region. An emeer is in most respects nothing but a magnified sheykh; he has, however, the advantage of drawing a considerable portion of his income from the country he administers. Thus in Nejd the emeers receive and retain, partially in Wahhabee governments, wholly in others, the "zekat," or tithes, varying from one-twentieth up to one-fifth of the value of property, besides other occasional dues, fines, &c.; in Hasa, Bahreyn, Katar, Mahrah, and Hadramaut the emeer can also claim the fishery tax and customs. Beyond Wahhabee limits he has the ordinary, within them the extraordinary, power of life and death; in all cases he can punish by imprisonment and fine. Part of his office is to hold public audiences daily, on which occasions every one who chooses, of whatever rank or condition, has the right of coming forward and of presenting any complaint or petition. Sometimes the emeer takes the matter thus brought before him into his own hands at once; sometimes he refers it to the radee, or to the elder and more respectable inhabitants, who in these meetings take seat near the emeer, and form a kind of improvised council. The emeer himself wears about him no distinctive badge of office; nor is he approached with any ceremony beyond that of ordinary Arab politeness. In the Wahhabee provinces, or those where Wahhabeeism, though no longer dominant, has made a permanent impression, as in Shomer for instance, the emeer commonly takes on himself the duties of the Friday "imam," not unlike those of precentor in Presbyterian worship, in the public mosque; now and then he preaches a sermon. His position is generally hereditary, but not always in direct line.

Sultan.

The title of "sultan," or king, one of doubtful antiquity, has been assumed by the hereditary Wahhabee ruler of Riad, the capital of Nejd; it is also often applied to the sovereign of Oman, and to some petty princes in the south of the peninsula. In practice it adds little or nothing to the dignity of emeer, but implies a larger territorial range of authority.

Religion.

Where the Wahhabee doctrines have definitely established themselves, as in Nejd, Yemameh, Hareek, Aflaj, and Jebel Aseer, the Mahometan code, as laid down in the Koran, is observed more strictly perhaps than in any other part of the Eastern World. Besides the principal mosque, or "jamiá," for Friday prayers, indispensable in every town or village, smaller praying-places, or mesjids, are erected in every quarter. These buildings are mere oblong rooms, flat-roofed, supported on numerous rough pillars placed close to each other, and with no architectural or decorative beauty whatever; but are kept scrupulously clean, and laid down partly with mats, partly gravel. In most cases there is no minaret attached, the times of prayer being merely announced by the "múeddin," or crier, from the roof itself. Punctuality in attendance is enforced by the "mutowwás," or "compellers" of "obedience," a set of self-elected zealots, who parade the towns and villages with sticks in their hands, take note of the defaulters from prayers, or transgressors otherwise of the letter of the law, and punish them with reproaches or even blows. Marriage, divorce, inheritance, purchase, every detail of life is regulated in exact accordance with the Koran; even conversation is liable to censure unless thickly interlarded with words of religious import; while after night-prayers talking is a luxury prohibited altogether. Yet, though these Wahhabee Arabs are bigoted even to fanaticism among themselves and with their fellow-countrymen, they are remarkably tolerant towards strangers, and often unite with the extreme of theoretical exclusiveness a good deal of the practical scepticism and indifference common to their race.

Orthodox sects. These Wahhabees all belong to the orthodox sect of Ebn-Hanbal, and are in fact its most exaggerated expression. In the eastern provinces, Hasa, Katee, Bahreyn, and Katar, the Malikee sect is more common; as also, it is said, in Hadramaut, and in some parts of Yemen. But in Yemen generally, and throughout the Hejaz, the Shaféyee sect, orthodox like the two others, predominates. There are no Hanefees in Arabia, except a few Turks or Indians settled on the western coast. "Sheéah," too, or votaries of Ali and his family, in the Persian sense of the word, are by no means common in the peninsula, and where found are often of foreign origin.

Khowarij. But all along the Persian Gulf, in Hasa, Bahreyn, and Katar, a considerable proportion of the inhabitants are not Mahometans at all, that is, in the ordinary acceptation of the word, but "Khowarij," or "seceders," belonging to the Karmathian school already mentioned; while in Oman, the little peninsula or cape of Ras-el-Rheymah excepted, where Wahhabeeism has made good its footing, the bulk of the people belong to the Beyadee or Abadee sect, a Karmathian offshoot nearly allied in doctrines and in practice to the "Ismaileeyah" of Syria. For a detailed account of either the reader may with advantage consult Silvestre de Sacy's admirable treatise on the "Batineeyah," or secret sects of the Mahometan East, prefixed to his History of the Druses. Somewhat akin to these, but of a less marked divergence from orthodox Islam, are the Zeydees, of whom great numbers exist in Yemen. Lastly, paganism, or rather the fetichism that takes for its scope a stone, tree, or some other natural object, appears to exist in Mahrah, in the southern Jowf, and in various small half-isolated spots on the borders of the great desert, or Dahna. Vestiges of Sabaism, or the worship of the heavenly bodies, are said to linger among the wilder Bedouin tribes, who even yet compute the year from the rising of Soheyl or Canopus, and prostrate themselves to the morning sun. It is also noticeable that even such of the southern Arabs as are professedly Mahometan, are far less zealous and much laxer in their ways than the Arabs of the north; in fact, the Islam of the latter was indigenous, that of the former acquired or compulsory.

Except in a few places on the west coast long exposed to Egyptian, Turkish, and Indian influences, no dervishes are to be met with, or are even tolerated, in Arabia proper. The Wahhabees all hold them in the utmost contempt and abhorrence. Nor are Arabs, generally speaking, superstitious in other respects: of dreams and omens they make little account; nor does the apprehension of ghosts, spectres, apparitions, demons, and the like often disquiet their hours of loneliness or darkness; stories of such a character, though embodied here and there in Arab literature, in the *Thousand and One Nights* for example, are less frequently of Arab than of foreign origin, generally Persian. Nor do Arabs often seek to convert others, except it be their own purchased negro slaves, a facile acquisition, to Mahometanism, or molest those of other religions. Jews exist undisturbed in great numbers near Teyma and in the south; Hindoos worship cows and burn their dead without interference in Oman; only old custom, it would seem, and the memory of long and bitter wars, prohibits the practice of the Christian religion in Arabia proper,—Aden alone, of course, where the British flag proclaims absolute tolerance, excepted. Absence of superstition.

Slavery is still, as of old times, a recognised institution throughout Arabia; and an active traffic in blacks is carried on along the coasts of the Persian Gulf and the Red Sea, but especially the former. Slavery.

The slaves themselves are chiefly brought from the east African coast districts down as far as Zanzibar, and from the Galla tribes in the interior; a few Abyssinians, too, are sometimes imported. Slaves are usually employed in Arabia as herdsmen or as domestic servants, rarely in agricultural works; they also form a considerable portion of the body-guards with which Eastern greatness loves to surround itself. Like their countrymen elsewhere, they readily embrace the religion of their masters, and become zealous Mahometans, though rarely according to knowledge. Arab custom enfranchises a slave who has accepted Islam at the end of seven years of bondage; and when that period has arrived, the master, instead of exacting from his slave the price of freedom, generally, on giving him his liberty, adds the requisite means for supporting himself and a family in comfort. Further, on every important occasion, such as a birth, circumcision, a marriage, or a death, one or more of the household slaves are sure of acquiring their freedom. Hence it comes that Arabia is densely sprinkled with a free black population; and these again, by intermarriage with the whites around, have filled the land with a mulatto breed of every shade, till, in the eastern and southern provinces especially, a white skin is almost an exception. This has taken place all the more readily that in Arabia there exists no prejudice against negro alliances; no social or political line separates the African from the Arab. A negro may become a sheykh, a kadee, an emeer, or whatever his industry and his talents may render him capable of being. This occurs frequently, particularly in Nejd, Yemen, and Hadramaut; in the Hejaz and the north, on the contrary, a faint line of demarcation may be observed between the races.

Both town and village Arabs are, as a rule, serious in gait and demeanour, and very observant of politeness, not only in the manner, but even in the substance of their conversation. In temper, or at least in the manifestation of it, they are studiously calm; and an Arab rarely so much as raises his voice in a dispute. He prides himself on an unruffled exterior, and will bear much with careful seeming calm that would drive a European to the extreme of impatience and rage. But this outward tranquillity covers feelings alike keen and permanent; and the remembrance of a rash jest or injurious word, uttered years before, is too often the cause of violence and bloodshed. Character.

Besides, however, the individual shades of character, there exist marked tribal or almost semi-national diversities, among the Arabs. Thus, the inhabitants of Hejaz are noted for courtesy and blamed for fickleness; those of Nejd are distinguished by their stern tenacity and dignity of deportment; the nations of Yemen are gentle and pliant, but revengeful; those of Hasa and Oman cheerful and fond of sport, though at the same time turbulent and unsteady. Anything approaching to a game is rare in Nejd, and in the Hejaz religion and the yearly occurrence of the pilgrim ceremonies almost exclude all public diversions; but in Yemen the well-known game of the "jereed," or palm-stick, with dances and music—the latter very barbarous, it must be allowed—is not rare. In Oman such amusements are still more frequent. Again, in Yemen and Oman, coffee-houses, where people can resort for conversation, and where public recitals, songs, and other diversions are to be met with, stand open all day; while nothing of the sort is tolerated in Nejd. So it is also with the ceremonies observed on occasion of circumcision or marriage—occasions of gaiety and pastime on the coast, but passed over with little of the like observance in the central provinces.

Arab towns. An Arab town, or even village, except it be the merest hamlet, is invariably walled round; but the ramparts are low, and seldom of any stronger material than dried earth; they are occasionally flanked by towers of like construction, such as befit a country where cannon are unknown and fire-arms are yet at the matchlock stage. A dry-ditch often surrounds the whole. The streets are utterly irregular—some broad, some narrow, all tortuous; the houses are of one or two storeys, very rarely of three, with flat mud roofs, little windows, and no external ornament. If the town be large, the expansion of one or two streets becomes a market-place, where are ranged a few shops of eatables, drugs, coffee, and, very rarely, cottons or other goods. Many of these shops are kept by women. The chief mosque is always near the market-place; so is also the governor's residence, which, except in size and in being more or less fortified Arab fashion, does not differ from a private house. Drainage is unthought of; but the extreme dryness of the air obviates the inconvenience and disease that under other skies could not fail to ensue, and which in the damper climates of the coast make themselves seriously felt. But the streets are roughly swept every day, each householder taking care of what lies before his own door. Whitewash and colour are occasionally used in Yemen, Hejaz, and Oman; elsewhere a light ochre tint, the colour of the sun-dried bricks, predominates in an Arab town or village, which looks at a distance like a large dust-heap in the centre of the bright green ring of gardens and palm-groves all around. Baked bricks are unknown in Arabia, and stone buildings are rare, especially in Nejd. Palm branches and the like, woven in wattles, form the dwellings of the poorer classes in the southern districts. Many Arab towns possess watch-towers, like huge round factory chimneys in appearance, built of sun-dried bricks, and varying in height from 50 to 100 feet, or even more. Indeed, two of these constructions at the town of Birket-el-Mawj, in Oman, are said to be each of 170 feet in height, and that of Nezwah, in the same province, is reckoned at 140; but these are of stone. Some of these watch-towers are so built as to serve also for citadels or places of refuge; but none could offer a minute's resistance to any kind of artillery, though formidable obstacles to men whose only means of attack are lances and matchlocks.

Interior of an Arab dwelling. The principal feature in the interior of an Arab house is the "kahwah," or coffee-room, as from its destination it is commonly called. It is a large apartment spread with mats, and sometimes furnished with carpets and a few cushions. At one extremity is a small furnace or fire-place, for preparing coffee. In this room the men congregate; here guests are received, and even lodged; women rarely enter it, except at times when strangers are unlikely to be present. Some of these apartments are very spacious, and supported by pillars; one wall is usually built transversely to the compass direction of the káabeh; it serves to facilitate the performance of prayer by those who may happen to be in the kahwah at the appointed times. The other rooms are ordinarily small, and appropriated to the use of the females of the family and to domestic life.

Hospitality. In hospitality the Arabs of our time have in no degree degenerated from their former reputation, though Shomer, Nejd, Yemamah, and Hasa excel in this respect the other provinces. A stranger's arrival is often the occasion of an amicable dispute among the wealthier inhabitants as to who shall have the privilege of receiving him; and though three days are often popularly spoken of as the limit of such entertainment, practice sets no precise bounds to its length; and an Arab host always carefully abstains from putting any question to his guest as to when he is going, or where. Indeed, if the guest be discreet and acceptable in his manners, he will soon find himself on the footing of one of the family; and even the women of the house will come in to sit and converse with him not less freely than they would with their own relations.

Cookery. Arab cookery is of the simplest. Roughly-ground wheat cooked with butter; bread, in thin cakes, prepared on a heated iron plate or against the walls of an open oven; a few vegetables, generally of the leguminous kinds; boiled mutton or camel's flesh, if the circumstances of the host allow of such luxuries; dates and fruits,—this is the *menu* of an ordinary meal. Roast meat, fried, stewed—in a word, anything but boiled—is rarely seen, such dishes exceeding the skill of the cooks, who, as a rule, are the women of the household. Rice is eaten in wealthy houses, and fish is common on the coasts. Among the Bedouins, millet-cakes, half-cooked in ashes, or a broth prepared from the gritty seeds of the "samh" (a species of *Mesembryanthemum*), often take the place of bread; and their meat cookery is equally wretched. Game, such as venison, partridge, and hare, is served up on rare occasions. Camel meat is a favourite, but to a stranger a very insipid dish, in southern Nejd, Yemamah, Hareek, and Aflaj. Spices are freely employed in town cookery; butter much too largely for a European taste.

Entertainment. After eating, the hands are always washed with soap, or some substitute for it, commonly the ashes of an alkaline plant. A covered censer with burning incense is then passed round, and each guest perfumes his hands, face, and sometimes his clothes; this censer serves also on first receptions, and whenever special honour is intended. In Yemen and Oman scented water often does duty for it. Coffee, without milk or sugar, but flavoured with an aromatic seed brought from India, is served to all. This, too, is done on the occasion of a first welcome, when the cups often make two or three successive rounds; but, in fact, coffee is made and drunk at any time, as frequently as the desire for it may suggest itself; and each time fresh grains are sifted, roasted, pounded, and boiled—a very laborious process, and one that requires in the better sort of establishments a special servant or slave for the work. Among the Bedouins the use of coffee is rare, though they are fond of it when they can get it. Arabs in general make only one solid meal a-day—that of supper, soon after sunset; nor even then do they eat much, gluttony being rare among them, and even daintiness esteemed disgraceful. Wine, like other fermented drinks, is prohibited by the Koran, and is, in fact, very rarely to be met with, though the inhabitants of the mountains of Oman are said to indulge in it. On the coast spirits of the worst quality are sometimes procured; opium and hasheesh have also but few votaries in Arabia. On the other hand, wherever Wahhabeeism has left freedom of action, tobacco-smoking prevails, the manner of smoking varying considerably, according to the district. Among the Bedouins and the poorer classes of the upland regions a short pipe of clay, called a "sebeel," red or black, is in vogue. The wealthier townsmen prefer long pipes with large open bowls; but the most frequent use is made of the water-pipe, or "narghileh," of which implement every form, kind, and dimension imaginable may be found in Arabia. The tobacco smoked is generally strong, and is either brought from the neighbourhood of Baghdad or grown in the country itself. The strongest quality is that of Oman; the leaf is broad and coarse, and retains its green colour even when dried; a few whiffs have been known to produce absolute stupor. The aversion of the Wahhabees to tobacco is well known; they entitle it "mukhzee," or "the shameful," and its use is punished with blows, as the public use of wine would be elsewhere.

Smoking.

Dress. In dress much variety prevails. The loose cotton drawers, girded at the waist, which in hot climates do duty for trousers, are not often worn, even by the upper classes, in Nejd or Yemamah, where a kind of silk dressing-gown is thrown over the long shirt; frequently, too, a brown or black cloak distinguishes the wealthier citizen; his head-dress is in its character the same as that of the Bedouins — namely, a handkerchief fastened round the head by a band—only of better materials. But in Hejaz, Yemen, and Oman, turbans are by no means uncommon; the ordinary colour is white; they are worn over one or more skull-caps—sometimes fifteen—till the head is rather burdened than protected. Trousers also form part of the dress in the two former of these districts; and a voluminous sash, in which a dagger or an inkstand is stuck, is wrapped round the waist. Meanwhile the poorer folk and the villagers often content themselves with a broad piece of cloth round the loins, and another across the shoulders. In Oman trousers are rare, but over the shirt a long gown, of peculiar and somewhat close-fitting cut, dyed yellow, is often worn. The women in these provinces commonly put on loose drawers, and some add veils to their head-dresses; they are fond of ornaments (gold and silver), and overcharge themselves with them; their hair is generally arranged in a long plait hanging down behind. All men allow their beards, whiskers, and moustaches full growth, though none of these are much to speak of, particularly among the Arabs of the south, who are a thin-haired race. Most shave their heads, and indeed all, strictly speaking, ought by Mahometan custom to do so; but many, peasants especially, Bedouins, and the like, neglect it. An Arab seldom or never dyes his hair. Sandals are worn more often than shoes, but the heat of the ground in the day-time allows none except the very poorest to go wholly barefoot. Lastly, though no class or occupation lays claim to any particular style or article of dress, legists, writers, imams, and others connected with the service of the mosques, generally affect greater amplitude and less variety of colour in their turbans and vestments than other people.

Personal appearance and qualities. In person the Arabs are a remarkably handsome race,—tall, lithe, well-formed, dark-eyed, and dark-haired. Deformed individuals or dwarfs are rare among them; nor, except leprosy, of which frequent instances may be met with throughout the peninsula, does any disease seem to be hereditary among them. The frequency of ophthalmia, though not in the virulent Egyptian form, is evidently attributable to the nature of the soil and the climate. They are scrupulously clean in their persons, adding to the prescribed ablutions of the Mahometan code frequent supererogatory washings of their own; and take special care of their teeth, which are generally fine, though toothache is by no means unknown in Arabia. Simple and abstemious in their habits, they often reach an extreme yet healthy old age; nor is it common among them for the faculties of the mind to give way sooner than those of the body. To sum up, physically and morally they yield to few races, if any, of mankind; mentally, they surpass most, and are only kept back in the march of common progress by the remarkable defect of organising power and incapacity for combined action which they share with many other nations of the East, and some, it would seem, of the West also. Lax and imperfect as are their forms of government, it is with impatience that even these are borne; and we have already seen that of the four caliphs who alone reigned—if reign theirs could be called—in Arabia proper, three died a violent death; and of the Wahhabee princes, the most genuine representatives in later times of pure Arab rule, almost all have met the same fate.

Revenues. Of the revenues of Arabia it would be difficult to form anything like a correct estimate. Palgrave has stated the yearly receipts of the Nejdean treasury, inclusive of the tribute then (1862) paid into it by Bahreyn and the west of Oman, to be nearly £106,000 sterling—no very large sum.

The revenues of Oman itself, then in a comparatively prosperous condition, are estimated by the same author at nearly ten times the amount, but may possibly have been overrated by him, as those of Yemen were perhaps by Niebuhr. Certainly the general condition of these provinces—the restricted character of the cultivation and the evident poverty (not absolute want, indeed, for that is rare) of the greater number of the inhabitants—do not convey to the visitor the idea of large national wealth or extensive resources. There can, however, be no doubt that both the coast districts of Arabia, in their varied and valuable products, and the central plateau, with its palm-groves, well irrigation, and wide pasture-lands, might, under a judicious administration, become the sources of much greater revenues, both public and private, than is now the case. The mines, too, in the metamorphic districts of Yemen and Oman, remain yet to be properly worked. As for the desert proper, which, as we have seen, occupies about one-third of the peninsula, it must, like the ocean of *Childe Harold*, remain what it is to the end of time.

Defence. In the 7th century Arabia sent forth armies that attacked and conquered nearly half the then known world. But the secret of her conquests lay not in the number of her warriors, but in a resolute purpose, a unity of aim, and an enthusiasm which concentrated in itself and intensified every motive of human action. In later ages she has been reduced to the defensive, and has shown herself not always equal even to that: witness her conquest by the Turks in the 16th, and by the Egyptians in the present century. Once only, at the moment when Wahhabee union and zeal half restored for a few years the energy of early Islam, did her armies go forth to invade the neighbouring territories of Mesopotamia and Syria; but it was to plunder rather than to conquer, and the results lasted no longer than the invasions themselves.

Yet on the defensive Arabia had much in her favour, and that from many causes. The first is, that there is little to defend, since, the coast of Yemen and the districts of Bahreyn and Oman excepted, there is very little to excite the cupidity of an invading, and nothing to satisfy the exigencies of an occupying force. The second is, that the mountainous nature of Yemen and Oman themselves, and the narrowness of their labyrinthine defiles, added to the extreme heat of the climate, and the scarcity of available provisions, would make even those provinces hard to attack, harder to retain. A third cause is in the broad strips of desert that gird the central districts as with a moat of sand, and send long arms of barrenness here and there into the heart of the cultivated or pastoral regions, so as to render military operations on a large scale in the interior almost impossible. A fourth and a very serious obstacle to invasion is the character of the inhabitants. Personal courage, wonderful endurance of privation, fixity of purpose, and a contempt of death rare even in the bravest Europeans, are qualities common to almost every race, tribe, and clan that compose the Arab nation; and though their undisciplined troops are unfitted to meet a better trained enemy in a regular battle, in skirmishing and harassing they have few equals, while at close quarters their individual impetuosity often disconcerts the more mechanical fortitude of organised regiments. To this our own troops gave testimony in the engagements of Shenaz, 1810, and of Ras-el-Hadd, 1819 and 1820, when, with swords and spears alone, the Arabs of Oman maintained a desperate struggle against guns and bayonets, neither giving nor receiving quarter. **Military tactics.** Nor are they wholly ignorant of tactics, their armies, when engaged in regular war, being divided into centre and wings, with skirmishers in front, and a reserve behind, often screened at the outset of the engagement by the camels of the expedition. These animals, kneeling, and ranged in long parallel rows, form a sort of entrenchment, from behind which the soldiers of the main body fire their matchlocks, while the front divisions, opening out, act on either flank of the enemy. This arrangement of troops may be traced in Arab records as far back as the 5th century, and has often been exemplified during the Wahhabee wars in our own day.

Military force. The military contingent of Nejd, including that of all the adjoining provinces that constitute central Arabia, Jebel Shomer excepted, is reckoned by Palgrave at 47,300 from among the settled, and at about 8000 from among the nomade inhabitants. That of Shomer is estimated by the same authority at 14,000 of the first, and at about 16,000 of the second category. Oman, including the neighbouring and allied districts, is said to supply about 112,000, all from towns or villages.

We thus obtain a total of about 197,300 fighting men for what represents a full half of the Arab peninsula. If, therefore, we calculate the entire military force of the land from Suez to Aden, and from the Red Sea to the Indian Ocean, at 400,000 fighting men, we shall probably be not far from the truth. But while remembering, on the one hand, that this is no standing army, nor composed of regular and disciplined soldiers, it should not be forgotten that, in case of invasion, their energy, and, it may be, their numbers, would be doubled by the enthusiasm of patriotism; and that not every male only, but every woman would, in the excitement of the struggle, take part in the national defence.

Courage of Arab women. Indeed, at all times Arab women have distinguished themselves by their bravery hardly less than Arab men. Records of armed heroines occur frequently in the chronicles or myths of the pre-Islamitic time; and in authentic history the Battle of the Camel, 656 A.D., where Ayeshah, the wife of Mahomet, headed the charge, is only the first of a number of instances in which Arab amazons have taken, sword in hand, no inconsiderable share in the wars and victories of Islam. Even now it is the custom for an Arab force to be always accompanied by some courageous maiden, who, mounted on a blackened camel, leads the onslaught, singing verses of encouragement for her own, of insult for the opposing tribe. Round her litter the fiercest of the battle rages, and her capture or death is the signal of utter rout; it is hers also to head the triumph after the victory of her clan.

Education. There is little education, in our sense of the word, in Arabia. Among the Bedouins there are, of course, no schools, and few, even of the most elementary character, in the towns or villages. Where they exist, little beyond the mechanical reading of the Koran, and the equally mechanical learning of it by rote, is taught. On the other hand, Arab male children, brought up from early years among the grown-up men of the house or tent, learn more from their own parents and at home than is common in other countries; reading and writing are in most instances thus acquired, or rather transmitted; besides such general principles of grammar and eloquence, often of poetry and history, as the elders themselves may be able to impart. To this family schooling too are due the good manners, politeness, and self-restraint that early distinguish Arab children. In the very few instances where a public school of a higher class exists, writing, grammar, and rhetoric sum up its teachings. Law and theology in the narrow sense that both these words have in the Islamitic system, are explained in afternoon lectures given in most mosques; and some verses of the Koran, with one of the accepted commentaries, that of El-Beidawee for example, form the basis of the instruction.

Dialects. Great attention is paid to accuracy of grammar and purity of diction throughout Arabia; yet something of a dialectic difference may be observed in the various districts. The purest Arabic, that which is as nearly as possible identical in the choice of words and in its inflections with the language of the Koran, is spoken in Nejd, and the best again of that in the province of Sedeyr. Next in purity comes the Arabic of Shomer. Throughout the Hejaz in general, the language, though extremely elegant, is not equally correct; in Hasa, Bahreyn, and Oman, it is decidedly influenced by the foreign element called Nabathæan, that removes it still further from its original character. In Yemen, as in other southern districts of the peninsula, Arabic merges by insensible degrees into the Himyaritic or African dialect of Hadramaut and Mahrah. The Arabic spoken by the nomade or Bedouin tribes, especially those of the north, is tolerably correct, but the pronunciation is often inexact.

Territorial divisions. The principal territorial divisions of Arabia have been already indicated, but a detailed list may here not be out of place. They are, accordingly, on the western side—

Hejaz. The Hejaz, subject in great measure to Ottoman authority, and extending from 28° to 21° N. lat. Its principal towns are YAMBO and JIDDAH on the sea-coast, MEDINAH and MECCA in the interior; all of which are separately described in the articles under these headings. The inhabitants are partly nomade, partly settled, in about equal proportions. The Hejaz includes the Beled-el-Haram, of sacred territory, immediately adjoining Mecca; and the Táif, a mountainous but fertile district to the S.E. of that town.

Jebel Aseer. Jebel Aseer, a mountainous tract along the coast immediately south of the Hejaz. Its inhabitants are of the Wahhabee sect, and are governed by their own sheykhs, with an emeer residing at Kolakh, the principal town or rather village of the region. The Turks have lately invaded it, but to no great purpose.

Aboo Areesh. Aboo Areesh, along the coast, from 17° 40′ to 15° 50′ N. lat. This district, now occupied by the Turks, detached itself from Yemen about a century ago. Its inhabitants live in villages: the soil is poor, but the fisheries abundant.

Tehamah. Tehamah. This name is given to the shore strip from 15° 50′ to Aden, 12° 47′ N. lat. Its principal towns are Loheya, Hodeydeh, and Mokha; the two former of these are seaports, of 4000 or 5000 souls each; the last is celebrated for its export of coffee, but its population does not exceed 8000 souls at most. There are numerous fishing villages along the coast, and some inland hamlets; the district is now partially occupied by the Turks.

Yemen. Yemen. Under this title are included thirty mountain districts, dependent on the "imam" or prince of Yemen, who resides at Sanaá, the capital, a town which is said, in the extent of its edifices and gardens, to have once rivalled Damascus, but which at present scarcely contains 20,000 inhabitants. It is surrounded by turreted walls, with seven gates: the mosques, public baths, and market place are all modern. Inland there are several small independent states, accurately enumerated by Niebuhr, the best, or rather the only authority for what regards this part of Arabia. In extent Yemen constitutes about one-tenth of the superficies of the peninsula. It is thickly peopled throughout, with countless villages; the nomades are few in number. It has been recently invaded by the Turks.

Jowf, a large oasis in the desert, adjoining Yemen on the east. It contains the ancient capital of south Arabia, Mareb, with the ruins of the famous dyke that bears its name, besides many villages. The inhabitants are warlike; the country is said to be fruitful, but little is known of it with certainty, nor has any European ever visited it.

Nejran. Nejran, an independent province on the north-east of Yemen. It is fertile and thickly peopled; the inhabitants are mostly villagers, and belong to a sect allied to that of the Beyadees in Oman. The principal town, situated on the highroad of Sanaá, bears the same name as the district.

Adjacent districts. Kaláat-Bisha, Shahran, Kahtan, Taslees, Belad-el-Kobeyel, and others—small districts, each governed by its own sheykh, except the last named, of which the inhabitants are chiefly nomade; the others are agricultural. They are situated to the east and north of Yemen, on the confines of Nejd.

Hadramaut. Hadramaut, an extensive region, occupying the south-east coast and inland. Niebuhr, our best authority for this part of Arabia, as for Yemen, describes it as being divided into several small principalities, of which Shibam on the south, and Ainad further north, are the chief. The only towns really known are Dafar and Kesheen, ports of the coast; they are both small and unimportant. The inhabitants are all governed by their own chiefs. Of their race and language mention has been made before; their mode of life is partly nomade, partly settled.

Mahrah. Mahrah, a continuation of Hadramaut northwards, up to Ras-el-Hadd. Its inhabitants, who appear to be the least civilised among all the Arab races, pay an irregular allegiance to the sultan of Oman. The country is said to be sandy, and thinly peopled; the Bedouin tribes of Al-Morrah and Aboo-Alse frequent its pasturages.

Northern. Returning inland, we find the north and centre of Arabia thus divided:—

Jowf. Jowf, an oasis south of the Syrian frontier. It contains seven principal and some smaller villages. The population is set down at 40,000 souls; they are governed by an emeer, who depends on the prince of Shomer.

Teyma. Teyma, a thinly-peopled district west of Jowf. Its inhabitants are mostly Bedouin, and each clan obeys its own sheykh. The total population is 12,000.

Kheybar. Kheybar, a collection of small villages and encampments on the north-west of the Hejaz; several of the tribes inhabiting it are of Jewish origin. The population is given at 25,000.

Jebel Shomer. Jebel Shomer, an important province, including the mountain ranges of Aja and Solma south of Jowf. Its capital, Hayel, stands on the highroad between Bosrah and Medinah; it possesses a public market-place, and may contain about 15,000 or 16,000 souls. The villages of the province are forty; the total population 162,000, who are given to agricultural and pastoral pursuits in about equal proportions. The emeer or prince is hereditary, and allied with, though not dependent on, the government of Nejd.

Upper Kaseem. Upper Kaseem, an oblong strip of land, lying between the mountains of Shomer and the valley of Lower Kaseem, which latter belongs to Nejd. The soil is sandy, but not unfertile. It contains about twenty villages, besides many hamlets. The population is stated at 35,000. This district is subject to the emeer of Shomer.

Bedouins. The principal Bedouin tribes of this part of Arabia are the Shomer, who indeed have given their name to the province; the Shcrarat; the Howeytat; the Benoo-Ateeyah; the Máaz; the Téy, a very ancient and famous tribe, of southern origin, whose emigration hither dates from many centuries before Mahomet; and the Wahhideyah. The total population is estimated at 166,000 souls; but this does not include the Bedouins of Teyma and Kheybar, who together, it is said, muster an equal number.

There remains Nejd, a name including the whole central inhabitable district of Arabia, and which is divided into nine provinces. They are as follows:—

Ared, the centre province, in which the present Wahhabee capital, Riad, is situated. The town is very ancient, and has a population of 30,000. It possesses a palace, where the sultan of Nejd resides, and many other considerable buildings. The fortifications are extensive, but of unbaked brick only, as are also the dwellings of the town; near Riad may still be seen the ruins of the ancient capital, Dereyéeah, demolished by Ibrahim Pasha in 1817. Besides Riad, Ared contains many villages so large as to merit the name of towns; the land is generally fertile, cultivation abounds, and the total population exceeds, it is said, 100,000.

Sedeyr, an extensive province, north of Ared, and situated in the highlands of the Toweyk mountain chain. Its principal town, Mejmaá, is fortified, Arab fashion; the ancient towns, Jelajib, Toweym, and others are situated here. The number of large villages is twenty-five; the entire population is 140,000. They are a brave and intelligent race, and furnish the choicest contingent to the Wahhabee armies.

Yemamah. Yemamah, a fertile district, south of Ared, celebrated in all ages of Arab history for the bravery of its men and the beauty of its women. It forms an important part of the Wahhabee empire. Its principal town is Manfoohah; but it includes many others, such as Khorj, the neighbourhood of which, from its fertility, is called the paradise of Nejd; the number of inhabitants is said to equal that of Sedeyr.

Hareek. Hareek, a mountainous oasis on the extreme southern verge of Nejd, at the commencement of the great desert, or Dahná. Principal town, Hootah. The inhabitants are all zealous Wahhabees; their number is stated at 14,000. The villages are 16 in number.

Aflaj. Aflaj, a small and hilly district south-west of Ared. The inhabitants are Wahhabees, and number 16,000; the villages, of which Kharfah is the chief, are twelve in all.

Wadi Dowasir. Wadi Dowasir, a long shallow valley, reaching down from Aflaj in the direction of Yemen; the soil is sandy and unproductive. It contains fifty small villages, besides hamlets, and the population is estimated at 100,000, all Wahhabees. They have a bad reputation for illiberality and meanness of disposition.

Soleyel. Soleyel, also a Wahhabee province. It forms the junction between Wadi Dowasir and Yemen; its principal town bears the same name as the district. Its villages are given at twenty-five, its inhabitants at 30,000.

Woshem. Woshem, a small, compact, but important district west of Ared, of which it is the key. Its principal town, Doramah, offered a determined resistance to Ibraham Pasha in 1817. Here, too, is Shakrah, a large commercial centre; Kowéy, near which was fought the decisive battle between the Egyptian and Wahhabee troops; and other villages, twenty in all. Inhabitants, 80,000, all Wahhabees. The country is well supplied with water, and the ground productive.

Kaseem. Kaseem, a wide fertile valley west of Woshem, and belonging to the Wahhabee government. It possesses three large towns—Onezzah, Bereydah, and Rass—besides about 60 villages and numerous hamlets. The inhabitants are a busy and thriving, but not a very warlike race; they are computed at 300,000. These districts constitute Nejd proper, and form the bulk of the present Wahhabee monarchy.

Hasa. Coming now to the east coast, we find Hasa, a large province occupying almost the whole region conterminous with the upper half of the Persian Gulf. Its principal town, Hofhoof, possesses a remarkable fortress, said to be of Karmathian construction, besides a large market-place and several handsome buildings. Close by is the more modern town of Mebarrez, almost equalling the capital itself in size. The province is in general well-watered and fertile; the number of villages about fifty, that of the population 160,000. This region belongs to the Wahhabee government, but has lately been occupied by the Turks.

Kateef. Kateef, a small, marshy, but fertile district on the shores of the Persian Gulf, directly opposite to Bahreyn. It belongs, like Hasa, to the Wahhabees; the principal town, also called Kateef, was once the residence of the dreaded Karmathian princes. The climate is unhealthy; the population is estimated at about 100,000 souls.

Bedouins. The most considerable nomade tribes in this district are the Ajman, Benoo-Hajr, Benoo-Khalid, Méteyr, Oteybah, Sebaá, Kahtan, Harb (a numerous and warlike clan), Anezeh, and Al-morrah. Their whole number does not probably exceed 80,000; the nomade population of central Arabia bearing no proportion to the settled, whereas a reverse condition exists on the northern frontier, and above all in the Syrian desert.

Continuing our review of the eastern districts, we next find—

Bahreyn. Bahreyn, a name given to the two large islands of Menameh and Moharrek, both celebrated for pearl fisheries off their shores. They are governed by a chief of their own, of the family name of Khaleefah; but pay an uncertain allegiance, sometimes to the government of Baghdad, sometimes to that of Oman. Numerous villages cover the islands, of which the soil is fertile; but the chief resources of the inhabitants are maritime and commercial. Population, 70,000.

Katar. Katar, the pearl-fishery coast east of Hasa. Its inhabitants, said to be 135,000 in number, find an almost exclusive occupation in the pearl trade; inland the region is barren and desert. This province depends on the chiefs of Bahreyn, but it also pays tribute to Oman.

Sharjah. Sharjah, a coast strip, with a seaport of the same name, east of Katar. It belongs to Oman, but has been often occupied by the Wahhabees. Sharjah is a great depot for slaves brought from the east African coast; the inhabitants are mostly concerned in the trade. The province counts thirty-five villages and 85,000 inhabitants. The present governor, Khalid-ebn-Sakar, whose authority also extends over the two next districts, is almost independent of the sultan of Mascat.

Roos-el-Jebal. Roos-el-Jebal, also known as the Jowasimah, or Private Coast. The chief village, Rás-el-Kheymáh, was destroyed by the English in 1810, and again in 1819; although since rebuilt, it has ceased to be a nest of robbers. This coast is very mountainous, and the inhabitants, mostly Wahhabees, are savage in the extreme. Their number is said not to exceed 10,000; they speak a dialect of their own, almost unintelligible to the Arabs of the neighbourhood.

Kalhat. Kalhat, the coast region east of Cape Mesandom. Its principal village is the small seaport of Leemah; the other hamlets are about forty in number. The population, a rough seafaring set, is stated at 60,000.

Batineh. Batineh. This district includes the whole plain between the mountains of Oman and the sea-coast as far as Ras-Heyran, east of Mascat. It is the richest, best-watered, and most thickly populated in all Arabia, and contains several considerable towns, of which Mascat is the chief; and where the sultan, or, as he is sometimes called, imam, of Oman resides. The other principal towns are Matrah, Barkah, Sohar, and Shenaz, all seaports of some activity along the coast; more than seventy other small towns and villages are reported to be scattered through the interior. The population, all Biadeeyah, and mortal-enemies of the Arabs of Nejd, is said to be 700,000.

Dahirah, the north-western province of Oman, having for its principal town that of Bereymah, besides several places of less importance. It is the only district where the nomade population bears any proportion to the settled: the total population is given at 80,000. The Wahhabees of Nejd have often occupied and still continue to harass this part of the country.

Jebel Akhdar. Jebel Akhdar. This province, including the great fertile and well-peopled chain of the "Green Mountains," is to the kingdom of Oman what the province of Ared is to that of Nejd, the backbone of the land. Here are the two towns of Nejwah and Bahhileh, formerly residences of the sultan; besides Zekee, Minah, and about seventy villages. The inhabitants are warlike, the women stately and beautiful; all belong to the sect of the Biadeeyah. The population is stated at about 600,000.

Belad Soor. Belad Soor, a coast district, said to be moderately fertile from Mascat to Ras-el-Hadd. The port of Soor is the only place of any note, but several small villages are said to exist near the coast. Population about 100,000; among them are the Benoo Aboo-Alee Arabs, famous for their brave resistance to our own troops in 1819-20.

Jaylan. Lastly, Jaylan, a wild region of which little is known, except that the inhabitants are uncivilised, and resemble in all respects those of Mahrah, with which province theirs is conterminous.

Population. The entire population of Arabia proper has been variously estimated; some authors make it reach 12,000,000, others reduce it to 7,000,000. Taking the approximate statistics above given, we find for the whole of central Arabia, including Jowf, Shomer, and Nejd, about 1,500,000 settled inhabitants, with 500,000 Bedouins or nomades; thus 2,000,000 may perhaps fairly represent the complete number. The east coast—Hasa, Bahreyn, Oman, and their adjoining districts—furnishes 2,500,000 more. Yemen is said to contain over 1,000,000: Hadramaut and Mahrah cannot be very populous: the Hejaz certainly is not. 3,000,000 is the maximum estimate of both taken together, nomades or villagers. To these must be added the tribes of the Sinaitic peninsula, and of the northern frontier. These may possibly bring the sum of the Arab population to 8,500,000, or even 9,000,000, with a quota of about one-fifth Bedouin to four-fifths of settled Arabs; to such small numerical proportions has the nation shrunk that once ruled by land and sea from the Indus to the Atlantic, and that even now, by its religion and institutions, gives the law to one-eighth of the human race.

History. The history of Arabia and its inhabitants naturally divides itself into two distinct and even dissimilar periods, that, namely, which preceded the era of Mahomet, and that which followed it. Each of these two periods, though comprising in its extent several minor phases and fluctuations, now of advance, now of retrogression, bears, however, a well-marked general character of its own. The first of the two periods is distinguished as one of local monarchies and federal governments; the latter commences with theocratic centralisation dissolving into general anarchy.

Prehistoric myths. The unrestrained imagination of Arab chroniclers has indeed added to their annals a third or pre-historic tract, peopled with heroes and giants, men of renown, sons of Anak, much resembling those who figure in early Jewish records, and, it may be not unfairly presumed, of analogous authenticity. To such belong the fabulous tribes of 'Ad in the south, of Thamood in the north, and of Tasm and Jadis in the centre of the peninsula. Very gorgeous are the descriptions given of "Irem," the "city of pillars," as the Koran styles it, supposed to have been erected by Shedad, the latest despot of 'Ad, in the regions of Hadramaut; and which yet, after the annihilation of its tenants, remains entire, so Arabs say, invisible to ordinary eyes, but occasionally, and at rare intervals, revealed to some heaven-favoured traveller. Vague reports of the colossal ruins of Egyptian Thebes and Karnak probably originated the fancy. To Thamood are ascribed the more substantial traces of rock excavations in the north-western Hejaz; while Tasm and Jadis are described as more scenite or Bedouin-like in their manners and mode of living. Mahometan tradition, a mere travestie of the Jewish, and mostly derived from rabbinical sources, has attempted to construct a pseudo-genealogy of a Noachian character for every one of these imaginary or vanished clans. Further yet, it has, in its eagerness to find a confirmation of its own central idea, everywhere ascribed their extinction to supernatural wrath, brought down on them, now by the rejection of some apocryphal prophet of the Divine Unity, now by atrocious misdeeds like those recorded of the inhabitants of Canaan or the Cities of the Plain. The sober historian, however, will, in the absence of any reliable evidence, documentary or monumental, abstain from pronouncing either on the character of these aboriginal tribes, or on the manner and causes of their disappearance.

Old Arab monarchies. The first dawning gleams of anything that deserves to be called history disclose Arabia wholly, or nearly so, under the rule of a race of southern origin; the genuine, or, as they are sometimes termed from a mythical ancestor Kahtan, the Kahtanee Arabs. These, again, we find subdivided into several aristocratic monarchical governments, arranged so as to form a broad framework or rim round the central wilds of the peninsula.

Kingdom of Yemen. Oldest and chiefest among the Arab monarchies was that of Yemen; its regal residence is said to have been in the now abandoned town of Mareb, in the extreme south. After a devastating inundation, referred with some probability to the first century of the Christian era, the seat of government was removed from the ruins of Mareb to Sanaá, a city which has continued the metropolis of Yemen to the present day. The Yemenite kings, descendants of Kahtan and Himyar "the dusky," a name denoting African origin, and each adorned with the reiterated surname of "Tobba," a word of African etymology, and signifying "powerful," are said to have reigned, with a few dynastic interruptions and palace revolutions, for about 2500 years; during which long period they commanded the direct obedience of the entire southern half of the peninsula; while, by their tribute-collectors, and by chiefs of kindred or delegated authority, they indirectly governed the northern. One of these monarchs is asserted, though historical criticism will hardly admit the assertion for fact, to have subdued the whole of central Asia, and even to have reached the boundaries of China; while another anticipated, so runs the story, the later and more authentic conquests of his race on the north African continent. In both these cases Arab chroniclers seem to have appropriated for their own rulers, not without some additional exaggerations, the glories and exploits of the Egyptian kings. But that theirs was a vigorous and in some respects a civilised government, is attested alike by the literary and architectural relics of their time. Their sovereignty was at last overthrown, 529 A.D., by an Abyssinian invasion, and was re-established 603 A.D. as a dependency of the Persian empire, till in the year 634 it was finally absorbed by Mahometan conquest.

Kingdom of Hira. Next in importance to the kingdom of Yemen came the subsidiary monarchy of Hira, or, more correctly, Heerah, situated in the north-easterly province of Arabian Irak. Its kings, a collateral branch of the royal race of Sanaá, governed the western shore of the lower Euphrates, from the neighbourhood of Babylon down to the confines of Nejd, and along the coast of the Persian Gulf. The duration of their empire, founded in the second century after Christ, was 424 years. This kingdom paid an uncertain allegiance to their more powerful neighbours, the Persian despots; and from time to time exercised considerable influence over the turbulent tribes of Central Arabia, till, like Yemen, it sank before the rising fortunes of Mahomet and his followers.

Kingdom of Ghassan. A third monarchy, that of Ghassan, lorded it on the north-west over lower Syria and the Hejaz: its independence was somewhat tempered by unequal alliances with the Roman, and subsequently the Byzantine empire. It was founded in the first century of the Christian era, shortly after the flood of Mareb; and its duration, till subdued by the all-conquering prophet, exceeded 600 years.

Kingdom of Kindeh. A fourth government, that of Kindeh, detached itself from Irak early in the fifth century, and united under its sceptre the tribes of northerly Nejd and even those of Oman, for about 160 years. Its kings were, like those before mentioned, of Yemenite origin; but their rule was weak and disturbed by frequent wars.

Flood of Arem. Much has been written by Arab authors regarding the great inundation, as they term it, of Arem or Mareb, possibly a tropical cyclone of more than ordinary destructiveness, like that of 1867 in the West Indies; and this event they love to assign as the proximate cause which dispersed the families of Yemen over northern Arabia, and led to the foundation of the kingdoms of Irak and Ghassan. But the reality of the events, physical or political, symbolised by the "flood of Arem," a counterpart, after its fashion, of the biblical flood, cannot now be well deciphered.

Prosperity of Yemen.

This is, however, certain, that the Yemenite Arabs, and especially those who tenanted the south of the peninsula, had during the period now cursorily sketched, attained a very fair degree of civilisation; that arts and commerce flourished, that wealth was accumulated, literature cultivated, and talent held in esteem. On all these points we have not only the uncertain and distorted testimony of foreign authors, such as Strabo, Pliny, Diodorus, Ptolemy, and the like, but the more positive though fragmentary evidence afforded by the national writings, chiefly verse, that have survived to our day. In its general character and institutions the kingdom of Yemen seems to have borne a considerable resemblance to the neighbouring one of the Nile valley, on the other side of the Red Sea, and, like it, to have reached at a very early epoch a relatively high degree of prosperity and social culture, from which, however, it had long declined before its final extinction in the 7th century. But the daughter-kingdom of Hira had, as was natural, something of a Persian tinge; while that of Ghassan took a more Byzantine colouring. Lastly, the nomadic element predominated in the ill-cemented monarchy of Kindeh.

The "Mustareb" or northern Arabs.

But while the sceptre of Yemen was yet, in one form or other, outstretched over the length and breadth of the land, and its children, the genuine or African Arabs, formed a complete and dense circle of population all around, the centre of Arabia remained the stronghold of a different though kindred race, composed of tribes almost wholly scenite, in their mode of living wild and ferocious; less susceptible of culture, but gifted with greater energy and concentration of purpose than their southern cousins. The latest recorded emigration of this branch of the Arab-stock had been not from the south but the north; and instead of the mythical Kahtan, they claimed a no less mythical Adnan, or his supposed grandson Nezar, for their ancestor; their language, though radically identical with that spoken by the genuine Arabs, was yet dialectically different in several respects, and nearer to the Syriac or Hebrew. Lastly, unlike the Arabs of the south, they had little disposition for agriculture, and even less for architecture and the fine arts; their instincts leading them to a pastoral and consequently a nomade life. The almost infinite ramifications of these "Mustareb" or "adscititious Arab" tribes lead ultimately up to five principal stocks. These were Rabeéah, which, however, laid some claim to a Yemenite kinsmanship in the east centre of the peninsula; Koreysh, on the west; Keys, or Keys-Eylan, and Hawazin, on the north; and Tameem in the middle.

Revolt of the northern Arabs.

History has left unrecorded the exact date of their arrival in Arabia; nor has she defined the period during which they remained tributaries, though often refractory, of the kings of Yemen. But in the 5th century of the Christian era there appeared among the Mustareb tribes a leader of extraordinary talent and energy named Koleyb, sprung from the tribe of Rabeéah, who having, in the fashion of William Tell, slain with his own hand the insolent and licentious tax-gatherer sent them from Sanaá, raised the banner of general revolt in Nejd; and, in the battle of Hazaz, 500 A.D., broke for ever the bonds of Yemen from off the neck of the northern or scenite Arabs. This done, Koleyb aspired to unite his countrymen into one vast confederacy, over which he himself exercised for a time an almost kingly power; but the scheme was prematurely broken off by his own assassination. Left now without a master, but also without a ruler, the "Mustareb" tribes found themselves involved in a series of wars that lasted during the whole of the 6th century, their heroic period. Yet in spite of severe losses sustained in battle by this or that particular clan, their power as a whole went on increasing, till at the dawn of the 7th century they had wholly absorbed the feeble kingdom of Kindeh, and encroached yearly more and more on the narrowing bounds of Yemen, Irak, and Ghassan. Nor, probably, would they have stayed till they had become absolute lords over the whole, or nearly the whole, of the peninsula, had there not developed itself from among themselves a still more energetic element which, before many years had passed, reduced both northern and southern Arabs alike to common obedience, then raised them to an unexpected height of common glory, and at last plunged them, along with itself, into one comprehensive decline and ruin.

Rise of Koreysh.

This new and potent element was the well-known clan of Fihr or Koreysh. Its families, of Mustareb descent, had at an early period, which subsequent and Mahometan chroniclers have tried to identify with the fortunes of the mythical Ismael, established themselves in the southerly Hejaz, near the town of Mecca, a locality even then the principal religious and commercial centre of Arabia. Already, at the beginning of the 5th century, the chiefs of Koreysh had, by a mixture of violence and craft very characteristic of their race, rendered themselves the masters and the acknowledged guardians of the sacred "Káabeh." This square stone temple, or rather shrine, itself of unknown antiquity, was situated within the precincts of the town of Mecca; and to it the Arabs were in the habit of bringing yearly offerings, and of making devout pilgrimages, for centuries before Mahomet had adopted it into the new ritual of Islam as the house of the true God. The keys of the consecrated building had originally been in possession of delegates appointed by the monarch of Yemen, but the Koreysh Arabs, having once obtained them, held them fast for ever after, and successfully repelled every effort, both of their own pagan competitors and of the invading Christian Abyssinians, 570 A.D., to recapture or to seize them. Their possession of the temple-keys not only gave the tribe of Koreysh a semi-religious pre-eminence over all the other clans of Arabia, but also placed at their disposal the treasures of gold, silver, jewels, and other offerings accumulated by the pagan piety of ages in the temple of Mecca.

Trade with Yemen.

A more important, as also a more creditable, source of wealth to the Koreysh clan was their Red Sea coast traffic, particularly with the ports of Yemen and Abyssinia. Jiddah has been always the chief westerly seaport, and Mecca, which is only a few leagues distant, the principal inland emporium of Arab trade; and under the dominating influence of the clever and active merchants of Koreysh, both places acquired special prosperity and importance.

Fair of Okad.

Lastly, only a day's journey distant from Mecca, was held, in the pre-Islamitic times, the great yearly fair and gathering of Okad, so called from the name of the plain where it used to assemble,—a national meeting, frequented by men of all conditions, from all quarters of the Arab peninsula, and lasting through the entire month of Dhoo-l-kaadeh, which in pagan, as subsequently in Mahometan reckoning, immediately preceded the ceremonies of the annual pilgrimage. Here horse-races, athletic games, poetical recitals, and every kind of public amusement, diversified the more serious commercial transactions of an open fair, that, in its comprehensiveness, almost assumed the proportions of a national exhibition; here, too, matters of the highest import, questions of peace and war, of treaty and alliance, of justice and revenge, were habitually treated by the chiefs of the northern Arabs; the "children of Mezar," to give them their favourite "Mustareb" patronymic, assembled in a sort of amphictyonic council, not less ancient, but, while it lasted, much more influential throughout Arabia than that of Thebes ever had been in classic Hellas. In this assembly the immediate local proximity of the Koreysh chiefs, joined to their personal wealth, courage, and address, assigned them a predominant position.

Origin of Koreysh.

Of their pedigree, which, as is well known, includes that of Mahomet himself, we have a carefully—too carefully, indeed, for authenticity—constructed chronicle, bringing the family tree up in due form to Ishmael the son of Abraham, of whom the Koreysh figure as the direct descendants. In the same artificial annals the Yemenite or genuine Arabs appear under the cousinly character of the children of Joktan, the son of Heber. On these points all Mahometan annalists are equally positive and distinct; all other Arab testimony equally adverse or silent. That a fable so utterly defiant of reasonable chronology, and even of the common sense of history itself, should have been adopted as matter of fact by Arab vanity and ignorance, is less surprising than that it should have found favour in the eyes of not a few, indeed of most, of our own European writers. Enough here to say that Mahometan chroniclers, by adopting as irrefragable historical authority the Jewish records, and then retouching them here and there in accordance with their own special predictions and tenets, have succeeded in concealing the truth of their own national identity and story from themselves and even from others, under an almost hopeless incrustation of childish fiction. A correcter version of Arab history and pedigree will, so far as possible, be given towards the end of the present article. To sum up, at the opening of the 7th century of our era, and coincidently with the first appearance of the prophetic autocrat and destined remodeller of Arabia, the overteeming life and energy of the great peninsula was, broadly taken, thus divided:—Foremost stood the tribe of Koreysh, with their allies, a powerful confederacy composed of tribes belonging to the Mustareb or northern stock, and occupying the upper half of the westerly coast and region. Next in importance came the countless independent and, thus far, uncentralised clans of the centre of the peninsula; they, too, mostly are of Mustareb origin, though a few claimed the more ancient and aristocratic kinsmanship of Yemen; but without, however, paying any allegiance to its rulers. Lastly, to the south, east, and north, still existed the noble but enfeebled relics of the old Yemenite kingdoms of Sanaá, Hira, and Ghassan, half-sunk into Persian or Byzantine vassalage, and exerting little authority, even within their own ancestral limits.

Contact with foreign nations.

But, however important to the country itself and in their ultimate results to the world at large, might be the events that took place within Arabia during the pre-Islamitic epoch, they had small bearing on the nations outside the peninsula. The Yemenite queen of Sheba's ambassage to Solomon, even if an historical event, led at least to no historical results; and with other coeval rulers and nationalities, Greek, Persian, and Macedonian, the Arabs rarely came into any other contact than that of distant and desultory traffic. Nor do the frontier skirmishes by which an Antigonus or a Ptolemy attempted, without success, to gain a footing in Arabia, deserve more than a passing notice; and Pompey himself, victorious elsewhere, was foiled on its frontiers.

At last, during the reign of Augustus, Ælius Gallus, the Roman

Expedition of Ælius Gallus.

prefect of Egypt, undertook a military expedition against Yemen itself, with the view of annexing that region, which report enriched with immense treasures, to the Roman empire. With an army composed of 10,000 Roman infantry, 500 Jews, and 1000 Nabatheans, he crossed the Red Sea in 210 galleys, and landed at Moilah, or Leuce Come, in 25° N. lat., near the modern Yambo. After some delay, the consequence of disease and disorganisation among his troops, he marched southward until he reached the inland district and city of Nejran, on the nearer frontier of Yemen. The town of Nejran he is said to have taken by assault, as well as a few neighbouring places, probably mere villages, of little note. Meanwhile a large force of Arabs had assembled to oppose him, but Gallus easily defeated them, and advanced to Mareb itself, then, we may suppose, the capital of Yemen. But the Roman soldiers, unaccustomed to the heat of the tropical climate, and much reduced in numbers, were incapable of laying siege to that town; and their general found himself thus forced to retreat, and recrossed the sea to Egypt without having effected any permanent settlement on the Arab side. Later attempts made by Roman governors or generals under Trajan and Severus were restricted to the neighbourhood of the Syrian frontier; and the ruined cities of Bosrah and Petra yet indicate the landmarks of the extreme southerly limits reached by imperial dominion over Arab territory.

Abyssinian invasion of Yemen.

More serious, and more lasting in its consequences, was the great Abyssinian invasion of Yemen in 529, when Aryat, son or lieutenant of the king of Abyssinia, landed in Aden with an army of 70,000 men, to avenge his co-religionists, the Christians, who had been cruelly persecuted by Dhow-Nowas, king of Yemen, himself a proselyte to, and an ardent propagator of, the Jewish code. The expedition was successful; Dhow-Nowas perished; Christianity was proclaimed; and for seventy-six years the Ethiopian conquerors retained subject to their rule the southern and richer half of the peninsula. Their king Abraha even advanced, in 569 A.D., the year of the birth of Mahomet, as far as Mecca; but beneath its walls suffered a repulse, which has been magnified by the Koran and Mahometan tradition into the proportions of a miracle. Persian assistance, furnished by the great Chosroes, ultimately enabled the Arabs under Seyf, son of Yezen, the last direct lineal descendant of the old kings of Sanaá, to liberate their territory from its dusky usurpers, 605 A.D.

Era of Mahomet.

The 7th century had now commenced, and before long the wonderful successes of Mahomet, or, in more correct orthography, Mohammed, 622–632 A.D., while they closed in one great centralising effort the era of Arab progress and development within the land, opened a marvellous phase of new activity and almost boundless extension without. The story of the great prophet and of his book, the obstacles he encountered and overcame, his labours, his reverses, his wars, his final and decisive success, belong to the separate article that bears his name. Here it may suffice to state that at his death, 632 A.D., the eleventh year of the Islamitic era of the Hejrah or flight, which he himself had founded, Mahomet left the entire Arab peninsula, with the sole and transient exception of the tribe of Tameem, and a few Yemenite clans, who for a short while preferred the revelations of his rival Moseylemah, the "false prophet" of Nejd, united under one sceptre, and in one creed.

Election of Abu-Bekr.

After the disputes which might naturally be expected from a general election and turbulent electors, and which, fomented by the ambitious and intriguing Ali, nephew and son-in-law of the prophet, ran so high between the "Ansar," or chiefs of Medinah, and the "Mohajireen," or those of Mecca, as to threaten the premature disruption and extinction of the Islamitic empire, Abu-Bekr, father of Ayeshah, the favourite wife of Mahomet, was chosen to be the great man's caliph,—"Khaleefah" is the Arab word—or successor. His reign lasted only two years; but it sufficed for the subjugation of the rebel tribes of Nejd and Yemen, the conquest of Damascus, and the commencement of the long career of victory that carried the arms, the language, and the institutions of Arabia over half the old world, from the banks of the Indus to the shores of the Atlantic, and from the burning sands of the mid-African desert to the green vineyards of pleasant France. These events we will now pass in cursory review.

Fall of Damascus.

Syria, distracted by long sedition and the bitter rivalry of ecclesiastical sects, fell a first and comparatively easy prey to the hardy invaders. Led by Khaled, the boldest and most talented among the early Mahometan generals, the Arab troops occupied Bosrah, overran the region of Hauran, and advanced against Damascus. The Byzantine army hurriedly sent by the Greek emperor Heraclius to the relief of the besieged town, was defeated with tremendous slaughter on the plains of Eznadin, where fifty thousand men are said to have fallen on the Christian side alone; and Khaled, following up his victory, instantly invested the capital of southern Syria. After a seventy days' siege, and in spite of the brave defence made by the Christian garrison under the leadership of Thomas the patrician, son-in-law of the emperor himself, Damascus was taken, half by storm, half by capitulation, on the 3d of August, 634 A.D., 13 A.H.; and amid all the vicissitudes of succeeding centuries has remained ever since, not only a Mahometan, but an Arab city.

Battle of Yamook.

Heraclius, who, unaware at first of the importance of the crisis, had hitherto remained almost inactive in Antioch, his north-Syrian residence and capital, now, roused to exertion, collected an army of 80,000 men, the greater number of whom, reinforced by 20,000 auxiliaries from among the Ghassanide Arabs, were led at first by the emperor himself, then by Manuel, a tried Byzantine general, to meet the ever-advancing Mahometans. These last, under the standard of Khaled, had already added Homs or Emesa, Baálbec or Heliopolis, and Hama, the Hamath of Scripture, to their list of conquests. They now fell back on a strong position behind the windings of the Yermook or Hieromax, a small stream issuing from the southern slopes of Mount Hermon, which now bears the name of Jebel-esh-Sheykh. The battle, in which Manuel took the offensive, Khaled the defensive part, raged for several days, and ended in the total defeat of the Greeks, 636 A.D., who are said to have lost upwards of 100,000 men, including Manuel himself, while at least 5000 of the victors remained on the field.

Conquest of Palestine Syria, and Mesopotamia.

Syria was now open to the Arabs; and Jerusalem, which, with the difficult and mountainous district of south-eastern Palestine, had hitherto been prudently neglected by Mahometan strategy, capitulated, 637 A.D., to the caliph Omar, who, apprehensive lest Khaled, if left to himself in Syria, should establish a semi-independent principality of his own, came thither in person to receive the keys of the holy city. Aleppo, and Antioch itself, soon followed; last the sea-coast, with Jaffa, Beyrout, Tripoli, and its many other towns and ports, was overrun; and within six years from the death of Mahomet the entire Syrian region, from Mount Taurus to the Red Sea, had become what, so far as language and usages are concerned, it has never since ceased to be, an Arab province. Within a short time after, Mesopotamia underwent the same fate; and the conquests of Tarsus and Diar-Bekr brought the Arabs in immediate contact with the uplands of Armenia and Koordistan, which for all succeeding times remained the ultimate limits of their permanent occupation.

Conquest of Persia.

With so much fighting on their hands to the west of the Euphrates, the Arab conquerors had for awhile refrained from attacking the great Persian empire to the east of that river, except by a few desultory and for the most part unsuccessful raids. Nor did the battle of Hira, in which the Arab armies under Jereer destroyed a large body of Persian troops, and evenged the previous losses of their countrymen, more than restore the apparent balance between the two empires. But Yezdegird, the last of the Persian monarchs, rashly provoked the extreme chances of a decisive war by sending his best general, Rustum, across the Euphrates with an army of 120,000 men, to offer battle to the Arabs, then commanded by Sáad, a native of Yemen, in the open plains of Kadeseeyah or Cufa, not far from the site of ancient Babylon. After four days' hard fighting, the Persians gave way, having lost the greater number of their men, besides the imperial standard, once the apron, so tradition said, of an Ispahan patriot blacksmith, and for many ages the palladium of Iran. The Arab general, profiting by the utter discomfiture of his opponents, crossed the Euphrates and the Tigris, took possession, almost without resistance, of the royal capital of Medain or Ctesiphon, where spoils of immense value were found, and pushed on to the more ancient metropolis of Susa, in Chusistan. But the completion of the work of conquest was reserved to his successor in the field, Nóoman Ebn-Mekran, who in the battle of Mahavend, 641 A.D., near Ecbatana or Hamadan, destroyed the last hopes of Persian independence. Yezdegird fled, to fall soon after by the hand of an obscure assassin; and his daughter, carried away captive, was taken in marriage by Hasan, the son of Ali—an ill-omened marriage, that, by its dower of Persian pretensions and sympathies, contributed not a little to the disunion and subsequent downfall of the Arab empire. The whole of Persia, from the Caspian and the Euphrates to the Indian Ocean, now received the religion and the rule, though not the language, of Arabia; Khorasan, Kerman, Mekran, Seistan, and Balkh, were next subdued, and for a while the Oxus became the eastern limit of Arab dominion. Thus before a century had elapsed the entire region west of the Indus obeyed the Arab and Mahometan caliph of Damascus.

Conquest of Egypt and Africa.

Westerly the first Arab conquest was Egypt. This important acquisition was made by Amroo, a man alike distinguished as a general and a statesman, during the reign of the caliph Omar. Farmah, or Pelusium, the easterly key of Egypt, was first reduced, and the conquerors, proceeding inland, assured their communications with Arabia and the Red Sea by the occupation of the Delta and Cairo. Thence, after much hard fighting, they reached and invested the city of Alexandria, and a fourteen months' siege was rewarded by the capitulation of that city, December 22, 640 A.D. No further resistance was offered; the Coptic population gladly exchanged the polished but heavy Greek yoke for the barbarous but lighter rule of the Arabs; and Egypt, like Syria, has remained socially, though not politically, a dependency of Arabia to the present day. The subjugation of northern Africa, including Tripoli, Carthage, Tangier, and the entire coast from the Nile to the Atlantic, occupied sixty years more; but in the battle of Utica, 698 A.D., the last remnants of the Byzantine empire were obliterated from the southern shores of the Mediterranean, and Africa was no less closely and permanently annexed to the Arab empire than Syria and Egypt had already been.

Conquest of Spain.

At last, at the opening of the 8th century, Musa, the talented and ambitious administrator of these vast provinces, received the well-known message of the traitor, Count Julian, that brought on the invasion of Spain. At the order of Musa, his lieutenant, Tarik, crossed the straits which yet bear his name, 711 A.D.; and soon after disembarking in Andalusia, met and defeated the armies of Spain in the decisive battle of Xeres, where Roderick, last of the Gothic kings, lost his crown and life. Tarik, 16,000 of whose soldiers are said to have remained on the field, requested and received fresh troops, with which he speedily reduced Malaga, Granada, Cordova, Seville, and finally the Spanish capital, Toledo, itself. Musa now followed in person, took the command somewhat abruptly from his lieutenant, received the submission of Saragossa and Barcelona, reached the Pyrenees, and reduced the whole of Spain, Galicia excepted, to an Arab dependency. His own recall and disgrace, the result of court intrigue and royal ingratitude, stayed awhile the further spread of the Arab torrent.

Invasion of France.

But in 731 A.D. the celebrated Mahometan general, Abd-er-Rahman, at the head of a numerous army, crossed the Pyrenees, and by the victories, or rather massacres, of Arles and Bordeaux, reduced the whole of France south of the Loire. But at Tours he met the main French army, commanded by Charles Martel, mayor of the palace, and founder of the Carlovingian dynasty. Here, in a bloody battle of seven days, the tide was turned. Abd-er-Rahman himself fell, and his troops were dispersed, and fled, never to return. Not long after, 759 A.D., Pepin, son of Charles, delivered France from the lingering vestiges of Mahometan rule. Spain, however, remained for more than five centuries an Arab settlement; and her language, literature, and usages bear even yet the imprint of those who ruled her so long. Sicily too, Candia, Rhodes, Cyprus, Malta, Sardinia, and even Corsica, with other islands of less note in the Mediterranean, became each in turn, though none for long, Arab possessions. In Asia Minor, on the contrary, on the shores of the Black Sea, and east of Samarkand, the Arab invaders, in spite of brave and reiterated attempts, two of which, 670 and 717 A.D., were directed against Constantinople itself, were never able to make good their footing. But at the close of the Benoo-Omeyyah dynasty, 755 A.D., their empire comprised the whole basin of the Mediterranean, with the exception of its northern side; in Africa its only limits were the great central desert, in Asia the plateau of Kobi and the Indus, and throughout almost all these regions the Arab element either remained absolutely predominant down to our own time, or has at least left distinct traces of its existence.

Extent of the Arab empire.

Internal organisation.

We must now give a brief glance at the internal condition and institutions of this vast empire, which were such as to afford from the very first no favourable omen of political stability. Mahomet, when dying, not only omitted to name a successor, but, worse still, designated no electors; and through all the centuries of Arab rule the conditions both of elective and of hereditary right were never accurately defined. Hence the early rivalries, already alluded to, between the "Ansar" and the "Mohajireen;" and hence, not long after, the yet more dangerous contention between the family of Omeyyah, from which Othman, the third Mahometan caliph, descended, and the kindred house of Hashim, the more immediate relatives of the prophet. Meanwhile, within the ranks of Hashim itself, Ali, nephew of Mahomet, and husband of Fatimah, his only daughter, denying every right of free election, advanced his own special title to the throne by the presumed claim of nearness of blood, a title persistently urged by his descendants, and for centuries a constant source of dissension and weakness in the empire. Nor, whilst the nomination of the caliph himself, the centre and keystone of the Arab political edifice, was thus left undefined, were the remaining details of the construction at all preciser in their character. No accurate line of demarcation separated the executive from the judicial, or these again from the financial department; no municipal organisations were established or even acknowledged; absolute despotism was the only form of government, whether primary or delegated, in the capital as in the provinces; actual resistance and revolt the only remedies against its abuse. Such an empire might conquer, but could not govern, at least for long.

Internal history. The first four caliphs.

These inherent evils manifested themselves by their unmistakeable bad effects from the very first. Once only, when Abu-Bekr died, 634 A.D., after only two years of reign, the elective accession of Omar, the austerest, but also the most capable of all the early Arab rulers, was sanctioned by an almost unanimous approval; though even then the restless intrigues of the ambitious and unprincipled Ali made themselves manifest. After a glorious reign of ten years, the conqueror of Syria, Persia, and Egypt, perished, 644 A.D., assassinated by a Persian slave, Firooz by name; and Othman, son of Affan, of the noble family of Abd-esh-Shems, was elected in his place. The twelve years of his administration were ceaselessly disturbed by the insubordination of Ali and his partisans, who at last, impatient of delay, broke into the residence of the ancient caliph at Medinah, and murdered him there, 656 A.D. Stained with blood, Ali usurped the throne; while Ayeshah, daughter of Abu-Bekr, and widow of the prophet, collected round her the avengers of the blood of Othman, and the first civil war of Islam was inaugurated by a hard-fought battle, known as the "Day of the Camel," near Bosrah, 656 A.D. Ayeshah was defeated; but the cause of Othman was soon after taken up by his talented kinsman, Muawwiyah, governor of Syria, who in the battle, or rather series of battles, fought near Sofeyn, on the upper Euphrates, 658-9 A.D., broke the strength of Ali's faction. Driven from Syria, Egypt, and Arabia, Ali retired to Cufa, where an assassin's dagger avenged on his own person the crime by which he had opened the way to ill-gotten and precarious power, 660 A.D.

Ommiade caliphs

Muawwiyah, left by his rival's death sole though not undisputed ameer-el-moomeneen, or "ruler of the faithful," fixed his seat of government at Damascus, where he and the fourteen succeeding princes of his line ruled for eighty-nine years. Victorious abroad, his dynasty, generally called by European authors the "Ommiade," from the name of Omeyyah, father of the race, was for its first forty years harassed by frequent insurrections within the limits of the empire. The initial disturbances from which all that succeeded directly or indirectly took rise, were due to the intrigues of the two sons of Ali, Hasan and Hoseyn, both of whom were deeply imbued with Persian superstition, and who thereby soon gave the schism that they headed a religious as well as a political character.

Revolt of Hoseyn the Ali family.

After the death of the lazy and contemptible Hasan, his younger and more active but equally faithless brother Hoseyn, raised the standard of revolt in the eastern provinces, where he hoped to gather round him his Persian auxiliaries; but before he could draw his followers to a head he was met at Kerbela, on the Euphrates, by the well-organised troops of the caliph Yezeed, son of Muawwiyah, and perished miserably, 680 A.D. His descendants and kinsmen, for there were many, continued, however, now one of them, now another, to revive the pretensions of their family; and for more than a century they disquieted the empire, especially on its eastern and southern frontiers, with sedition and rebellion. At last their evident defection from orthodox belief, joined to the extravagance and licentiousness both of their teaching and practice, so disgusted the Arab race that scarcely any adherents were left them, except among the Moorish tribes of northern Africa, where their influence, founded on the strangest impostures, predominated for a time, and in the still more congenial soil of Persia. There indeed the sect obtained a permanent footing and ultimate supremacy. Thus originated and thus was perpetuated the first and widest spread of Mahometan schisms; the adherents of the legitimate caliphate and the orthodox doctrine assuming the name of "Soonnees" or "Traditionalists," while the sectaries of Ali are known as "Sheéah" or "Separatists" to this day.

Revolt of Abd-Allah Ebn-Zobeyr.

More formidable, however, to the Damascus princes, though sooner extinguished, was the revolt of Abd-Allah, son of Zobeyr, a brave but narrow-minded leader, and nearly connected by blood with Mahomet himself. Supported by the townsmen of Mecca and Medinah, besides a great proportion of the northern or "Mustareb" tribes, he was for more than ten years acknowledged as caliph by half the Arab world, till slain by Hejjaj Ebn-Yousef, the greatest of the Syrian generals, during the storming of Mecca by the Damascene troops, 692 A.D. The intrepid but ferocious Mukhtar, at first a supporter of Abd-Allah but afterwards his rival, and head of the "Khowarij" or "seceders," maintained a separate revolt on his own account in Cufa, till slain in battle by Musáab, son of Zobeyr, brother of Abd-Allah. The "Khowarij," however—brave and well-meaning though visionary men, some of whom were nothing else than over-zealous Mahometan priests or reformers; others, sectaries of Ali and his family; others, again, free-thinkers of republican tendency—found a new and successful leader in the courageous Shebeeb, a native of Hasa, who for several years maintained their cause on the upper Euphrates, while the revolt of a large portion of the Ommiade army itself, in the extreme east of the empire, where the caliph's own general, Abd-er-Rahman, headed the insubordination, shook the empire to its foundations. But over these and other enemies triumphed the military and administrative skill of Hejjaj; and it was only under him, the scourge of rebels, and pillar of the Ommiade caliphs, 705 A.D., that anything like real internal tranquillity was even for a brief period given to the empire.

Decline of Ommiade dynast.

Half hereditary, half elective, the family of Omeyyah numbered fifteen successive princes on the throne, mostly men of talent, able administrators, and some of them distinguished authors and poets. But their personal merits were unavailing against the downward progress of disorganisation, the necessary result of an essentially defective system of government, and rapid territorial extension out of all proportion with the means of consolidation; and the latter years of their dynasty present a melancholy scene of turbulence and confusion. Then appeared a new enemy, more dangerous than any of the preceding, to the Damascus sceptre, in the person of Ibrahim, great-grandson of Abbas, the uncle of the Prophet, who after long and secret intrigues, now gave himself out as the acknowledged head of the family of Hashem, from old time the hereditary enemies of the no less noble family of Abd-esh-Shems and Omeyyah, and consequently the legitimate claimant of sovereign power. His cause was upheld by the terrible Abu-Muslim, a gloomy but talented fanatic, native of Khorassan, who raised on Ibrahim's behalf the standard of revolt in Kerman. Soon Persia and its adjoining provinces, despairing of finding to themselves a worthy leader among the frivolous descendants of Ali, joined the kindred ranks of the children of Abbas. Ibrahim, indeed, perished; but his younger brother, Abd Allah Abu-Abbas, more known in history as "Es Saffah," or "the Bloodshedder," took his place, and was proclaimed caliph everywhere to the west of the Euphrates. Syria, Arabia, and Egypt still held out for Merwan, the last of the Ommiade caliphs; but the great military talents, stained by remorseless cruelty, of Abu-Muslim, turned the scale. The decisive battle was fought on the banks of the river Zab, near Irbeel (the *Arbela* of classic history), 749 A.D., and the whole of Syria was soon after overrun by the black-turbaned armies of Persia. Merwan himself, after much unavailing display of personal courage, fled to Damascus, and thence to Egypt, where he was overtaken and killed by his pursuers, 750 A.D.

Fate of the Omeyyah family.

Urged on by the pitiless Abu-Muslim, who shortly after himself fell a victim to the suspicions of his own equally cruel but more treacherous master, the victorious Saffah sought out everywhere the members, however remote, of the Omeyyah family, and put them to death under circumstances of the most infamous barbarity. The very tombs of the dead were broken open, and the bones of the great Múawwiyah and his noble successors dispersed. One youth of the doomed house alone, Abd-er-Rahman by name, effected his escape to the still friendly provinces of Africa, and thence to Spain, where he founded the illustrious dynasty that reigned in Cordova over the Iberian peninsula for two centuries and a half.

Decline of Arabia.

But with the fall of the Benoo-Omeyyah dynasty and the caliphate of Damascus fell the prosperity of Arabia herself, never again to rise. Arabs of the noblest, wealthiest, and most gifted stock, descendants of the princely Abd-Shems, the head of Koreysh in pre-Islamitic times, the Ommiade princes had established the centre of their government in a city intimately connected by land and by sea, by commerce and by nationality, with Arabia proper and the Hejaz, and in steady adherence alike to the feelings and policy of their race, they always regarded their native country as the choicest jewel in their own imperial crown. They were Arabs first and caliphs afterwards. Hence it was from Arabia that they drew almost exclusively the officials of their world-wide administration, both for peace and war; the provincial governors, generals, collectors, judges, administrators of their nomination were all, or nearly all, of Arab blood; and the improvement or enrichment of Arabia herself, the facilitation and extension of Arab trade and commerce, and the encouragement of Arab talent, literary and artistic, were the foremost of their cares. Meanwhile the peninsula, obedient indeed to the caliph as to its supreme head, but retaining in great measure the local institutions of its hereditary government by chiefs and in tribes, enjoyed a degree of general tranquillity, and even of comparative unity, that it had never realised before, nor has ever since. Even the hereditary rivalry between the northern or "Mustareb" Arabs, who about this time assumed the title, which they still bear, of "Keysee,"—a title derived from the numerous and influential stock of "Keys-Eylan," and thence communicated to the rest—and the southern or "Yemenee" Arabs, a rivalry founded in diversity of race, fostered by long and bloody wars, and continued, though under certain modifications, to our own time, might, and often indeed did disquiet, but could not overthrow, the beneficial order of prevailing tranquillity.

Policy of the Abbaside dynasty.

With the accession, however, of the Abbaside caliphs, 750 A.D., the good days of Arabia came to an end. Though they also were, like their Ommiade predecessors, Arabs by origin, and indeed of the purest Arab blood, they owed their place on the throne, not to Arab partisans, but to the influence and the arms of the anti-Arab and eastern provinces, Persian, Tatar, and Turkoman, beyond the Tigris; whilst the Arab half of the empire had almost unanimously declared for their supplanted rivals. Hence the Abbaside policy rested on a non-Arab base; and its representatives, although descendants of Koreysh and Hashim, systematically neglected or even depressed the Arab element of their rule, while they strengthened and elevated the Irano-Turanian or central Asiatic. Their throne, at first transferred from Damascus to Hashimeeyah, the newly-founded residence of Abd-Allah Es Saffah, on the Euphrates, was soon after removed further east to the banks of the Tigris. Here, close to the ruins of the old Persian capital of Madain, the second Abbaside caliph, Almansur, laid, 760 A.D., the foundations of that great city which, under the Persian name of Baghdad, still remains a monument of his personal energy and of the policy of his race.

Decline of the Abbaside caliphs.

Within its walls, surrounded by Persian ministers or slaves, amongst whom the family of Barmek has attained a tragical celebrity, and by an armed body of Turkish or Turkoman guards, at first their servants, but before long their masters the descendants of Abbas held for a century the substance, and for four centuries more the shadow of a sceptre. Some of their names, and that of Haroon-el-Rasheed, 768 to 809 A.D., in particular, are connected with great events and famous memories, but the records of their reigns belong to Perso-Asiatic rather than to Arab history. Indeed, from the death of the eighth caliph of the race, El-Mostásim, 842 A.D., to the accession of the last of their dynasty, El-Mostásim, 1242 A.D., these princes were mere puppets in the hands of the Persian, Koord, Turkoman, or Turkish mercenaries, by whom they surrounded themselves as a protection against their own Arab subjects. Meanwhile province after province separated itself from their empire, and reasserted its own native character and independence, till in 1258 A.D. the pagan and Tatar chief Holagoo, grandson of Genghis-Khan, stormed Bagdad, and extinguished the decrepit dynasty of Abbas in the blood of the last caliph. Yet Arab genius, though deprived of political support, maintained by its philosophical and literary vigour through all those dreary centuries, nor has even in our own time wholly lost, a certain intellectual ascendancy in Baghdad and its vicinity.

Karmathian revolt.

Meanwhile the Arabian peninsula itself, neglected or despoiled by the Abbaside caliphs, had sunk year by year more deeply into clannish disorganisation, till the revolt of the Karmathians, about the end of the 10th and the beginning of the 11th century, detached Arabia definitely from the overgrown empire that she herself had founded. This revolt had been long preparing. Hatred of centralised rule, a strong attachment to local, tribal, and even in some places semi-municipal organisation, both joined to a deep underlying scepticism, had from the very first originated and fostered throughout Arabia a wide-spread, though covert opposition to the establishment of Islamitic despotism, and jealousy of the predominance conferred by Mahomet and his successors on their kinsmen of the northern and western tribes, and on Koreysh in particular, had united in secret antagonism to Islam and the caliphate the other tribes of the peninsula, but especially those of the centre, east, and south. Hence the Karmathian outbreak soon took the form of an Arab reaction against foreign and uncongenial influences and institutions, and being such, could hardly fail of substantial success. As to the special tenets professed by the Karmathians—so called from Karmath, their mystic founder, circ. 890 A.D.—they were, in their ultimate expression, pantheistic in theory and socialist in practice.

Disorganisation of Arabia.

From the sea-coast provinces of Bahreyn and Katar, its first avowed centre, the uprising, headed by its terrible leader Suleyman Abu-Jahir, spread rapidly over the rest of Arabia; and in the year 929 of our era Mecca itself was stormed, and the Káabeh ruined by his troops, while the sacred black stone itself was carried off to Hasa, where it remained twelve years. The feeble attempts of the Abbaside caliphs to check the movement proved utterly ineffectual; all was confusion, and for two centuries more a bloody partisan war, or rather an ever-recurring series of petty wars, devastated the peninsula. When this at last gave place to the quiet, not of peace but of exhaustion, Arabia, from Syria to Aden, was, with the sole exception of the narrow Hejaz coast-strip, detached in fact as in name from the pseudo-Arab empire of Baghdad, and had returned to its primitive independence. But by the same process the land had relapsed, hopelessly this time, into the semi-barbarism that invariably follows a prolonged vicissitude of petty tyrants, vicinal wars, interrupted communications, waste of life and property, and the fatal insecurity of universal lawlessness. Ease, wealth, trade, science, literature, all had perished from Arabia, till after a long anarchy, of which little memory is preserved, and that little of less interest, the country subdivided itself into the provincial sections that, with slight modifications, it has retained ever since.

Rearrangement of the provinces.

Oman, with the adjoining regions of Katar and Hasa, was organised into a semi-elective monarchy of a limited character, under the leadership of the Nebhan and subsequently of the Yáarebah clan; while its rulers, in opposition to the orthodox head of Islam at Baghdad or elsewhere, assumed the half spiritual title of Imam, and have since retained it. Yemen, the wealthiest and most populous territory of Arabia, split up into an infinity of petty provinces, governed each by a distinct prince, while some one or other would from time to time assert a transient sovereignty over the rest. The barbarous districts of Mahrah and Hadramaut on the south-east, with the mountain fastnesses of Nejd and Shomer, were abandoned to the anarchy of clannish alliances or feuds. The Hejaz alone, with the sacred territory or Haram of Mecca, under the headship of the "shereefs" or "nobles," the lineal descendants of Koreysh, retained some kind of constituted authority connected with the outer world, and paid a respectful but distant allegiance, sometimes to the government of Baghdad, more often to that of Egypt.

Fatimite dynasty in Egypt.

For, on the ruins of the Aghlabite dynasty, founded by Ibrahim Ebn-Aglab, the general of Haroon-el-Rasheed in North Africa, 797 A.D., with the inland city of the Keyrawan for capital, there had arisen, 909 A.D., a new kingdom, that of the Fatimites, so designated from one Obeyd-Allah, its originator, a real or pretended descendant of Ali and Fatimah. These Fatimites, able but tyrannical mystics, having united under their rule the whole of the north

African coast, invaded Egypt; and Moezz-Allah, their caliph, having, 972-3 A.D., driven the Abbaside governor from the shores of the Nile, established his own throne in the city of Cairo, which his victorious general Jowher had founded the year previous. From this capital he and his descendants ruled for two centuries more, not only over Egypt, lower and upper, but, though at the price of frequent wars, over Syria to the east and Tripoli to the west, till the last of the Fatimite caliphs, Adhid-Billah, was, 1171 A.D., dethroned by the Koordish conqueror Salah-ed-Deen, better known in history and romance as Saladin, the chivalrous opponent of our own Richard I. But though no Arab prince has ever since reigned in Egypt, the Hejaz with its sacred cities remained annexed to that country, and Yemen in part followed suit.

Turkish occupation. At last, 1517 A.D., the Turkish sultan, Selim I., conquered Egypt, and obtained from the last real or supposed surviving Abbaside kinsmen of the prophet a formal investiture of the Mahometan caliphate, which thus definitely changed the character of that office from national to politico-religious. On this occasion the shereef of Mecca presented the sultan with the keys of the city; and the Arab tribes in general, those of the east excepted, proffered their allegiance to the Ottoman government. This subjection, real in Hejaz and Yemen, nominal elsewhere, the country continued for half a century, till the shereef Muttahir, impatient of a foreign yoke, attacked and routed the Turkish force of occupation, then commanded by Murad Pasha, and for a short time re-established Arab independence. Selim II. sent fresh troops, who at first gained some advantages over the Arabs; but in 1630 the Yemenite chief Khasim expelled the Turks from the whole of his native province, and restored a shadow of the old Himyarite throne at Sanaa. Here, 1761 A.D., the celebrated Danish traveller, Niebuhr, found the

Kingdom of Yemen. Imam, as he was styled, of Yemen, governing thirty provinces, six on the coast and twenty-four inland, besides several smaller states; and possessed of an income, chiefly derived from the custom-dues of Loheya, Mokha, and other seaports, equalling, it was thought, £1,000,000 sterling per annum. The standing army was reckoned at 5000 men, mostly infantry. Subsequently, Wahhabee encroachments on the north, the British occupation of Aden to the south, and Egyptian invasion under Mehemet Ali and his successors, considerably weakened the power of the Imam of Sanaá, till in 1871 a Turkish army, sent from Syria, took the capital, and put an end to the Arab dynasty of Khasim. At the present date Yemen is a province of the Ottoman empire, though with every prospect of not long remaining so.

Hejaz. Between the Hejaz and the Ottoman government the yearly pilgrimage, with the accompanying largesses of the Ottoman sultans, formed a more enduring link; one interrupted, indeed, from time to time by occasional rebellions, but as often renewed by Arab neediness, till the province, with its sacred cities, was definitely annexed, though only for a time, by the great Egyptian usurper Mehemet Ali.

Other provinces. But in the rest of the peninsula, in Nejd, Oman, Mahreh, Hadramaut, and the other adjoining districts, the Ottoman claims were from the beginning of the 17th century absolutely ignored, and no collision was possible, because no point of contact existed. This state of things was, however, at last modified by the Wahhabee movement, one of the most important in the history of Arabia, and the end of which we have not yet seen. Of this a brief account must now be given.

Rise of Wahhabus or Abd-el-Wahhab. Born at the town of Horeymelah, in the centre of Nejd, 1691 A.D., Abd-el-Wahhab, or the "Servant of the Bountiful," had in early life travelled far in Mesopotamia and Syria, report even adds India, seeking knowledge in observation and the conversation of the learned, to whom his own superior intelligence gave him recommendation everywhere. Returning in mature life to the secluded quiet of his native land, he gave himself up to thought and study, mostly theological. Convinced by the comparison between what he read and what he had seen in his travels, and continued to see around him in Nejd itself, where hardly a vestige of Mahometanism remained, that the primitive faith of Islam had become considerably corrupted in theory and totally so in practice, and that Turks, Persians, and Arabs, were all of them in fact, though after different fashions, no longer true Muslims, but mere idolaters and polytheists, he determined himself to inaugurate a reform that should reassert the doctrine and practice of the Koran as they had been at the beginning.

Wahhabee reform. The invocation of saints, including Mahomet himself, a practice borrowed by Mahometanism from foreign example; the honours paid at the shrines and tombs of the dead; the use of intoxicating liquors; the wearing of silk and gold—to sum up, every belief or practice directly or indirectly condemned by the Koran, or even not sanctioned by it—with all these Abd-el-Wahhab declared open war. His special and notorious prohibition of tobacco, a prohibition rigorously observed by his followers, and which subsequently became in a manner their distinctive badge, must be attributed to an excess of sectarian puritanism; nor can it be doubted that hatred of foreigners, and of the Turks in particular, had a large share in the zeal manifested by himself and his disciples for what they not altogether wrongly, considered as in a peculiar sense the national or Arab religion it was a view that had the sanction of the Koran itself.

Like Mahomet, Abd-el-Wahhab commenced his preaching when about forty years of age, and, like the prophet, soon drew down on himself the persecution of those he failed to convert. Driven from Eyaneh, where he had established himself, by the hostility of its chiefs, themselves stirred up to persecution of the rigorous doctrines by the far-sighted Arav, governor of the neighbouring province of Hasa, he found refuge with the sheykh Mohammed Ebn Sáood, the warlike chief of Dereyeeyah, who put his sword and that of his clan at the disposal of the new apostle. The reform thus supported soon extended itself, partly by persuasion, partly by force; and when Abd-el-Wahhab died in 1787, at the advanced age of ninety-six, he had already seen his doctrines dominant from the coast of Bahreyn to the confines of Mokha and Aden.

Ebn Sáood Conquest of Nejd. Abd-el-Aziz. War with the Turks. His disciple and patron, Ebn Sáood, after many victories gained over the governor of Hasa and other enemies or rivals, died in 1765, leaving the whole of Nejd, now consolidated into one government under one head, to his son and successor Abd-el-Aziz, who, on his accession, now assumed the titles of Imam and Sultan. Under this chief the important provinces of Abu-Areesh, south of Mecca, and of Nejran, on the frontier of Yemen, were added to the Wahhabee dominions. These conquests, or rather annexations, naturally enough excited the alarm of Ghalib, the shereef or governor of Mecca, who by his representations succeeded in at last awakening the long negligent Turks to the danger which threatened their frontiers from the national and religious union of the Arab race. Orders were issued from Constantinople, and in 1797 an army of 5000 Turks, with an equal number of allied Arabs, advanced into Hasa, which had already become Wahhabee territory, and laid siege to Hofhoof, the capital of the province. But harassed by the Wahhabees and fearful of risking a general engagement, they retired without having effected anything except to provoke the bitter resentment of an enemy who had now learned not only to hate but to

Storming of Kerbela. despise them. The consequence was that the Wahhabees before long took the initiative; and in 1801 their collected armies invaded the territory of Baghdad, and laid siege to Kerbela, a locality famous for the tomb of Hoseyn the martyr, son of Ali, and a centre of popular Mahometan superstition. The town was stormed, the inhabitants massacred, and spoils of immense value were transferred from its shrines to the Wahhabee treasury. Victorious on the east, the Wahhabee arms were next directed westward; Taif, the well known pleasure-ground of Mecca, was invaded and subdued with

Taking of Mecca. great bloodshed in 1802; and in the April of the following year Mecca itself, though not till after a brave resistance, came into Wahhabee possession. Ghaleb fled to Jiddeh, the only place in Hejaz that held out against the invaders; and Sáood, son of Abd-el-Aziz formally assumed the government of Mecca, whence he dictated to the Porte the terms on which alone he declared that he would henceforth permit the observances of the yearly pilgrimage from all parts of the Mahometan world. Shortly afterwards he succeeded in person to the Wahhabee imamate, his father having been assassinated by a Persian in the mosque at Deréyeeyah.

Sáood's reign Under Sáood the Nejdee kingdom attained its greatest extension and prosperity. Internally its government was such as that of Arabia had been under the first caliphs and their Ommiade successors,—namely, a despotism regulated by the prescriptions of the Koran; and the revenues at Sáood's disposal fluctuated between £200,000 and £300,000 yearly. This sum he expended chiefly for military purposes. In 1804 he conquered Medinah, plundering the rich offerings accumulated by the superstition of ages round the prophet's tomb, besides treating the inhabitants of the town with great severity.

From this date till 1811, open war, in which the Wahhabees were generally successful, was waged between them and all their neighbours on every side, but especially against the Turks, whose Syrian possessions were ravaged sometimes by Sáood's best general Abu-Noktah, sometimes by his gigantic negro lieutenant Hark, up to Anah on the Euphrates, and within sight of the walls of Damascus. At this time, too, the inhabitants of Bahreyn and the adjoining coast having embraced Wahhabee doctrines, combined them with profitable piracy on the Persian Gulf, till the British expeditions sent from Bombay in 1810 and 1819 broke up the robber nest of Ras-el-Kheymah, and set bounds to the insolence of the piratical zealots.

For during these events the customary pilgrimage of Mecca and Medinah had been interrupted, the Wahhabees allowing none but such as conformed to their own doctrines and habits to approach the sacred cities. Thus the whole extra-Arabian Mahometan world was roused to indignation against the new and exclusive reform, and the Ottoman Porte, after some futile efforts of its own, consented to entrust the chastisement of the Arabs to its doubtful and already over-powerful Egyptian vassal, Mehemet Ali.

War with Egypt. In 1811 this cruel and treacherous but highly talented man began the work, and, in spite of many difficulties and even reverses, never faltered in it till it was fully accomplished. The details of the campaign that reduced Arabia, though only for a few years, to an Egyptian province, being well known, a very summary mention may here suffice.

Tousoon Beg's campaign.

Tousoon Beg, son of Mehemet Ali, commanded the first expedition. It was directed against the northern Hejaz, and landed in 1811 at Yembo, which town the Turks took and made a base of further operations. A severe check inflicted on them by the Arabs in January 1812 retarded their advance, but by the end of the year Tousoon stormed Medinah, and his troops made a frightful massacre of the Wahhabee garrison and inhabitants; to which atrocity the treacherous murder of 1500 more, who after holding out long and bravely in the town castle, had surrendered on terms of safe-conduct, was soon added. Meantime the intrigues of Mehemet Ali detached the shereef Ghaleb from the Wahhabee cause; and Jiddeh was treacherously surrendered to the Turks in 1813. Mecca and the Teif district were immediately occupied by Ottoman troops. Mehemet Ali now came over in person; and his troops having been reinforced by those of his son Tousoon, he felt himself strong enough to break his promises to the sheykh Ghaleb, whom he arrested, dispossessed of power, and sent to die in exile.

Mehemet Ali's campaign.

For a year and a half Mehemet Ali remained at Mecca, collecting his forces for a decisive blow. Meanwhile, in 1814 Sáood had died, leaving as successor his son Abd-Allah, a chief equal to his father in every respect except prudence, in which he was unfortunately deficient. Mehemet Ali having completed his preparations, left Mecca early in 1815 with a large army, and advanced towards Yemen; while the Wahhabees, who are said to have been 30,000 strong, occupied the mountain pass of Bisha on the way, and rashly hazarded a general engagement. The battle, in which Mehemet Ali displayed much personal courage, was desperate, and ended in the utter discomfiture of the Arabs, several thousands of whom were killed on the field. Mehemet Ali followed up his victory, and in a few months had reduced the entire mountainous district north of Yemen, besides taking alive as prisoners Bakrooj and Tami, two of the most renowned Wahhabee chiefs, both of whom, in violation of his promises, he made be put to death with atrocious tortures. But the exhaustion of his own soldiers obliged him to relinquish his further march south; he returned to Mecca, and in the summer to Egypt; Tousoon Pasha, left to conduct the war, concluded peace with the Wahhabees, and shortly after himself died of the plague. The treaty he had signed was disavowed both at Cairo and Constantinople; and in September 1816 the celebrated Ibrahim Pasha, adopted son of Mehemet Ali, landed at Yembo, and commenced the final campaign. For more than a year he exercised his troops in frequent but well-timed and generally successful skirmishes with those of Abd-Allah, who in person commanded the Wahhabee armies; while his crafty diplomacy, equal to that of Mehemet Ali himself, won over tribe after tribe to the Egyptian cause. Well supplied with provisions, and his flanks covered by his Arab allies, Ibrahim, in spite of a severe repulse beneath the walls of El-Rass, subdued the entire province of Kaseem, entered Nejd on the north-west by the pass of Shakrah, and in April 1818 appeared beneath the walls of the capital, Deréyeeyah, on which Abd-Allah with his forces had retreated.

...of the Wahhabee ...ion

The siege lasted five months, and was conducted with great ability by Ibrahim, whose military skill at last triumphed over the determined courage of the garrison and inhabitants. Not, however, till the town had been gradually reduced to a confusion of ruinous heaps did Abd-Allah consent to surrender, and then only on honourable terms, which, as usual, the conqueror granted freely, but with no intention of observing. The Wahhabee chief was sent under strong guard to Egypt, and thence to Constantinople, where, December 19th, 1818, he was beheaded in the public square in front of St Sophia.

Egyptian occupation of Arabia.

Deréyeeyah was razed to the ground by the conqueror, and remains at this day, like Eyaneh, a formless heap. The provinces of Hareek and Hasa submitted after slight resistance; and the whole of Arabia, Oman excepted, now lay at the mercy of Ibrahim, who showed none. After a bloody series of executions and massacres, he placed garrisons in all the strongholds that he permitted to remain standing; and Arabia had to submit to the military conscriptions and other exactions and oppressions that have ruined, and still ruin, every other province of the Ottoman empire, aggravated in this case by the licentiousness of the conquerors and the long outstanding mutual hatred of Turk and Arab.

Revival of Wahhabee power.

Ibrahim returning to Egypt, left Khaleel Pasha as vice-regent of Arabia, who for a while maintained despotic rule over the country. But Turkee, the younger son of Abd-Allah, who on the downfall of his family had fled to the mountainous fastnesses of Toweyk, soon organised guerilla bands, that, aided by the peasants, succeeded in rendering the central and eastern provinces of the land untenable by the Turks. The inhabitants of Hareek and Hasa were the first to throw off the yoke; and the town of Riad, celebrated as the birthplace, 1400 years before, of the prophet Museylemah, now became the restored Wahhabee capital. Turkee, like so many other Arab rulers fell the victim of an assassin, but his son Feysul succeeded to his ability as well as to his popularity and power. The Egyptian government, by this time at open war with the Ottoman, made several unavailing attempts to put down the revolt; but the wars between Mehemet Ali and the Porte in Syria and Anatolia diverted its serious attention from the less important, because poorer, acquisitions made by Ibrahim in Arabia, till in 1842 Khoorshid Pasha, the last representative of Egyptian rule, was, partly by force, partly by craft, for Feysul was a master in both, compelled to quit his frontier residence in Kaseem; and this populous province was re-annexed to the Wahhabee empire, while Aseer, throwing off foreign rule, returned to Wahhabeeism and independence.

Present condition of central Arabia.

Hasa, Hareek, the whole of Nejd, Kaseem, and the provinces adjoining Yemen on the north, with Aseer, were now re-united under the sceptre of Feysul, and a broad belt of Wahhabee rule thus again stretched across the centre of the peninsula, from the Red Sea to the Persian Gulf. But over Bahreyn, Oman, and Yemen, the Wahhabees, though they have frequently attempted it, have never been able to re-establish their former dominion; and in Shomer and Jowf to the north, between Nejd and Syria, a new kingdom of a different and much more liberal character, that of the brave and clever Telal, sprung up, and has since maintained its independence. Nor have the often-repeated Wahhabee inroads on Mecca and the Hejaz been attended with their former success. Still, within its actual though narrowed limits, the Wahhabee government has remained well-organised and strong,—a constant menace to its neighbours, and a genuine specimen, nor a wholly unfavourable one, of Arab autonomy. But in 1870, Feysul, already aged and blind, was assassinated, as his father had been before him, and the dissensions of his two sons, Abd-Allah and Sáood, the former of whom advanced the rights of first-born, the latter those of popularity to the throne, led to a civil war, and gave occasion to Ottoman interference. An armed force was sent, and advanced along the shore of the Persian Gulf into the province of Hasa, where it occupied the capital, Hofhoof. With this, however, its success terminated, and the difficulties of crossing the "Dahná" desert strip seem likely to place an effectual barrier to any further progress. Aseer, however, a stronghold of Wahhabeeism, has been invaded by the Turks, who have gained there some temporary and superficial advantages, while the new kingdom of Shomer, weakened by the untimely death of its accomplished prince Telal, has also offered facilities for Turkish interference, though not of a military description.

Oman.

To these varied changes the kingdom of Oman has for many generations remained in great measure a stranger. But its capital, Mascat, was occupied by the Portuguese in 1508, who retained it till the middle of the 17th century. It was then retaken by the Yáarebah princes, who had all along maintained their power in the interior, and now for a century more became the sole though not the undisputed rulers of Oman, which was at this time often harassed by Persian invasion. In 1737 the country was formally attacked by the armies of Nadir Shah; the principal towns were at last taken, the inhabitants massacred, and for four years Oman groaned under the Persian tyranny. A deliverer, however, appeared in the person of Ahmed Ebn-Sáood, of Yemenite origin, but not of the reigning family. By a series of daring deeds he succeeded in expelling or destroying the enemies of his country, and was in return elected Imam in the year 1741, since which time his family have occupied the throne of Oman. Under the Imam Sultan Saood and his son the Seyyid Sáood, the Omanee kingdom attained its greatest splendour at the beginning of the present century. Its power then extended not only over Oman and a large tract of the Arabian mainland, but also over Bahreyn, Ormuz, Larej, Kishm, and the other islands of the Persian Gulf; besides the coast of Katar, with its celebrated pearl fisheries, on the Arab side, that of Barr-Faris, with the harbours of Linja and Bander Abbas, on the Persian, and a long strip of African sea-shore, south of Cape Guardefui, with the islands of Socotra and Zanzibar. Sultan Sáood was killed in 1804, but his son, of the same name, proved his not unworthy successor; and though unable to prevent considerable encroachments of the Nejdee Wahhabees on the north and west of his dominions, saved Oman itself from conquest and annexation. He consolidated the Arab power in Zanzibar and the east African coast, and when he died in 1856, after reigning fifty-two years, he left the kingdom of Oman the most flourishing state in the entire Arabian peninsula. Its proximity to India has often involved this government in relations, sometimes amicable, sometimes hostile, with ourselves; but a detail of them need not detain us here. Suffice it to say, that on the death of Sultan Sáood, Zanzibar was, partly by British influence, detached from the Arab empire; while the death of the late Imam, Thoweynee, son of Sáood, who perished, assassinated by his own son, in 1866, inaugurated a period of civil wars, from which Oman is still suffering. Her Wahhabee neighbours, too, continue their restless attempts at encroachment on her western frontier, while Katar and Bahreyn, with their pearl fisheries, have been wholly lost to the Mascat sceptre.

Lastly, the Hejaz is at the present date absolutely under the Turkish government, while Aden has, ever since its first capture in

Ottoman power in Arabia.
